HENRY WILLOCK RAVENSHAW, Assoc.M.Inst.C.E., Mem.Fed.Inst.Min.Eng., "The Uses of Electricity in Mines." Two Lectures.
May 15, 22.

JUVENILE LECTURES.

Wednesday Evenings, January 4 and 11, 1905, at 5 o'clock.

CARMICHAEL THOMAS, Treasurer of the Society, "The Production of an Illustrated Newspaper."

CONVERSAZIONE.

The Annual Conversazione of the Society will probably be held on Thursday, June 29, 1905, Each member is entitled to a card for himself, and one for a lady.

PROCEEDINGS OF THE SOCIETY.

CHARTER.—THE SOCIETY OF ARTS was founded in 1754, and incorporated by Royal Charter in 1847, for "The Encouragement of the Arts, Manufactures, and Commerce of the Country, by bestowing rewards for such productions, inventions, or improvements as tend to the employment of the poor, to the increase of trade. and to the riches and honour of the kingdom; and for meritorious works in the various departments of the Fine Arts; for Discoveries, Inventions, and Improvements in Agriculture, Chemistry, Mechanics, Manufactures, and other useful Arts; for the application of such natural and artificial products, whether of Home, Colonial, or Foreign growth and manufacture, as may appear likely to afford fresh objects of industry, and to increase the trade of the realm by extending the sphere of British commerce; and generally to assist in the advancement, development, and practical application of every department or science in connection with the Arts, Manufactures, and Commerce of this country."

THE SESSION.—The Session commences in November, and ends in June.

ORDINARY MEETINGS.—At the Wednesday Evening Meetings during the Session, papers on subjects relating to inventions, improvements, discoveries, and other matters connected with the Arts, Manufactures, and Commerce of the country are read and discussed.

INDIAN SECTION.—This Section was established in 1869, for the discussion of subjects connected with our Indian Empire. Six or more Meetings are held during the Session.

COLONIAL SECTION.—The Section was formed in 1874 under the title of the African Section, for the discussion of subjects connected with the Continent of Africa. It was enlarged in 1879, so as to include the consideration of subjects connected with our Colonies and Dependencies. Four or more Meetings are held during the Session.

APPLIED ART SECTION.—This Section was formed in 1886, for the discussion of subjects connected with the industrial applications of the Fine Arts. Six or more Meetings are held during the Session.

CANTOR LECTURES.—These Lectures originated in 1863, with a bequest by the late Dr. Cantor. There are several Courses every Session, and each course consists generally of from two to six Lectures.

ADDITIONAL LECTURES.—Special Courses of Lectures are occasionally given.

JUVENILE LECTURES.—A Short Course of Lectures, suited for a Juvenile audience, is delivered to the Children of Members during the Christmas Holidays.

ADMISSION TO MEETINGS.—Members have the right of attending the above Meetings and Lectures. They require no tickets, but are admitted on signing their names. Every Member can admit *two* friends to the Ordinary and Sectional Meetings, and *one* friend to the Cantor and other Lectures. Books of tickets for the purpose are supplied to the Members, but admission can be obtained on the personal introduction of a Member. For the Juvenile Lectures special tickets are issued.

JOURNAL OF THE SOCIETY OF ARTS.—The *Journal*, which is sent free to Members, is published weekly, and contains full Reports of all the Society's Proceedings, as well as a variety of information connected with Arts, Manufactures, and Commerce.

EXAMINATIONS.—Examinations, founded in 1853, are held annually by the Society, through the agency of Local Committees, at various centres in the country. They are open to any person. The subjects include the principal elements of Commercial Education, and Music. Full particulars of the Examinations can be had on application to the Secretary.

LIBRARY AND READING-ROOM.—The Library and Reading-room are open to Members, who are also entitled to borrow books.

CONVERSAZIONI are held, to which Members are invited, each Member receiving a card for himself and a lady.

MEMBERSHIP.

The Society numbers at present between three and four thousand Members. The Annual Subscription is Two Guineas, payable in advance, and dates from the quarter-day preceding election; or a Life Subscription of Twenty Guineas may be paid. There is no Entrance Fee.

Every Member whose subscription is not in arrear is entitled:—

To be present at the Evening Meetings of the Society, and to introduce two visitors at such meetings, subject to such special arrangements as the Council may deem necessary to be made from time to time.

To be present and vote at all General Meetings of the Society.

To be present at the Cantor and other Lectures, and to introduce one visitor.

To have personal free admission to all Exhibitions held by the Society at its house in the Adelphi.

To be present at all the Society's *Conversazioni*.

To receive a copy of the weekly *Journal* published by the Society.

To the use of the Library and Reading-room.

Candidates for Membership are proposed by Three Members, one of whom, at least, must sign on personal knowledge; or are nominated by the Council.

All subscriptions should be paid to the Secretary, Sir Henry Trueman Wood, and all Cheques or Post-office Orders should be crossed "Coutts and Company," and forwarded to him, at the Society's House, John-street, Adelphi, London, W.C.

HENRY TRUEMAN WOOD, *Secretary*.

South Metropolitan Gas Co. (Sir George T. Livesey), Gold Medal.
Stothert and Pitt, Ltd. (Walter Pitt), Gold Medal.
Swan, Hunter, and Wigham Richardson, Ltd. (George D. Hunter), Gold Medal.
Wardle and Co. (G. G. MacWilliam), Bronze Medal.

PROCEEDINGS OF THE SOCIETY.

FIRST ORDINARY MEETING.

Wednesday, November 16th, 1904; Sir William Abney, K.C.B., D.C.L., D.Sc., F.R.S., Vice-President and Chairman of the Council, in the chair.

The following candidates were proposed for election as members of the Society:—

Aiyangar, S. Krishnasvami, M.A., Central College, Chamarajendrapet, Bangalore City, India.
Aldridge, Walter H., Canadian Pacific Railway Company, Canadian Smelting Works, Trail, British Columbia.
Alexander, W. W., The Town Clerk, Heidelberg, Transvaal, South Africa. (P.O. Box 201.)
Anderson, Robert Bruce, Assoc.M.Inst.C.E., 5, Westminster-chambers, S.W.
Attridge, Ernest William, Simons Town, Cape Colony, South Africa.

Austin, Henry B., J.P., Government Offices, Bloemfontein, Orange River Colony, South Africa.
Ayton, Ernest F., M.Am.I.M.E., Apartado Postal 141, Parral, Estado de Chihuahua, Mexico.
Ballantyne, William Smith, Mortgage-buildings, Pretoria, Transvaal, South Africa.
Balta, José, Ministerio de Fomento, Lima, Peru, South America.
Barnes, F. J., Portland Stone Quarries, Isle of Portland, Dorset.
Barton, Geoffrey Berkley, Guntakal, Southern Mahratta Railway, Madras, India.
Bellamy, Franklin J., Yeovil.
Bird, Frank Noel, A,M.I.Mech.E., Wellington Mills, Dardanup, Western Australia.
Black, Francis, R.B.A., Crofton, Mountfield-road, Church-end, Finchley, N.
Bodkin, Archibald Henry, 5, Paper-buildings, Temple, E.C.
Boot, W. H. J., R.B.A., Markeaton, Well-road, Hampstead, N.W.
Bourke, E. F., The Bourke Trust and Estate Company, P.O. Box 321, Pretoria, Transvaal, South Africa.
Brassey, The Hon. Thomas Allnutt, 4, Great George-street, S.W., and Park-gate, Battle, Sussex.
Buller-Allan, Edward, M.D., Maldon, Victoria, Australia.
Burns, Thomas, 25, Diana-street, Newcastle-on-Tyne.
Burton, Joseph James, Rosecroft, Nunthorpe R.S.O., Yorks.
Butler, Edwin T., 26, Craven-park, Willesden, N.W.
Carr-Calthrop, Colonel C. W., M.D., 51, Pembridge-villas, Notting-hill-gate, W.
Chand, Rai Bahadur Lal, M.A., Chief Court, Lahore, India.
Chilvers, George William, 59, Stile Hall-gardens, Chiswick, W.
Church, Harry, 138, Crystal Palace-road, East Dulwich, S.E.
Clark, Augustus, M.I.Mech.E., Recife, Pernambuco, Brazil, South America.
Clark, George Stirling, 35, Upper Belgrave-road, Clifton, Bristol.
Clayton, Charles E., A.I.E.E., City of London Asylum, near Dartford, Kent.
Cobbe, Hervic Nugent Grahame, F.G.S., care of Kalgurli Gold Mines, Ltd., Kalgoorlie, Western Australia.
Cock, Edward A. Langslow, Seremban, Federated Malay States.
Colston, Miss Lilian, 34, Curzon-street, Mayfair, W.
Cottingham, Captain Henry Langrishe, R.A., 70, Carlton-mansions, Maida Vale, W.
Dale, Thomas Henry, M.R.C.V.S., Government Experimental Farm, Potchefstroom, Transvaal, South Africa.
Däll, Alexander Percival, N.G.S.Ry., Secunderabad, Deccan, India.
Darby, Arthur Ernest, A.M.I.Mech.E., Town Hall, Wolverhampton.
Dickens-Lewis, George Edwards, Talbot-chambers, Shrewsbury.
Docker, Edward, Etaples, Pas de Calais, France.
Dollar, John A. W., F.R.S.E., 56, New Bond-street, W.
Dove, Frederick L., 15, Studd-street, Islington, N.
Ebstein, Mrs. Bertha, Leighton-house, Adrian-road, Stamford-hill, Durban, Natal, South Africa.
Edge, S F., 3, Whitehall-court, S.W.
Edmonds, Captain Richard James, H.M. Gun Wharf, Portsmouth.
Ekberg, Miss Annie Elizabeth, Doveton-street, Ballarat, Victoria, Australia.
Enraght-Moony, Francis, Resident Commissioner, Mbabane, Swaziland, South Africa.
Fennell, John Howard, Rio Tinto, Spain.
Fleming, Robert, 2, Princes-street, E.C.
Forrest, George Topham, County Architects' Department, County Hall, Wakefield.
Fox, Alfred, jun., Assoc.M.Inst.C.E., care of Señor J. E. Harmsen, Arequipa, Peru, South America.
Frodsham, Harold, A.I.E.E., "E.C." Powder Works, Bean, *viâ* Dartford, Kent.
Fullwood, John, R.B.A., Studio, Slinfold, Horsham, Sussex.
Furnivall, F., East India United Service Club, 16, St. James's-square, S.W.
Galbraith, David Rankin Shirreff, F.I.C., Galbraith Iron and Steel Co., Ltd., P.O. Box 371, Auckland, New Zealand.
Gardner, Richard Core, 173, Fleet street, E.C.
German, Bernard Foster, care of Messrs. Grindlay and Co., Calcutta, India.
Gibbings, Major Henry Cornwall Cotton, Junior Naval and Military Club, 96, Piccadilly, W.
Gledhill, Gideon, Northfield, Edgerton, Huddersfield.

The CHAIRMAN delivered the following

ADDRESS.

The annual address of the Chairman of your Council is an occasion on which he can express his views on passing events, even though they may have no immediate connection with the actual work of the Society of Arts. But as the Society takes cognisance of every thing that affects the progress, extension, and knowledge of arts, manufactures and commerce, I am in hopes that I may not be accused of taking for my subject a topic on which I ought not to touch. Last year, owing to circumstances which then existed, I felt I ought in my address to enter somewhat fully into the connection between commercial education and our examinations. I stated, amongst other things, that it appeared to me that the time must come when the Board of Education would have to be asked to consider whether it should not take over our examinations, for the good reason that the Society was actually undertaking a work of great public utility in examining the results of the instruction in commercial subjects largely given in evening schools which were subsidised by the Board. The prophecy that I made last year regarding the increase in the number of papers for this year has approximately been verified, as stated in our annual report, and I see no reason to doubt that the estimate I gave will be pretty nearly realised in the coming and immediate future years supposing no disturbing influence takes place. I should like to remark that the experience in science and art examination work indicates that the annual increase of students in evening classes in years when trade is bad has always been considerably larger then when trade is good, and it may be that in the coming year when trade is not in a flourishing condition, the increase may even exceed that which I estimated. In any case, as I have said before, the time must come before long when the numbers of candidates examined will be beyond the grip of the machinery which exists at the Society and then Government will have to be approached. But it is not only in the case of such examinations that the State should be asked to take a definite responsibility. I have long held that

there is a certain class of work performed by institutions which should undoubtedly be carried on by some department of the State, specially devoted to such work.

The work to which I refer is such as is not suitable, or to be expected from societies or individuals. It is work which is continuous and must expand in the flux of time, which is recognised by the public as useful, which is not and cannot be remunerative, which requires a staff larger than is required by the ordinary demands of a society, and which cannot be dropped without serious detriment to the public.

The functions of scientific societies are as a rule indicated by their names. Societies are formed to foster the advancement of certain particular branches of science by research. A research may be laborious and lengthy, but it is not necessarily continuous, and the funds of the society and the members are sufficient for the purpose. There are exceptions to such societies and these are found in two of the three oldest societies, one our own Society and the other the Royal Society. The one was formed for the encouragement of commerce, art and industry, and the other for the promotion of natural knowledge. I have already alluded to the examination work which answers to my definition, carried on by the Society of Arts, but there is even a still stronger case for the relief by the State of certain administrative functions which are at present carried on by the Royal Society. I may merely mention the fact that it is responsible for the administration of the Government grant of £4,000 a year for research, which by itself is quite proper, but it is also responsible for the National Physical Laboratory, and for the Meteorological Office. It seems to me self-evident that these two are institutions at all events which are of national importance and answer to my definition, and ought to be administered by a Department of State on the advice of a scientific body.

When there is some pressing need Government does administer branches of a department which has to carry out scientific investigation. Thus the medical branch of the Local Government Board has been laboriously and gradually built up. It is far otherwise, however, with that scientific work which has no department specially interested in or needing it, though it is for the public weal, as the State departments only exist for ministering to that weal, it appears that some department should be created or enlarged to take charge of them. This view, which I have long held, has been more than confirmed by the evidence given before a recent Committee, which the Treasury practically appointed, to consider the present position of the Meteorological Office, but limiting the recommendation to be made so far as the grant made to it is concerned. As the Committee's report is published there is no occasion for me to be reticent of what passed nor as to what conclusions the Committee arrived at. I need scarcely point out that the Meteorological Office is perhaps a better known public institution than many of those under State control. Its history is peculiar, and is worth sketching, for it shows that the State has always, in regard to it, been averse to taking any responsibility for scientific research, however utilitarian, preferring to place the burden on the shoulders of some already weighted society such as the Royal Society, and considers that it has done its duty when it gives grants in aid, usually inadequate after a short lapse of time to carry out the work. Such grants being stereotyped, proper and justifiable expansion become impossible. The Board of Trade in 1855 started what is called forecasting, under the well-known Admiral FitzRoy, having asked the Royal Society their opinion of the way in which it was proposed to make the observations. The Royal Society approved of the proposed plan.

On the death of Admiral FitzRoy the Royal Society were again approached by the Board of Trade as to what course should be pursued in regard to the organisation of meteorological work, which a committee appointed by them had recommended, and the Royal Society's reply was to the effect that "the collection and dispersion of observations were best entrusted to a scientific body furnished with funds," and "responsible to Parliament," but that "storm warnings ought to be managed directly by a Government department." I will not weary my audience as to details, suffice it to say the Treasury objected to the separation of research and storm warnings as proposed, though its necessity is evident on many grounds. The President and council of the Royal Society thereupon, in the self-sacrificing spirit which they ever show, appointed an unpaid standing committee to superintend the meteorological observations to be made for the Board of Trade, and a sum of £10,000 was placed at its disposal. The standing committee were known as the Meteorological Committee.

The Royal Society, in 1875, indicated in new negotiations entered into by Government that the Meteorological Office should be a Government department, with a man of science responsible, under a Minister of the Crown at the head of it; but failing that, a Meteorological Council should be formed. This last, the bad alternative, was adopted in 1877, the Treasury being careful to avoid any action which might have a semblance of giving the Council or any of the staff any Government status. With the exception of the addition of a few hundred pounds given for a special object, the grant to the Meteorological Council has remained at the same figure as then allotted, viz., £15,000. The needs of the forecasting and oceanic meteorological branches, it may well be supposed, did not remain stationary, though the grant, out of which this continuous work and research had to be paid, did, neither did the men who composed the staff of the office remain at the same age between 1877 and now, and the question of pensioning those who have done good service became a pressing matter in 1898. The Treasury having refused to treat the staff as civil servants, the Meteorological Council acting in accordance with the wishes of the Royal Society, were obliged to set aside a fairly large slice of the annual grant to form a pension fund, and economies were forced on them which have restricted, and will restrict not only the necessary research work but the very usefulness of the office unless some relief be given. Amongst other things, the Observatory on Ben Nevis was warned that the small pittance which it had annually received would be cut off, and I have no doubt that this warning served on a Scottish Observatory was the cause of the late official inquiry.

It is needless to say that in the intervening years advance in meteorological science has been greatly retarded in Great Britain by want of funds. Perhaps the latest example occurred in 1902, when there was a proposal to obtain further information about atmospheric currents and conditions by the use of balloon and kite observations, an international scheme of work being contemplated. The small sum of £500 a year would have been necessary to carry out this research, but the Royal Society was obliged, on behalf of the Meteorological Office, to reply that they had no funds, a reply which it would have been difficult to make had the Meteorological Office been part of a Government department. Let us look across the water at our American cousins and see how they regard the science of meteorology, and whether or not it is important enough to attach it to the State. According to evidence given to the committee, the Weather Bureau in America, corresponding to our Meteorological Office and forming part of the Department of Agriculture, was spending £230,000 a year on the same work as that of the Meteorological Committee, whose funds at the maximum were confined to £15,300. In Germany, where very large sums are spent on the oceanic part of meteorology, it is a part of the Navy Department. We, with our splendid navy and mercantile marine, surely ought to see that this part of meteorology is as well cared for as it is in Germany, and that there is no lack of funds. The evidence given before the Committee showed that without the help of the hydrographic branch of the Navy the work could not have been carried on with anything like success. I am not intending to enter into a discussion of meteorological science, but it has been pointed out that if forecasts are any good (and we have it on record that from 68 and 75 per cent. of them are successful) they ought to be made as good as possible. There is no doubt that kite and balloon observations, and the use of wireless telegraphy in mid-ocean would give a still higher percentage of successful forecasts. But the additions must remain in abeyance owing to the money limit which has been fixed at the same standard for so many years.

Again, we find that a very large item of expenditure by the Meteorological Office is the cost of telegrams. It has to pay the same price for the use of the Post Office telegraphs as any private individual, whereas every Government office has the free use of the wires, and has not to consider whether a telegram runs to 12 or 120 words, or whether it sends one or 100. The main object of the Meteorological Office is to assist the public, and this is the same as that of Government departments, yet the one is hampered by the cost of publishing information (which to be of the greatest use must be transmitted at once) whilst the other is not. The view of the committee which sat was strongly that this disability ought to be removed, so that wide publicity to weather reports, especially in harvest time, should be given. Finally, the committee almost unanimously reported in favour of the office being attached to some Government department, and proposed that this should be the Board of Agriculture, a department which at present is not overweighted.

I must remind you that our great Indian dependency has been more alive to the question of meteorology than we have at home; but I trust that, backward as we are, we may, before long, attain that excellence of administration which the Indian Meteorological Department has exhibited under its present and past able administrators.

What Government intend to do with the committee's report I do not know. Judging from previous history there seems to be a dread at the Treasury of any of the present departments having more to do with science than is absolutely forced upon them. Perhaps this is natural. The lay official mind has, with some few exceptions, never fully grasped the importance of orderly and continued scientific investigation in order to increase national prosperity. It recognises it in a way, for its need is continually brought before them by the Press, but to it the easiest plan is to leave all such investigation to societies. In Great Britain it has never been realised that to foster such work is a duty of the nation. We have ignored the very patent fact that in free America and in other countries the necessity of annexing to the State all utilitarian research (when such research is carried out with the definite object of public usefulness) is fully recognised. I am not proposing for an instant that the work which is carried out by individuals or societies should be curtailed, but there are questions which are too large, too expansive, and bearing too much on the public weal which should be dealt with in Great Britain as it they are (say) America.

I suppose that Treasury negotiations will be opened with the Royal Society, who are now responsible for the Meteorological Office, and I should not be very much surprised if the same class of correspondence which was brought before the committee takes place in the present as it did in the past, If the Royal Society are wise, as I hope they will be, and not too willing to give way, as they often are, they will utterly refuse to be responsible for the meteorological observations, seeing the inadequacy of the sum placed at their disposal for the purpose of that office, and will support the committee's views, that it should form part of some Government department.

I have only so far referred to the Meteorological Committee, but, at all events, there is the other institution, which I have already mentioned, the National Physical Laboratory, which should come into the same category of quasi-public departments.

The necessity of a National Physical Laboratory was pointed out in 1891, by Sir Oliver Lodge, in his address as president of the Mathematical Section of the British Association, and this was further emphasised by Sir Douglas Galton, the President of the Association in 1895. Men of science, and heads of large industries pressed Government for aid in establishing such a laboratory, which was to standardise and verify instruments for testing materials, and to determine physical constants. Such a work as this, was far beyond the scope or means of any society, and yet, for the advancement of trade, the time had come when Great Britain sought to rely on its own resources for obtaining accurate standardising, and not to be forced to seek it abroad in establishments founded and supported by foreign States. At the head of the Government of the day was Lord Salisbury, whose well-known sympathies for science made him take a favourable view of the project, and the result was that the Government consented to help. The Government intended to be and was generous to it at its start, as it, no doubt, intended to be to the Meteorological Committee in the first instance. It has given the National Physical Laboratory buildings, and a sum of £19,000 to make the additions to them, which were absolutely necessary to commence with. It granted £4,000 a year for four years, and afforded assistance to it through the Office of Works. The National Physical Laboratory is under the ægis of the Royal Society, is controlled by a general committee of experts and an executive committee chosen from the former. They have Lord Rayleigh for its chairman and the great advantage of the presence of the Secretary of the Board of Trade as one of its most active members.

The term of years for which the grant was made runs out in March next, and its financial position has to be reviewed by the State through the Treasury.

Its existence and development has become a necessity through the excellent work that it has already done. Taking the year 1903, 1,340 tests were made for the public in subjects very diverse in nature. Thus tests were made for resistance coils, electrical supply meters, varieties of thermometers, gauges, density determinations, capacities of glass vessels, examination of specimens of metal, steel analysis, incandescent lamps, photographic lenses, vacuum

pressure gauges, strength of materials. It appears also that 29,477 instruments were verified, and the remark in the committee's report is one of interest in regard to the last numbers. They say, "It will be noticed that there is a fall of 3,500 in the number of clinical thermometers tested" in comparison with the previous year. *Verbum sap*, Great Britain was at war in that year, so that the services of the National Physical Laboratories were utilised amonst other things for Government. But it is also mentioned that there is work of first-class importance to the public which it has been forced to refuse owing to lack of funds. Standardising is not a luxury in the present day, and England has suffered much in its trade owing to the want of it.

I cannot do better than quote a German Press comment which the director, Mr. Glazebrook, also quoted in his paper on the Laboratory at the recent meeting of the British Association. The *Deutsche Mechanische Zeitung*, in June of this year, when commenting on the figures I have here given, writes:—"Our German instrument-making trade has every cause to watch carefully the development of the National Physical Laboratory, and to take timely precautions before the advantages which it has already secured against English competition are too seriously reduced." I suspect if more aid be not promptly given, that the precautions they may propose to take will be unnecessary. They may then look with satisfaction at their own bureaux, which they know are properly equipped and imperially supported. The following table will show the amounts granted by the different States in regard to these laboratories:—

Here we have a direct comparison of grants and turn-out of work. Great Britain, I think I may say, has no reason to be ashamed of the work, though it has of the grants. In connection with the results given in the Table, I may point out that France and the United States started their institutions after the inauguration of our own laboratory. It may be they profited by our mistakes, or, more likely, viewed the importance of the work to be carried on from a higher standpoint than ourselves. Nevertheless, with only the example of Germany to guide them, and probably entertaining the opinion that German views of scientific research are extravagant, I think, as I have said before, that the Treasury were generous at the time, but with the later experience of what France and the United States have since done, a liberal review of the further needs of the Laboratory should be entertained.

The idea of making any such institution a State institution, it may be supposed, was never entertained by the Government, such a notion being foreign to existing precedent. The precedent—bad precedent too—had to govern the situation. We have only to look across the Atlantic to see how our Anglo-Saxon cousins treat such matters. There, institutions such as I have here described, are part and parcel of a State department, and have a handsome annual grant allotted to them. The Government of the United States recognised the public need, and so did Congress, with the result that the public need is catered for by a public department as it should be.

In regard to the National Physical Labora-

Country.	Name.	Lost.		Annual Grant.	Receipts from annual work.	No. of tests made.	Staff.

* The annual grant was made before the work was started, and any balance left after paying salaries I believe was available for apparatus.
† In these cases the State takes the fees.
‡ For the 1st year.
§ Includes the Observatory Department.

tory, it is no secret that at the present moment it is hampered by want of funds for equipment and staff. Its refusal of work has only proceeded from this cause. The report which it issued showed that its expenditure had been larger than its income of £9,000, an income which is derived from a variety of sources:—Treasury grant, £4,000; Gassiot Fund, £400 (about); from Meteorological Committee, £400; fees, &c., £4,200 (about). In addition to this there has been £1,200 in donations. It is quite natural and right that the commercial and scientific position of such institutions should be reviewed from time to time, but surely it is better that its necessities should be recognised annually as in America rather than every five, ten, or twenty years, as it may be with us. If progress such as is necessary, and is expected from them, is to be made, their financial wants should be known and considered at much shorter periods.

Whether the Laboratory can become self-supporting is a matter of doubt to my mind. Even if it should be so, that is no reason for taking it away from State control, which always gives an impress to decisions, and it is a pledge that gain is not its only object. Certainly it would never arrive at the proportions that the huge more than self-supporting department, the Post Office, has arrived at. The example of Germany, where the State takes the fees, and supports the institution, is worth following.

I might refer to researches in solar physics also, which are carried out in the iron shanties at South Kensington, under the control of the Board of Education. The sum of £700 is allotted as a grant in aid for the work that is carried out there, and some of the staff are borne on the estimates, but if, as is to be believed, some of the tremendous problems of the causes of famine and plenty are dependent on the solar phenomena, then this work should be enlarged and encouraged. The expenditure of ten times the sum in one year may enable millions of pounds and lives to be saved which may be lost from the scant supply of needful means. It is true that the Solar Physics Observatory is under the Board of Education, but if its history were written, I doubt not that it would be found that from its very first inception (due to the repeated recommendation of a host of scientific men who foresaw something of what might be expected from it) the State wanted none of it. It may be said that if the Meteorological Office and the National Physical Laboratory were attached to a Government department, they might be starved in the same way. I do not believe it possible that such should be the case, for these two are of ostensible use to the ordinary public, and appeal to that most sagacious and popular person the man in the street, in a way that solar physics does not. The last deals with problems which are for future use, but it is intimately, most intimately, connected with meteorology. If the Meteorological Office becomes attached, as it eventually must be, to a Government department, the Solar Physics Observatory and staff should be attached to the same department.

There is another reason for attaching these institutions to the State, and this I have referred to in a previous paragraph, viz., the question of staff. Supervision must be scientific, and may be carried out by a scientific committee, changes in which caused by death or other causes are gradual, so that one scientific man replaces another, and the continuity of the supervision is maintained. Scientific supervising committees have a distinct advantage over any casual scientific advice which is called in by a Government office. The selection of advisers by a political or permanent head of of an office, is a task for which few are desirous to undertake, owing to causes to which I need not refer. The services of such a committee may be gratuitous, as it is in other advisory committees, and I may add that men of science, like men of standing in other walks of life, are ever ready to give their services for such a purpose. But when we consider the position of what ought to be the permanent staff, the conditions are completely different. I need not ask you whether the permanent staff of a Government office would care to work on the same terms as those of the staff of one of these quasi-public offices. If a man is in the former he knows that given health and fair service he will be entitled to a pension which at all events will enable him to end his days respectably, but if he is in the latter he knows that his pension, if any, will be inadequate, and that his salary will not bear comparison with that of men who, in somewhat the same position of responsibility, have a pension secured to them. He further knows that any pension he may get will be at the expense of those researches which he is supposed to aid. It has been said that the man who is without a pension should save. So he ought, but as everyone knows, there is always

an excuse, particularly where the salary is small, for spending money on which a man can lay his hand. It is far better for some one else to be provident for him. It is no use wasting time on platitudes as to thrift. Take an Englishman who has no private means of his own, and unless he has a strength of mind and capacity for self-denial which is possessed by only a very small per-centage of the populace he will leave the office a pauper and will probably become an object of charity.

If the Government will recognise the two institutions as doing essentially public service, and ask for the necessary funds, I believe Parliament would vote the supplies in the same ungrudging manner that Congress has done, as they would look upon them as a paying investment. Parliament realises most frequently before Government does the importance of any public work. The most happy solution of the problem would be (1) to have some department of State to which these and other kindred scientific institutions should be attached; (2) to have a scientific advisory board; (3) to distinguish clearly between grants for research, equipment, and material and those for staff.

The question may be asked as to what department these various institutions should be attached, and how such a branch of it as deals with science should be arranged?

Had the Department of Science and Art been in existence, I should not have hesitated in thinking that its functions should have been enlarged, and that, besides supervising science, technical, and art instruction, it should have had charge of the various institutions to which I have referred. Its very designation would have made it right and proper. To a certain extent the other departments recognised it as something more than an educational department. The Foreign Office and various other State departments frequently referred to it for purposes other than educational, and it had the advantage of having at its command the services of that distinguished body of men who are attached to the Royal College of Science, also its science examiners, who were mostly Fellows of the Royal Society. This department was thus enabled to give opinions and advice, which were the reflex of those of the upper ten of science. That department is now defunct and merged in the Board of Education, but still has atached to it, besides its educational colleges, the Solar Physics Observatory and the Geological Survey. I do not know whether the Board of Education would undertake any new duty when its hands are full with the new problems in education and its administration. If not, it would seem that the department, which has not as yet been over-burdened, would be the Board of Agriculture, which already administers the Fisheries, the Ordnance Survey, and Kew Gardens. In regard to the advisory board, all evidence points to seeking the advice of the Royal Society. The Treasury, India Office, and other offices refer matters for the consideration of the Council of the Royal Society. The references are many, and the Fellows willingly give their time on the various committees which are formed to report on the various subjects. The Royal Society is, as I have said, responsible for the annual grant of £4,000 given by Government, for research, for the Meteorological Office and for the National Physical Laboratory. As a Fellow of that society I am delighted that the Government recognise that it can justly have every confidence in its advice and guidance in all matters of science. It is the natural body to which to look for scientific advice, as it has in its ranks the most prominent men of science in all branches.

For this reason I should deprecate any departure from the existing practice of constituting it the adviser to the Government, and should any department be formed to take special cognisance of science, I think that it should have the council of the Royal Society as an advisory body. This would have the advantage of stereotyped advice not being tendered. The annual changes of a part of the Council whilst preserving continuity prevent grooves being made. The Council should, of course, have perfect freedom as to the method it might choose to adopt in arriving at any opinion. Nor would I propose any departure from the principle that the advice given should be in the future as in the past—unpaid for—except so far that the funds of the society should in no ways suffer, owing to its taking upon it this advisory position. Any extra expenditure due to this cause should be defrayed by the department it advises. Further, having this advisory body there should be at the head of that branch of the department some eminent man of science, with some scientific assistants, who would be enabled to understand in its full bearings the nature of the advice offered, for it is not always that even a really efficient Civil servant is enabled to distinguish between physics and medicine. There might be other dangers in not having a man of science as chief of the branch

which it is not needful to specify. I would even go so far as to say that the advisory board should be consulted as to obtaining a fit and proper person to fill the post. With a department looking after the administration of these bodies, there would be but slight danger that the charges on the estimates would not be appropriated as proposed. Such a department should be responsible for all scientific branches of work which were not strictly educational or departmental. Thus the Survey, the National Physical Laboratory, the Meteorological Office, and the Solar Physics would, at all events, be under its rule, and the administration of the grants in aid to the various bodies which now receive them should be part of its functions.

Another function that it should undertake would be to act as the Department of State, to whom all scientific societies would address themselves when matters affecting the public weal were brought before them.

It would be the link connecting Government with the world of science, a link which is non-existent at present, but which is much needed.

I trust that the facts I have placed before you show that the time ought to have arrived when something must be done to put these two public institutions on a proper footing worthy of the nation. Trade and industry, agriculture and health, are each and all dependent to a tangible extent on one or both of them.

I have perhaps strayed away from actual Society of Arts work too long, but the subject is one on which I feel strongly, but I must not conclude without a word or two on the present position of the Society of Arts. To-night's meeting marks the commencement of the 151st year of the Society's life. Its membership is now about 3,700, almost the highest number it has ever reached. The finances of the Society are on a sound footing, though the property of its own is but small, consisting as it does of such savings as have of recent years been set aside from current revenue. We have, however, to remember that the tenure of our present building may come to an end within a few years, when the need of providing a new home will be forced upon us, and this will no doubt be costly.

During the 150 years of its existence the Society has done much useful work, and none more useful than in the last few years. It occupies a position quite peculiar to itself, and is very wide in its aims. The King has recognised the part it plays and has played by remaining its President when he was Heir to the Throne, and continuing as its Patron at the present time.

We have as our President the Prince of Wales, and he has shown his interest in various ways in its welfare. I should like to see, in the fourth half century of its existence, the patronage which has been so graciously extended to it made patent by a prefix which would indicate it. Whether or not, the Society, I have no doubt, will play the same useful part in the coming fifty years as it has in the past, and I trust this year may be a year when it will have increased energy and vigour, and will at its close show that it has fully maintained its old prestige, of which we members are so justly proud.

After delivering the Address the Chairman presented the Society's medals which were awarded for papers read during last Session.

At the Ordinary Meetings:—

Sir Charles Malcolm Kennedy, K.C.M.G., C.B., "The Fiscal Problem."

Arthur Gulston, "Ice Breakers and their Services."

Robert Jones, M.D., B.S., M.R.C.P., F.R.C.S., "Physical and Mental Degeneration."

J. C. Medd, "Agricultural Education."

Thomas Tyrer, F.I.C., F.C.S., "The Need of Duty-free Spirit for Industrial Purposes."

William Pollard Digby, "Statistics of the World's Iron and Steel Industries."

Richard R. Holmes, C.V.O., "Early Painting in Miniature."

In the Indian Section:—

J. M. Maclean, "India's Place in an Imperial Federation."

Frank Birdwood, B.A., "China Grass: its Past, Present, and Future."

In the Colonial Section:—

Lady Lugard (Miss Flora L. Shaw), "Nigeria."

Alfred Emmott, M.P., "Cotton Growing in the British Empire."

In the Applied Art Section:—

Frank Warner, "The British Silk Industry."

Alfred East, A.R.A., "The Sentiment of Decoration."

Alan S. Cole, C.B., "Recent Developments in Devonshire Lace-making."

Sir STEUART BAYLEY, K.C.S.I., in proposing a vote of thanks to the Chairman for his interesting and valuable address, said he was not so sanguine as to believe that a Government of either party would be willing to enter the net which he had placed in sight of the wary bird, but if they would listen to the words of wisdom which had been uttered, they would be doing the country one of the greatest possible services.

Sir CHARLES KENNEDY, K.C.M.G., C.B., seconded the resolution, which was carried unanimously.

The CHAIRMAN acknowledged the compliment, and the meeting terminated.

MISCELLANEOUS.

CHEMICAL CONGRESS, LIÈGE, 1905.

Among the congresses arranged in connection with the Liège International Exhibition of next year, and with which the co-operation of the Belgian Government is ensured, that on Chemistry and Pharmacy, convoked by the Belgian Chemical Society and the Liège Pharmaceutical Association, is to be held at the end of July, 1905. It will promote a preliminary debate of the questions already submitted by the Berlin Congress of Applied Chemistry, 1903, to the deliberations of that to be held at Rome in 1906, and the decisions of the Liège Congress will be presented to the latter as national desiderata, while other questions raised by competent societies will be discussed and then referred to future congresses.

The Liège Congress is to be divided into the following sections:—1. General chemistry, physico chemistry; 2. Analytical chemistry, apparatus and instruments; 3. Industrial mineral chemistry, including metallurgy and industrial organic chemistry (sugar-boiling, fermentation, tanning, dyeing, &c.); 5. Pharmaceutical chemistry; 6. The chemistry of food substances; 7. Agricultural chemistry, manures; 8. Biological and physiological chemistry (application to hygiene and bacteriology); 9. Toxicology; 10. Practical pharmacy; and 11. Legislation and professional interests, deonthology.

The president of the organising committee is Prof. A. Gilkinct, of Liège, and the vice-presidents, Prof. L. Crismer and M. A. Delante. Further information can be obtained on applying to one of the secretaries—M. J. Raymond, 16, Place des Carmes, Liège, and M. J. Wauters, 83, Rue Souveraine, Brussels.

COAL IN THE SOUTH-EAST OF ENGLAND.

From circulars just issued by the Consolidated Kent Collieries Corporation, Ltd., it appears that the natural obstacles inherent to the piercing the water-bearing strata overlying this coalfield have been overcome, and a pitshaft sunk through from the surface to the coal seams.

The Kindt-Chaudron method by which the work has been accomplished is a Belgian process, first introduced into this country at the Cannock and Huntingdon Colliery (an extension of the Cannock Chase Coalfield) by Mr. F. W. North, a member of the Society of Arts, who was the consulting engineer for that enterprise, and was afterwards adopted by Mr. John Daglish at the Witburn Collieries, near the coast at South Shields. It reverses the usual process of sinking pit shafts by employing the labour at the surface instead of the bottom of the pit, and after having excavated the circular shaft to any reasonable depth by means of huge boring tackle, fitting it with cast iron cylinders to hermerically seal back all water by the compression of the Moss Box Gland, a unique part of the invention, without any labour being used below surface level.

The circular alluded to states that 1,100 feet in length of these cast iron cylinders weighing 4,000 tons have been successfully lowered into the pit which is now lined with this enormous iron cylinder. The usual tests having been applied, it is found to have effectually cut off the water bearing beds, so that it is now possible to proceed with the sinking of the working shaft without any trouble from water.

OBITUARY.

WILLIAM SAMUEL TROUNCE AND WILLIAM JOHN TROUNCE.—During the last week the Society of Arts has suffered a severe loss by the sudden death of the two chief members of the firm of William Trounce, printers to the Society for over fifty years. Mr. William Trounce, father of Mr. William Samuel Trounce, undertook the printing of the *Journal* in 1853, commencing with the first number of the second volume, and since he died, about thirty years ago, the work has been carried on by his son and grandson, both of whom have now died within a few hours of each other. The firm was originally established in Cursitor-street, Chancery-lane, and it was through the reputation they had obtained as law printers that they first became known to Mr. Peter Le Neve Foster, the Secretary of the Society of Arts in 1853. To a large extent, in consequence of their connection with the Society, the business developed, and in the seventies it moved to Gough-square, Fleet-street, where its offices have since remained. On the death of the founder of the firm, the control of the business passed into the hands of William Samuel Trounce, but he soon relinquished the actual management of that department connected with the Society of Arts to his son, William John Trounce, who carried it on till the day of his death. On Friday morning, 11th inst., he died suddenly from an apoplectic seizure, in

the thirty-eighth year of his age, having left his business on the previous night apparently in his usual health. On the following Monday night, the 14th inst., his father, Mr. W. S. Trounce, the head of the firm, also died suddenly, at the age of sixty-four, from heart failure, caused by grief at the loss of a son in whom he felt great pride, a pride amply justified by that son's great business capacity, courtesy and constant endeavour to carry out the wishes of those by whom he was employed. Mr. Trounce senior had for several years suffered from an affection of the eyes that necessitated his leaving the chief charge of the business in the competent hands of his son.

GENERAL NOTES.

COACHBUILDING PRIZES.—The Company of Coach Makers and Coach-harness Makers of London offer the following prizes for competition among British subjects engaged in the trades of coach making and coach-harness making and accessory trades, and members of drawing and technical classes in connection with such trades, resident in the United Kingdom of Great Britain and Ireland. Competition No. 1 (open to teachers of technical classes and previous prize winners in the company's competitions)—For drawings of a sound strong jobmaster's "Char-a-banc," to seat twenty passengers inside, safe and easy access behind; scale 4 inches to the foot; 1st prize, the Company's silver medal and £5 5s.; 2nd prize, the Company's bronze medal and £2 2s. Competition No. 2 (open to all, except teachers and previous prize winners in the Company's competitions)—For a drawing of a small light omnibus, to seat six persons inside, allowing 16 inches for each person (measuring the front of each seat); scale 4 inches to the foot; on paper 6 feet by 4 feet 6 inches; 1st prize, £5 5s.; 2nd prize, £2 2s.; 3rd prize, £1 1. Competition No. 3 (open to all)—For side view, plan and section drawings to full working size (coloured) of all the metal-work, exclusive of wheels, axles and springs, of an ordinary one-horse landau; 1st prize, £3 3s.; 2nd prize, £1 1s. Competition No. 4 (confined to coach trimmers)—For the best made pair of spring cushions for a brougham, any size, but the depth not to exceed six inches, the springs not necessarily steel. All other points of merit being equal, preference will be given to the shallowest in depth; scale 3 inches to the foot; 1st prize, £5 5s.; 2nd prize, £2 2s.; it is hoped that employers will assist by lending the necessary materials. Competition No. 5 (open to all)—The Master, Sir Alfred Seale Haslam, M.P., offers £10 10s., and the Company offer a silver and bronze medal and £5 5s., for a design for a complete motor-car to carry two people in the hind part and two on the driver's seat, including the chauffeur; the hind part to be convertible from an open to a closed carriage; side view and half plan; scale 3 inches to the foot; 1st prize, the Company's silver medal and £10 10s.; 2nd prize, the Company's bronze medal and £5 5s. Competition No. 6 (open to those under 18 years of age who have never won a prize in the Company's competitions)—For drawings in ink of a T cart, side view; 1st prize, £2 2s.; 2nd prize, £1 1s. The above prizes will be accompanied by the certificate of the Company.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, Nov. 21...Geographical, University of London Burlington-gardens, W., 8½ p.m. Dr. Hunter Workman, "Explorations in the Western Himalayas."

British Architects, 9, Conduit-street, W., 8 p.m. 1. Mr. L. G. Mouchel, "Monolithic Construction in Hennebique Ferro-Concrete." 2. Mr. W. Dunn, "Construction and Strength of Reinforced Concrete."

Camera Club, Charing-cross-road, W.C., 8½ p.m.

London Institution, Finsbury-circus, E.C., 5 p.m. Mr. E. Burton-Brown, "Recent Excavations in the Roman Forum."

TUESDAY, Nov. 22...United Service Institution, Whitehall, S.W., 3 p.m. Colonel G. E. Gouraud, "The First Regiment of Volunteer Cavalry, U.S.A., in the War of Secession, 1861-65; how, when and where raised, and some of its doings."

Medical and Chirurgical, 20, Hanover-square, W., 8½ p.m.

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Mr. J. F. Cleverton Snell, "Distribution of Electrical Energy."

Anthropological, 3, Hanover-square, W., 8½ p.m.

Colonial Inst., Whitehall Rooms, Whitehall-place, S.W., 4½ p.m. Mr. W. Staley Spark, "The Wealth of Canada as an Agricultural Country."

WEDNESDAY, Nov. 23...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. B. H. Morgan, "The Systematic Promotion of British Trade."

Geological, Burlington-house, W., 8 p.m.

The Faraday Society, 92, Victoria-street, S.W., 8 p.m. 1. Professor L. Kahlenberg, "Recent Investigations Bearing on the Theory of Electrolytic Dissociation." 2. Mr. F. J. Brislee, "The Potential of the Hydrogen—Oxygen Cell."

Royal Society of Literature, 20, Hanover square, W., 8½ p.m.

THURSDAY, Nov. 24...Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

London Institution, Finsbury-circus, E.C., 6 p.m. Mr. M. N. Drucquer, "Law and Custom of the Stock Exchange."

United Service Institute, Whitehall, S.W., 3 p.m. Lt.-Col. C. B. Mayne, "The Lance as a Cavalry Weapon."

Electrical Engineers, 25, Great George-street, S.W., 8 p.m.

FRIDAY, Nov. 25...Architectural Association, 18, Tufton-street, S.W., 7½ p.m. Messrs. J. T. Micklethwaite and E. Prioleau Warren, "Excavations in Westminster."

Clinical, 20, Hanover square, W., 8½ p.m.

Physical, Chemical Society's Rooms, Burlington-house, W., 5 p.m.

SATURDAY, Nov. 26...Botanic, Inner Circle, Regent's-park, N.W., 3½ p.m.

Journal of the Society of Arts.

No. 2,714. VOL. LII.

FRIDAY, NOVEMBER 25, 1904.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

NOTICES.

NEXT WEEK.

MONDAY, NOVEMBER 28, 8 p.m. (Cantor Lecture.) D. J. BLAIKLEY, "Musical Wind Instruments." (Lecture I.)

WEDNESDAY, NOVEMBER 30, 8 p.m. (Ordinary Meeting.) ARTHUR LEE, "The British Canals Problem."

Further details of the Society's meetings will be found at the end of this number.

COLONIAL SECTION COMMITTEE.

A meeting of the committee of the Colonial Section was held on Wednesday afternoon, 23rd inst. Present:—SIR WESTBY B. PERCEVAL, K.C.M.G., in the chair, Mr. Carmichael Thomas, Sir Frederick Young, K.C.M.G., with Sir Henry Trueman Wood, Secretary of the Society, and S. Digby, Secretary of the Section. The arrangements for the new session were considered.

THE LATE SIR FREDERICK BRAMWELL.

Mr. H. Graham Harris, lately a Vice-President of the Society, and for many years Sir Frederick Bramwell's partner, has presented to the Society a portrait of Sir Frederick, specially painted for the purpose by Mr. Seymour Lucas, R.A. The portrait was a posthumous one, and consequently could only be executed from such materials as could be supplied in the way of photographs, painted portraits, &c.; but, nevertheless, it is in the opinion of all who have seen it, an excellent likeness as well as an admirable work of art. In accepting it, the Council passed the following resolution:—

Resolved that the Council have much pleasure in accepting the liberal offer of Mr. Henry Graham Harris to present to the Society a portrait of the late Sir Frederick Bramwell, specially painted for the purpose by Mr. Seymour Lucas, R.A. In thanking Mr. Harris for the gift, they desire to express their admiration of the portrait and their satisfaction that the Society should possess a permanent memorial of one who was so closely associated with its work during a period of 30 years, and was so highly esteemed and regarded as Sir Frederick Bramwell.

ST. LOUIS EXHIBITION.

LIST OF AWARDS TO MEMBERS OF THE SOCIETY OF ARTS.

The following is additional to the list in the last two numbers of the *Journal*:—

Everett, Edgcumbe & Co. (Kenelm Edgcumbe), Gold Medal.

NORTH LONDON EXHIBITION TRUST.

In 1865, the Committee of the North London Working-classes and Industrial Exhibition (1864), presented to the Society of Arts a sum of £157, the balance of the surplus from that Exhibition, with a view to the award annually of prizes for the best specimens of skilled workmanship exhibited at the Art Workmanship Competitions of the Society of Arts. The Art Workmanship Competitions were discontinued after 1870, but since that date various prizes have been awarded under this Trust. Last year, prizes were offered to the students of the Artistic Crafts Department of the

Northampton Institute, Clerkenwell, and these have been awarded as follows :—

1st prize (£7 7s.), to Edgard Alfred Hatfull.
2nd prize (£4 4s.), to Lewis Edwin Stanton.
3rd prize (£3 3s.), to Edward Cockren.

THE BRITISH SCIENCE GUILD.

Under the above title an organisation has recently been established, the objects of which are briefly: (1) To enforce the necessity of applying scientific method to all branches of human endeavour, (2) to bring before the Government the scientific aspects of all matters affecting the national welfare, (3) to promote and extend the application of scientific principles, and (4) to promote scientific education. Sir Norman Lockyer is President of the Organising Committee, Lord Avebury the Treasurer, and Lady Lockyer the Honorary Assistant Treasurer. The Guild has already been joined by a considerable number of Fellows of the Royal Society and other influential persons, and its Committee have requested the Council of the Society to bring it under the notice of the members of the Society of Arts. The Council are in sympathy with the objects of the Guild, and they think it possible that some members of the Society may welcome the opportunity of associating themselves with it. They have therefore authorised the Secretary to receive the names of any members of the Society who may desire to join the Guild. The contribution required from subscribers is merely nominal, 2s. 6d. per annum, with an entrance fee of like amount. Further information as to its aims, objects, and organisation, can be obtained on application to the Honorary Secretary of the Guild, Mr. C. Cuthbertson, 9, York-terrace, London, S.W.

COVERS FOR JOURNAL.

For the convenience of members wishing to bind their volumes of the *Journal*, cloth covers will be supplied, post free, for 1s. 6d. each, on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

SECOND ORDINARY MEETING.

Wednesday, November 23, 1904; SIR JOHN ALEXANDER COCKBURN, K.C.M.G., in the chair.

The following candidates were proposed for election as members of the Society:—

Heraje, Pandoorung, Agar Bazar, Dadar, Bombay, India.
Hnyin, Tha, B.A., F.C.S., 13, Ladbroke-road, W.
Ince, Robert Self, 24, Deerbrook-road, Herne-hill, S.E.
Jagonnath, Ganpat, Lady Jumshedjee-road, Dadar, Bombay, India.
Jordan, Albert Edward, A.M.I.Mech.E., 6, High-road, Nungumbaukum, Madras, India.
Moorcroft, Harold, Marsh-parade, Wolstanton, Staffs.
Townsend, W. G. Paulson, 12, Clifford's-inn, Fleet-street, E.C.
Wheatley, William Humphrey, 40, Chancery-lane, W.C.

The CHAIRMAN, in introducing the lecturer, said that figures could be made to prove almost anything, but no figures could cover up the fact that England was not keeping its colonial trade. They must admit, to a certain extent, that they had been spoilt by their prosperity, and, by going to sleep had allowed others to steal a march upon them, but they could not shut their eyes to the fact that the rivals who were competing for colonial trade were not nations that they could afford to trifle with. Those nations were highly organised, and in these days of organisation, when every move should lead towards efficiency, it would be just as reasonable to oppose a Noah's Ark to a modern warship as it would be to expect an unorganised mass to compete successfully with nations who had organised their trade to the highest point of efficiency. The doctrine and practice of *laissez faire* were all very well when a nation had no competitors on its heels; but when others were coming close after it was necessary to turn on a full head of steam again. There was a squabble about all sorts of doctrines; professors and public men were perpetually wrangling over what ought to be done according to eternal principles, while the ship of commerce was sinking under their feet. That position of things wes too serious to be dealt with in a light way, because anything which affected trade affected the livelihood, the health, and the very lives of the citizens of a nation. He often wondered what any of the other great nations of the world, who understood the value of organisation, would do if they only had the chance of the mother country had with the trade of her colonies. Even if they had the shortly-coming reform in the fiscal system, other things would also be needful in order to re-establish English pre-eminence in the industrial and commercial world, and anything that awoke the intelligence of the people and made them think, would bring the advent of that needful step nearer every day.

The paper read was—

THE SYSTEMATIC PROMOTION OF BRITISH TRADE.

By Ben H. Morgan.

For a long time past an ever-recurring question on exchanges, in merchants' and manufacturers' offices, in all gatherings of men of business, has been this:—Is it well with British trade? And the answer—No one can pretend that it is satisfactory. I am not going to weary you with a long array of figures. Statistics have been accused of being used to prove anything, and I am afraid there is some truth in the charge. Figures certainly lend themselves to some manipulation, but facts are and will ever remain stubborn things, The broad facts of our present day trade in the Colonies and abroad, are marked plain in the statistical abstracts of our Board of Trade, and those facts cannot be altered by any amount of special pleading.

The total import trade of British colonies and possessions, as stated by the Board of Trade during the year 1888, amounted to £171,462,000, excluding the inter-state trade of the Australian colonies which, even then, was considerable. The share of this trade that fell fifteen years ago to the United Kingdom, was £100,576,000, as compared with £46,336,000 from foreign countries, and £24,550,000 from other British colonies. Well, in 1902, the last year dealt with in the official statistical abstract of colonial trade, the total volume of trade with these same colonies and dependencies had grown to £276,900,000. But of the enormous expansion of about 105½ millions that these fifteen years had witnessed, only about one-third fell to our share. The colonial portion of this trade had more than doubled, £24,550,000 being converted into £54,000,000; the expansion of that particular item no one in this room will grudge, I am sure. It is impossible, however, for a patriotic Englishman not to feel some uneasiness as he notes that the share of this colossal trade, taken by foreign countries, was no less than £89,900,000. In other words, while in fifteen years the importing capacity of the British colonial market has enormously increased, the share of that increase that fell to the United Kingdom amounted to barely one-third, whereas the exports of our foreign competitors had nearly doubled. Making all possible allowances for the imports into our Colonies of commodities which we cannot raise or economically produce in the United Kingdom, this balance-sheet cannot be viewed with any satisfaction. Broadly speaking, these foreign imports into the Colonies represent at least £25,000,000 to £30,000,000 of trade which should go to British manufacturers.

A statement of the import trade of the British self-governing colonies is no more comforting. According to the Board of Trade, the value of the latest imports of goods from all sources into the self-governing colonies is £113,000,000, of which £55,000,000 is the share of the United Kingdom, £47,000,000 that of foreign countries, and £11,000,000 the quota of British possessions. In the case of Australia, British exports in the last decade have actually dropped from £26,000,000 to £23,000,000, while the trade of foreign countries has risen from £6,000,000 to £11,000,000. Clearly there is something wrong about our export trade with the colonies. It must be remembered that these colonies are our natural markets, and any considerable diversion of trade from our own manufacturers, besides being an intrinsic loss, must necessarily result in a weakening of the ties that unite the colonies with the mother country.

I do not propose to give any statistics to show the condition in which our own export trade with foreign countries at present stands. An examination of such figures would, as we all know, reveal a still more unsatisfactory state of things.

It is only too plain that our export trade has not expanded, either in the Colonies or in foreign countries, in proper proportion to the expansion of the world's volume of commerce. In other words we are not getting our fair share of the world's trade, and I am afraid it is true that a very large body of trade has been and is being lost to us through causes which are entirely preventable.

What are those causes? I will say at once that I am not about to enter, in any shape or form, on matters fiscal. The great controversy between free trade and protection, which has raged in most civilised lands for some two centuries, and will, perhaps, two centuries hence, be as far from settlement as it is to-day, has indeed been lately raised in this country in an acute form. But at present this is essentially a political controversy, and with politics I am in no way concerned. The great issues involved in the question of colonial preference and of fiscal policy in general, can only be settled at the polling booths, and will, perhaps, not be finally settled till two or more general elections have passed

over our heads. Until, therefore, the country has definitely pronounced itself upon this point, it would be futile to drag fiscal questions into such a paper as this.

Moreover, whether we remain free traders or revert to protection, the expansion of our trade either in the Colonies or in foreign lands, must to a great extent depend on the energy displayed by our manufacturers and traders, on their technical proficiency, which will itself depend to a great extent on their technical training, on their ability to adapt themselves to the ever-changing conditions of foreign and colonial demand, and last, but by no means least, on the direction and organisation of our industrial and commercial forces by the State. Lord Macaulay, in one of his inimitable essays, remarked it was highly probable that the highest and lowest Churchmen, though hopelessly apart on the proper ritual for the Church of England, would be in perfect agreement as to any two sides of a triangle being together greater than the third side. In the same way, I should imagine that the most ardent free trader and the most convinced tariff reformer would agree that colonial and foreign trade is not to be captured by antiquated methods of commerce, by shutting our eyes to what is going on in the world around us, or by that sleepy indifference on the part of the State to the trade interests of the country which used to be known under the title of *laissez faire*.

The State and Trade.

There are still many traders, thoughtful men of business, who are not alive to the responsibilities of the State in regard to trade. Too many people seem to take it for granted that because the State interfered unwisely with trade in days gone by, therefore all Governmental action in regard to the body industrial and commercial is to be deprecated. It has been truly said that the edict of no Czar can call into being a Birmingham or a Manchester. But that is no excuse for leaving undone what may conduce to the building up of trade and commerce. Moreover, those who argue that the State has no right to interfere with the course of trade forget that the business of the country is interfered with in a hundred ways by the direct action of the State. What are factory acts, workmen's compensation acts, shipping legislation, adulteration laws, and so forth, but direct interference with the course of trade. It may be said that the activity of the State in this direction is called for by the highest interests of the commonwealth. That is doubtless quite true, but if the Government may legitimately impose restrictions that in certain cases hamper our commerce in competing for foreign trade, why is it not equally bound to promote trade, when such action can be taken at a reasonable expenditure of public funds, and above all with a maximum of useful effect? By this I mean that in promoting the interests of traders the State should act strictly on the principle of the greatest good of the greatest number. The bearing of this remark will be made clear by the consideration, in the course of this paper, of what the State may fairly be asked to do to assist manufacturers and traders in placing their goods in Colonial and foreign markets.

The Control of Shipping Monopolies.

We will, first of all, see what the State has done and might do in regulating the carriage of goods between this country and its Colonies. Here, it must be confessed, the State, as represented by the War Office, the Colonial Office, and the Crown Agents, has done less than its duty. Take the classic instance of the South African shipping ring. The creation of monopolies by the State may no doubt be justified in many cases by the end in view; railways, gas and water companies, harbour boards and similar bodies are monopolies created by the State; such bodies are granted certain privileges in return for specified services, but at the same time their powers are carefully and rightly controlled by the State. Why then should not the same control be exercised over such a body as the South African shipping ring or conference, if that name be preferred? It may be said that the conference was not called into being by Act of Parliament. Nevertheless this powerful body, which by its action has done so much to divert British trade in South Africa into foreign hands, was called into life, or rather endowed with its present vitality and power by the action of the British Government. It was the contracts placed in the way of the shipping conference which armed it with powers to oppress the private and especially the smaller trader. Who placed those contracts, but the War Office, the Colonial Office, and the Crown Agents? Was it equitable then to allow this powerful body, armed by the State with a virtual monopoly, to cripple British trade with South Africa by levying carriage rates that were in many instances extortionate? Further, to rivet those rates, so to speak, through the so-called rebate system, which is

nothing more nor less than caution-money levied on shippers to ensure their continued submission to the yoke of the conference? The whole conduct of this ring has been designed to coerce British manufacturers, merchants and shippers, into paying rates, that in many instances made competition hopeless against American goods. The difference of freight to South Africa in favour of the New York shippers has, in many cases, been equal to a working profit on some classes of goods, notably hardware.

The pernicious effect on the expansion of British trade in South Africa of this shipping ring has been fully recognised in the resolutions at the recent conference of South African Governments at Cape Town. Most explicitly was the condemnation passed on the methods of the ring as unjustly favouring foreign shippers and placing small traders at a serious disadvantage as compared with public bodies such as Government departments and powerful shippers in general. The recommendations of this conference are drastic, and would no doubt be calculated, if put into effect, to abate the serious evils against which they are directed. But is it not remarkable that it should have been left to these colonies themselves to denounce officially the excesses of an ill-restrained monopoly which owes its birth to the fostering care of the mother-country! True it is that the home Government was represented at this conference, but the whole movement was essentially colonial, though very likely the agitation set on foot in this country contributed an appreciable share to the result. In considering, however, the true functions of the State as regards the promotion of industrial activity and the expansion of British trade, it is impossible to forget the extraordinary attitude last session of the Colonial Office during the scathing exposure of the shipping ring's methods and policy in the House of Lords by Lord Portsmouth and Earl Grey. The Duke of Marlborough, who represents the Colonial Office in the House of Lords, whitewashed the ring and calmly put aside all suggestions for reform. Yet less than three months later, a conference of all the South African colonies (including Rhodesia) solemnly condemned the system which the Under-Secretary of State for the Colonies had defended in the Imperial Parliament. In some respects, I must say it, our colonial brothers have a truer conception of the duty of the State towards the trading community than exists in this country. Very possibly this feature of colonial life was in the mind of the Prince of Wales when almost in stepping off the good ship *Ophir*, he gave utterance to the words, "Wake up, England!"

British trade with Australia is hampered by being in the hands of a somewhat similarly organised shipping monopoly to that of South Africa. American traders can send their goods to this market at about 12s. 6d. per ton less than we can. Little wonder is it that our trade with this part of the Empire is actually decreasing.

It can hardly be contended that it is not the function of Governments to supervise and control, if need be, the action of trusts and all combinations of this character. That free competition is a better regulator of prices than any Government official is beyond contention, but the essence of a trust is to abolish competition by the creation of a monopoly. Now it cannot too urgently be impressed upon the public conscience, that it is the duty of the State, which is only the guardian of the common weal, to keep a watchful eye on all monopolies, whether created by its own act, either in whole or part, as is the case with a gas company and the shipping ring, or brought into being by the spontaneous action of capitalists, as in the case of the Australian and African meat trusts.

The State as a Lighthouse to Traders.

If there is one point more than another in which the Colonies give the motherland a lead, it is in regard to the fostering care which the State almost invariably extends to industry and commerce. Whoever heard of a British public department troubling its head about the representation of home industry at great international exhibitions? It is true grants are made now and again on such occasions, but only on such a meagre scale as to excite the derision of visitors to the show, thereby defeating their object. Very differently do the Colonies in these matters. Canada has a permanent Exhibition Committee, which consists of experts and linguists capable of effective work in almost any civilised land. The result is that the Dominion is properly and efficiently represented on every suitable occasion. As an instance of the careful attention which the Dominion Government devotes to the expansion of its export trade, it may be mentioned that refrigerator cars are provided on the Canadian Pacific Railway in which farmers and exporters can forward any perishable articles to the seaboard free of any extra charge.

In one respect in particular, the Colonies, one and all, set us an example that might, and indeed must be followed, if we are to keep our position among the great trading nations. There is no self-governing colony which, so far as I am aware, has not an Agent-General in London. Now these officials are very largely ambassadors of commerce; at any rate one of the most important duties attaching to their office is the collection and dissemination at home of information respecting the value of Great Britain as a market for the colony's produce and goods. Again, in South Africa, both Canada and New Zealand have located permanent trade commissioners. These are officials whose duties go beyond the mere transmission of general details concerning trade. They are furnished with offices and staffs capable of acting more or less as travellers for the trade of their colony.

If the Colonies, with their comparatively limited means, can do this useful work for the expansion of their trade, why cannot the British Government with its unequalled resources, give a mighty impetus to the expansion of British trade in the Colonies, and in foreign countries? The word Government is an elastic term. We will see how the State, merely by an intelligent use of its existing machinery, and by the expenditure of less than a tithe of the sum it annually devotes to the Army and Navy, could materially assist in the expansion of British trade throughout the Colonies and the whole world, for that matter. What are the public departments which may fairly be called on to assist in the development and expansion of British export trade? These are, I should say, the Foreign Office, the Colonial Office, and the Board of Trade.

Our Consular Service.

The Foreign Office is already doing, and has long been supposed to do, a certain amount of commercial intelligence work through its consular service. Unfortunately this work is done too often in a perfunctory and slip-shod, because general way. Commercial men who are seeking information respecting foreign markets, want exact news as to prices, freights, the needs and preferences of the district, the nature of the competition likely to be met with, and so on. Such information the typical consul is not able to furnish. To begin with what is a consul? In one of Lever's novels this query was answered by "an official who puts mutinous seamen in gaol." This definition was not quite comprehensive enough even in Lever's day, but it has still a great substratum of truth. It is to be feared that those who contend that the British consular service needs reorganising from one end to another, have a strong case. At the same time reformers of the consular service will have to bear in mind the very multifarious duties the British consul has to discharge, especially in the near and Far East.

If you look over the Foreign Office List you will find, among the names of consuls, and still more of vice-consuls, many with a foreign ring. The bulk of these officials are not British consuls in the proper sense of the word. They are chiefly local men, probably naturalised as British subjects, who discharge the duties of consul, vice-consul, consular agent, or what-not, for a nominal salary, or no salary at all. They are sometimes known as trading consuls; they supplement their salaries or no salaries, by trade, foregoing thereby, if I am not mistaken, any claim to a pension. No doubt most of these trading officials manage to make accounts balance on the right side, but is it reasonable to expect of them whole-hearted service to British trade? The trading consul is, in this age, an anachronism, and must be dispensed with, in any shape or form. Remember that it is on such men that the consul or consul-general has to depend for the substance of his periodical reports on the state of trade in his district. Are consular officials of this type likely to be the most suitable to promote the expansion of British trade?

It may be freely conceded that during the past ten years a great improvement has been effected in our consular reports, and I am afraid that many traders in this country do not sufficiently appreciate them even as they exist to-day. Though too frequently lacking in the precise details which are the breath of true commercial information, they often give particulars respecting local trade customs and the general trend of demand for manufactured articles which should be of some use.

In the main, however, our consular commercial reports do not compare favourably with those published in some other countries. Take the admirable publications of the United States' foreign department. An excellent feature in the commercial information system of the great Republic is the series of monographs periodically published respecting the condition abroad of any particular branch of industry.

I have just perused two such books. Neither is bulky; in each case a demy octavo volume of some 250 pages is packed with information gathered from all points of the compass. One volume is concerned with nuts and bolts, the other with drugs and patent medicines. The latter is a perfect mine of information respecting the laws of all countries, civilised and uncivilised, on the sale of medicine. The drugs most in demand in different lands are all set forth. This book was made up from consular reports, specially called for no doubt; the editing must have been a considerable work in itself, but the book contains information which no single firm could have gathered except at a prohibitive cost; even then the work would have occupied years to compile. We have no such publications in this country.

Another consular service which is admirably organised for the dissemination of commercial intelligence is the Austro-Hungarian. In the reports published may be found terse but lucid summaries of what lines of goods are in demand in particular markets; the qualities called for are always carefully distinguished, while some idea of ruling freights is given. The competition that may be expected from other lands is almost always laid out. More helpful guides to the export trade of the Austro-Hungarian Empire can hardly be imagined.

But while it is certain that our consular reports are very far from what they should be, and from what they must be made, no one who has had any experience of export work would be content with the collection of news solely through this source. Yet the Foreign Office could render great service in the direction indicated. To enter, however, into the larger question of how far it is desirable to convert our ambassadors into ambassadors of commerce when railways and great public works are in the air would perhaps be going too far on this occasion. Yet unless rumour is more than usually at fault, the German and Russian Ambassadors at Constantinople are as much concerned with the advancement of commercial as of political schemes; it has been credibly asserted that German consuls in the Levant act as efficient enquiry agents for German traders who are asked for credit by native dealers.

The Board of Trade.

The co-operation of the Colonial as well as of the Foreign Office should be enlisted in the cause of our export trade. But the public department which should serve to focus, as it were, all commercial information collected for the use of our export trade, and should act as the motive spring of our commercial news service, is the Board of Trade. There is something in a name after all, and such a title should stimulate the department that bears it to some serious effort on behalf of the trade of this country. The history of this department is typical of the growth of British institutions. The department dates from 1786; a mere enumeration of the designated members of the Board is a sufficient indication of the hazy conception of its task which the new department had to face. Among the original members were the Archbishop of Canterbury, the First Lord of the Treasury, the First Lord of the Admiralty, the Speaker of the House of Commons, and many other strangely assorted dignitaries. To this Board was to be referred "all matters relating to trade and foreign plantations." There is no record of the deliberations of this body, if ever it met. For one thing, the "plantations," or, at any rate, a goodly part of them, were careful to look after their own interests, and are known to-day as the United States. But the Board of Trade lived on, and as steam brought into being railways and steamships, some useful work was found for this department. It was however mainly of the policing order. To this day the greatest activity of the Board is displayed in the inspection of new rail and tramway tracks, in prosecuting shipowners who overload their vessels, in fining the owners of corroded boilers (when they explode), and in looking after weights and measures and bringing bankrupts to book. But under the pressure of public opinion the department has moved some way in the past quarter of a century. True the progress was slow. Long after the introduction of gas the then offices of this department were lighted by dimly flickering candles. Nowadays great improvements have been made in the plant and general equipment. The department is on the telephone, though it seems to need a great deal of "calling up." Whether the transformation of this Board into a Ministry of Commerce and Industry is desirable is perhaps for our purpose rather beside the mark. What it is well to bear in mind is the fact that already the Board of Trade have been furnished with a new limb. It was in May, 1900, that a commercial intelligence department was founded, and an advisory committee, consisting of eminent men, appointed to direct its work. But as ordnance

cannot be worked without powder, neither can the central commercial intelligence department of the British Empire accomplish much useful work on a grant in aid of £1,000 per annum, even when allotted for "five years certain." With these small means the advisory committee has already managed to do some good work, in South Africa, Persia, and Siberia, but to make this innovation more than a mere farce, £20,000 per annum at least must be expended.

TRADE COMMISSIONERS WANTED.

The true function of the Board of Trade, or whatever title this department may take, is to serve as a lighthouse or beacon to the traders of the whole British Empire. It should be the means of stimulating to useful work in the collection of commercial information the officials of such departments as the Indian Office, the Foreign Office, and the Colonial Office.

Over and above the work done by the Foreign Office staff, under the superintendence of the Board of Trade, special trade commissioners should be appointed by this department to reside in British self-governing colonies or in any land that may hold out special outlets for British export trade. Such commissioners should be men of commercial knowledge, and, if possible, trade experience. They should have some knowledge of modern engineering, because the development of our colonies is largely a matter of engineering. They should be instructed to keep themselves informed of all trade movements in their respective territories by constantly travelling about. They must also be furnished with an efficient staff of local correspondents; because our colonies—South Africa, for instance—are big, if sparsely populated countries. They should be capable of reporting fully on any business that may be going, and be instructed to use the cable in all cases of urgency. The important point is this, that the information, whether or however published, must be accessible to the smallest as well as to the largest firm in Great Britain. This is the worthy and indeed only course for a democratic State to pursue.

"Information and more information" is the cry of the manufacturer and trader of Great Britain. Comparatively few firms can afford to specially investigate the possibilities and peculiar needs of foreign markets at their own expense. There are hundreds of manufacturers now confining their attention almost solely to the home trade, who would soon develop an export business if such information as I have indicated were made accessible to them.

WHAT THE BRITISH MANUFACTURER HAS GOT TO DO.

I think I have given some idea of the cooperation which the State may be fairly asked to, and indeed must give, if this great industrial country is to hold its own in the struggle for the world's export trade. But the duty of the industrial community in this land, or rather of its chiefs, whether they employ one hundred or thousands of hands, is not less clear. They must, in the first place, keep on "ringing up" thepublic departments. The Government official is by training an unprogressive creature. Change is uncongenial to him. He lives, to a certain extent, in an unreal world. If the history of almost any reform or innovation in the public service were written, it would be found to have originated either in some irresistible clamour of public opinion, or more rarely in the bold initiation of some strong minister, who, seeing existing practice to be at fault, resolved to mend it in spite of all bureaucratic opposition. But it takes a very strong man to break through official tradition, and such ministers are born, like great generals, perhaps once in a century. On the other hand, public opinion, when once set in motion, is irresistible. True it is that such a consensus of opinion is very hard to organise, especially in questions of trade. Trade is a subject not always calculated to excite the wildest enthusiasm, but British men of business must remember that their interests are in this matter of colonial and foreign trade vitally touched. If they bring their full force to bear on the Government departments these offices will promptly yield.

THROUGH BOOKINGS WANTED.

The main point which the British manufacturer has carefully to keep in view is the absolute necessity of getting into immediate touch with his market whether it be in a British colony or a foreign land. The importance of this may be easily overlooked. It must be borne in mind that our most dangerous competitors in many colonial and foreign markets are the United States and Germany. How wantonly South African trade has been driven, so to speak, into American channels has

already been pointed out, but it would not do to overlook the fact that both of our great competitors have for some time adopted more scientific methods in pushing their trade abroad. In other words, by means of through bookings they have managed to get into direct touch with the foreign customer. Though the German merchant may not be able to get a better sea freight than his British competitor, he has this advantage over him, that the railways in his own land, which are all more or less under the control of the State, will quote him a better through rate to the port of shipment than the British manufacturer can usually obtain.

Transport is, after all, an item as essential to the cost of an article as labour or any other factor in the manufacturer's bill of costs. The shipper who can quote his oversea customer, the exact or even fairly approximate cost of delivery, is in a much better position than the man who is encumbered with forwarding agents, and is working, to a great extent, in the dark.

I am glad to say that in one direction a great step forward has already been taken. The Post Office, after a good deal of spurring on by British traders, has at length consented to institute the C.O.D. system with all British colonies. For many years it is understood, this system has been worked by the German Post Office, and with good results. The system is simplicity itself. A lady in Melbourne, for example, may take a fancy to a set of fish knives, as shown in an illustrated catalogue, dispatched from Sheffield. She has only to send a penny post card to the works in Sheffield, whereupon a neat package can be made up in a few minutes and committed to the care of the post, the ordinary parcels charge being of course paid by the sender. But there his work is done. The post delivers the knives and collects the money, without which of course the postman would not give up possession. The sender is freed from all trouble and expense or enquiries, which in a matter of this kind would simply stop business altogether. On the other hand what an extension of British trade with the Colonies may be promoted by this judicious step. Though it may be true that the best results cannot in many cases be attained by those who seek an oversea trade, even with British colonies, unless good travellers are employed, yet a great deal can be done by going directly to the consumer.

National Engineering and Trade Lectures.

I have already spoken of the importance of the State undertaking the supply of commercial information to the British manufacturer and trader as to the needs and capacities of markets, and I would also point out that it is almost equally important that we should make known to buyers all over the world what we have to sell and are capable of producing. When touring through America, and later on going through South Africa at the close of the war, I was astounded at the ignorance which prevailed in those countries as to the progress Great Britain has made in recent years in her manufactures and processes. So much has been said and written of the conservatism of British traders, the antiquated methods and obsolete machinery in our workshops, and so many alarmists' statements concerning the decadence of our industries have been made that our Colonies and foreign countries have been seriously impressed. We cannot deny that a few years ago we were, in many respects, behind the times and badly needed waking up. Hitherto our manufacturers have relied chiefly on the qualities of durability and excellence of workmanship to recommend their goods to buyers in markets outside of Great Britain. This was very good in its way until the pushful American came along with his low-priced article, his attractively designed advertisements and aggressive business methods. Something more is now needed. Great Britain has effected enormous improvements in her manufacturing and industrial methods in the last few years. New works have everywhere been laid out and old ones remodelled, with a view to economical manufacture and the easy handling of material. Huge quantities of obsolete machinery have been consigned to the scrap heap and replaced with those of modern design, and everywhere British firms have laid and are laying themselves out for the manufacture of machinery and goods in quantity and on standardised and specialised lines. When the British manufacturer made up his mind that something was wrong he did not lose much time—with a silent celerity, he has been engaged in pulling down and building up with that quiet determination to lead that never yet failed his countrymen.

It has impressed itself on my mind that these are facts which should be made known to the world in some special way. The means to wide publicity at the disposal of individual firms is necessarily limited. They can, of

course, advertise in journals, and in ordinary ways, and distribute catalogues broadcast, but it seems to me that something more is needed—something in the nature of a national vindication of the character of the British manufacturer and trader. And it was with this idea in my mind that I have devoted a great part of the past two years to the development of a plan for giving the world a true conception of British manufacturing and industrial progress.

In a few words, this plan is that lectures be prepared by the leading experts in various branches of engineering and manufacture, for reading before Chambers of Commerce, technical institutions, colleges and schools in colonial and foreign industrial centres, emphasising the progress made by Great Britain in the manufacture of all the classes of goods and machinery, and their novel points of design and utility. It will be a special feature that each lecture will be illustrated with lantern slide views, thus depicting the interesting points in the most graphic manner. This enterprise has been made possible by the generous co-operation of a number of the most eminent engineers and specialists in Great Britain, and I desire to take this opportunity of expressing my appreciation of their hearty co-operation with me in this work. We want to show to our colonial brethren that as a scientific manufacturer, the Mother Country is second to no country; that if some rivals have excelled in modern works and improved machinery, they will in turn excel with works still more modern and machinery still more improved.

I am glad to say that our Government departments have given this scheme their assistance, while the Agents-General of our colonies have, without exception, co-operated with me in arranging that lectures should be reproduced and delivered before audiences that will appreciate them in one and all of our colonies. Regarding these lectures as a means of educating manufacturers and engineers, the leading foreign Governments are facilitating their delivery in their principal industrial centres, and in several instances are introducing them into their schools.

In the course of the next twelve months the story of British manufacturing and industrial progress will be told to hundreds of audiences in colonial and foreign markets, and if its telling helps to maintain and expand British trade, the efforts of myself and colleagues will have been amply rewarded.

[A number of lantern slides, illustrating the subjects of some of the lectures referred to, were shown on the screen after the reading of the paper.]

DISCUSSION.

Mr. JOHN SAMSON said he was not competent to speak upon the question of trade with the colonies because he was connected solely with South America, in regard to which country he could speak with a considerable amount of experience. The author had started with a very commonly accepted theory, namely, that British manufacturers were anxious to do business. His experience was completely to the contrary. British manufacturers appeared to be absolutely indifferent as to whether they did business or not. He was director of a company which was engaged in extending trade in South America, and he was continually sending out letters to manufacturers offering business, and in many instances he had never even obtained a reply. If, on the contrary, he sent letters to continental houses he invariably received carefully prepared estimates. When people found themselves better served by foreign manufacturers than by English manufacturers they would go to the former. He alluded especially to rails and railway plant. He was told by an engineer in a very large way of business that he considered it a waste of time to ask for estimates in England; the manufacturers either took a very long time to answer, or quoted prices which were absolutely impossible. In the second place he found that very few English manufacturers sent out their catalogues in foreign languages, and in the country he was connected with, catalogues, in English only, were absolutely useless to his clients. The author had spoken of through bookings. It was almost impossible to get any English manufacturer to quote for free on board to so near a place as Antwerp, although they would quote free on board for Glasgow, Liverpool, or London. All these things went to show that manufacturers in this country were not keeping place with their rivals. The author said that the Government ought to do more to provide commercial intelligence. About the year 1898 Mr. Chamberlain took that line, and appointed a Commissioner to go to South America; he also asked a Chamber of Commerce to appoint another member to represent them, and it was very significant that the Chamber of Commerce declined to appoint any such representative, and, therefore, the Board of Trade representative went alone. The author made a point in saying that the Board of Trade and the Commercial Department of the Foreign Office did not provide commercial intelligence for the use of manufacturers, but he held that the Board of Trade and the Commercial Department of the Foreign Office did provide more commercial intelligence than there was demand for. Tenders were asked for particular goods and no answers were received.

The Commissioner sent to South America by the Board of Trade sent home a very long and detailed report, which he questioned if any manufacturer had ever read, or even asked for. It was true that consular reports were imperfect and published very late, but the experience of the publishers was that they had no circulation at all, except amongst journalists. At present the reports could not be sold in Leeds. The Commissioner also brought home with him a very large collection of samples, and it was announced in the newspapers that those samples were to be exhibited at the London Chamber of Commerce and at Whitehall; the samples were on exhibition for about twenty days, and only about twenty persons had signed the attendance-book when he visited the exhibition. If he went to a manufacturer and said he could give him information which would be of value to him, he was asked to state his business, and in most cases the manufacturers did not care to give an audience at all. Therefore he held that if England was losing her colonial trade it was because her rivals were doing better, and England deserved to lose her trade under those circumstances. The first thing to be done was to awaken anxiety amongst British manufacturers to get that information, because the remedy proposed by the author would be of no effect until British manufacturers were educated to take an interest in their business.

Mr. E. T. SCAMMELL agreed with the last speaker, that the British manufacturer needed waking up, and that no talk about fiscal or any other reform would take the place of the awakening which was essential if England was to hold her own in the march of the world. He knew something of the Australian colonies; and the merchants and manufacturers of this country did not appear to be willing to learn the lessons which were taught them both by Germans and Americans in regard to many of their business methods. If somethiug could be done in this country thoroughly to arouse the attention of manufacturers on the point, the business done not only with the Colonies, but with the world at large would be greatly increased. He was glad to hear that steps were being taken for the spreading of further information. The last speaker had a little misunderstood the author's plan, which was not so much the giving of information to the manufacturers in this country as the spreading of the information in the Colonies. But he thought the Government might do more in this country. Those who were present when Sir William Abney gave his address on the previous Wednesday, heard one or two most important particulars in reference to which the Government might aid the commercial and industrial enterprises of the nation. If lectures were given in the Colonies, it would help to remove the misapprehension that prevailed, that the British manufacturer was fast asleep, and British commerce would thereby benefit.

Mr. SAMUEL CHAPMAN stated that he had lived in the southern part of Mexico for a number of years, and had noticed that when opportunities were offered to British manufacturers, they did not always avail themselves of them. English trade had increased in Mexico in the last ten years by 74 per cent., while German trade increased during the same time 225 per cent. He remembered, on one occasion, a firm who desired to place a large order for sugar machinery with an English firm, but so much difficulty was experienced in getting anything like a favourable quotation that eventually the order went to Belgium, solely because the quotations given were not suitable for a country speaking a different language. On the other hand, a large Lancashire firm sent out a representative about nine years ago to fit up some machinery. It was expected that he would be away four months, but he had never been over to England during the nine years that had elapsed, having been constantly filled with orders during the whole time. That was an instance of what British manufacturers could do if they would only take the proper steps. It was not only a question of the language, but also of following the instructions of the purchaser. Instead of china, for instance, being packed as specified, in a particular case, it was packed in such a manner that when it was landed considerable damage was done to the consignment, with the result that no further business had been done between important firms in the South of Mexico and china makers in this country. Too little attention was paid in this country to educating young men in foreign languages; and it was also very desirable that manufacturers should be acquainted with the metric system, so as to use it alongside the present system, even although the metric system might not be adopted by the country.

Mr. WALTER REID adversely criticised the lantern slides which had been shown by the author, saying they were by no means up-to-date. If the saloon car shown were put side by side with some of the Pullman cars turned out in large numbers in the United States it could not possibly hold its own. A better illustration of the turbine steamers would have been one of the new boats being built by the Cunard Company, of which there was a beautiful model in the St. Louis Exhibition. The Forth Bridge was hardly a thing to show to people who must become customers, because there was only one such bridge in existance, and each engineer built his own bridge according to his own designs; a better illustration would have been the factory in which the steel was turned out to make the Forth bridge. Dynamos like those shown on the screen could be picked up on scrap-heaps in the United States. He was sorry to hear the author say that high-speed cylinder engines also represented the best practice nowadays, because hardly a dynamo now made in America could be found running with reciprocating engines; they were all turbines. The whole of the electricity at the St.

Louis Exhibition was produced by means of turbine engines, and no American engineer would dream of putting up large reciprocating engines nowadays for the production of electricity. He could not impress too strongly on the author, whose scheme of giving lectures he approved, that he should be extremely careful in the selection of the slides, otherwise they must do more harm than good. With regard to the action of the State in such matters, there was no doubt the Government could do a very great deal more than it did. One of the reasons why State inference had been less productive of good in Great Britain than in Germany and France was that the State in England did not consult the different classes of producers to the extent the State did, especially in Germany. Before the German Government undertook any legislation of an industrial character, it consulted the representatives of the Trade Guilds, and unless our Government did something of the kind, any steps taken must prove injurious rather than beneficial to the trading community.

Mr. W. RAVENSCROFT BETTELEY thought the author bit the nail on the head when he asserted that the manufacturer should place himself in touch with the dealer. He had had an experience of forty years as a merchant in South America. The majority of the catalogues which manufacturers sent to that country were put into the waste paper basket, because they were printed in the English language. If the English manufacturer would take the trouble his German, French and Spanish competitors took, and have the catalogue translated into the language of the country, his trade would largely increase. If an English manufacturer could not send out a competens traveller, his best plan was to appoint a good firm in the country, in touch with the people, as his agent, who would then obtain the necessary business. He was sorry to say that the English manufacturer was losing his trade in South America. Forty years ago it was an exceptional thing to see a German in Buenos Ayres, but to-day Germans were in the majority, simply because of the better business methods employed by them. If some means could be found to arouse the British manufacturer he might fill the important place he ought to occupy.

Mr. C. ALFRED SMITH thought that Mr. Reid was rather unfair in his criticism of the lantern slides. He had made the sweeping statement that the whole of the current generated at the St. Louis Exhibition was produced by means of steam turbines. He had been told by a gentleman who had visited the place that, although as in England, the steam turbine was going ahead for central station work, that statement was not correct. It was only within comparatively recent years that the turbine had been recognised as a success, and the reciprocating high speed engine, although it was being strongly competed with, was still in the front rank as an electrical generator. A great deal of discussion had taken place with regard to technical education, but only one university had taken the trouble to found a faculty of commerce, viz , Birmingham, at the initiative of Mr. Chamberlain. Hundreds of students went through engineering courses who were altogether unsuited by temperament to become expert engineers, but they would make fine agents, and it was sad to think that in almost all the colleges the students had no opportunities for learning the commercial side. The advantage of students learning foreign languages was not impressed upon them, and he thought something might be done by the Society of Arts in enforcing that need on the younger generation. The hope of the country laid largely with the coming generation, and if some of the energy that had been put in the last few years into the evening technical classes could be put into the University colleges, he believed the trade of the country would be greatly benefited.

The CHAIRMAN, in proposing a cordial vote of thanks to the author for his extremely valuable paper, said that in following the author's statements he noticed that the lectures were not only to be given for commercial purposes to commercial men, but were to be given for educational purposes to schools, and in that case it was well to show the progress that had been made by means of lantern slides, although of course those slides must be absolutely up to date. One of the opening sentences in the paper had particularly struck him, because it opened up a vista of the loss sustained when any considerable diversion of colonial trade, which naturally belonged to English manufacturers, took place. Any trade which could be legitimately carried on in this country and went from the Colonies to foreign countries was necessarily attended by a gradual estrangement from the Mother Country. Correspondence followed commercial relations; one of the partners of the firm paid a visit to the country with which the business was done; he formed relationships of all sorts, and it was almost impossible to say where the evil ended when once a diversion took place, from the natural channels of trade that ought to take place between the Colonies and the Mother Country.

The resolution of thanks to the author was then put, and carried unanimously.

Mr. WALTER REID said his statement that the whole of the current generated at the St. Louis Exhibition was produced by means of steam turbines, had been called in question by Mr. Smith. He had papers in his possession which proved that practically the whole of the current was generated by steam turbines, and he did not wish Mr. Smith' statement to go forth to the world uncontradicted.

Mr. MORGAN, in reply, said that the reciprocating engine was still in the front for powers up to 200 horse-power, turbines not being economical engines in small powers, except in one or two instances. The engines referred to by Mr. Reid were large ones of 500 horse-power and over. The engines he showed on the screen were only for very small powers. With regard to the up-to-dateness of the pictures, he thought they should be content to leave the selection of them to the lecturers, who were amongst the most eminent engineers and specialists in Great Britain, and included Sir William Preece and Mr. Swinburne, both of whom were past Presidents of the Institution of Electrical Engineers.

MISCELLANEOUS.

THE WORLD'S COTTON SUPPLY.

Nearly a hundred and fifty years ago the Society of Arts was moved to use its influence to encourage the growth of cotton within the Empire. In 1761, as now, "the scarcity and consequential high price of cotton was a great detriment to our manufactures," and the Society had seen specimens of cotton from Senagambia, which led it to believe that an adequate supply could be obtained from Africa. "The Society was informed this cotton could be collected in any quantities whatever, at a low price, perhaps not exceeding a penny per pound," and it was of the opinion that it was a matter of national moment to encourage the growth of cotton in the African colonies, and elsewhere within the Empire, therefore the Society offered (in 1760) the following premiums:—

"For the greatest quantity of clean merchantable cotton; the growth of any of His Majesty's settlements on the coast of Africa, imported by private adventurers into any of the ports of Great Britain in the year 1761, not less than two tons, a gold medal.

"For the second greatest quantity, not less than five tons, a silver medal.

"And the like premiums, on the same conditions, will be given in the year 1769."*

Now, under very different conditions, we have a recurrence of the scarcity. The supply has not kept pace with the demand. It is true there has been a very large increase in the production of cotton in the United States during the last 30 years. In 1875 the total American production was 4,632,313 bales, it now exceeds eleven million bales, but the exports have not, proportionately, increased. Of the 4,632,313 bales produced in 1875, 2,982,810 was exported, 1,649,503 sufficing to meet home requirements, whereas last year the home consumption had increased in round figures to 4,000,000 bales, and will, no doubt, go on increasing. When we turn to other sources of supply than American, we find exports practically stationary. Thus in the decades 1870-80, 1880-90, and 1890-1900, India produced an average of two, two-and-a-half, and two million bales, whilst her own requirements steadily, though not very rapidly, increased. In Egypt the production nearly doubled in the 30 years from 384,000 bales to 700,000, but Egypt only supplies a small proportion of the world's production, and Brazil, the only other considerable producer of cotton, fell away from 600,000 bales to 380,000 in the same period. Thus the world is as dependent to-day upon the United States for its cotton supplies as it was 30 years ago, whilst the European demand has enormously increased. In the seventies England took the bulk of American cotton. To day continental spinners take a third of the whole of the American cotton. Comparing the year ended 30th June, 1889, with the year ended 30th June, 1899, we find that the exports of cotton from the United States to Germany increased from 660,756 bales to 1,728,975 bales; to Austria-Hungary from 5,610 bales to 57,127; to France from 400,196 to 803,406; to Italy from 131,068 to 417,353; to Spain from 181,533 to 248,635; whilst the exports to the United Kingdom only grew from 2,940,800 to 3,609,444. And year by year the continental demand diverts a larger proportion of the American product from England.

It is impossible to exaggerate the gravity of the outlook as it affects this country. Great Britain is practically at the mercy of the United States, and the sufferings of industrial Lancashire during the American Civil War give us an inkling of what that may mean. Already, Lancashire has suffered seriously from the growth of the continental demand, coupled with the rapidly growing requirements of the American home market. In 1901 and 1902, many of our cotton mills were unable to run full time owing to the shortage of cotton. In 1903, most of the Lancashire mills ran short time for four months, and a conservative estimate puts the direct loss suffered last year by the spinners, manufacturers, and operators at £2,000,000, which takes no account of the losses consequently entailed upon merchants and others indirectly interested in the cotton trade. This year, most of the Lancashire mills have been compelled to run short time for eight months, which means immense loss in the productive and earning power of the most important of our manufacturing industries. How great it is may be understood when we say that an authoritative estimate of the loss that would be incurred if all the cotton mills of this country were running three-quarters time instead of full time, puts it at £300,000 a week, or at the rate of £15,000,000 per annum. No fewer than 10,000,000 of the population of the United Kingdom are, directly or indirectly, interested in the cotton industry; and it may be taken as certain that much of the general

* These particulars are taken from Dossie's "Memoirs of Agriculture," vol. 1, page 302.

stagnation of trade is due to shortage in recent years of the supplies of American cotton.

Those most directly interested in lessening our dependence upon America have been rather slow to move, but a beginning was made at Manchester on May 8th, 1902, when a meeting was held at the Albion Hotel in that city, under the auspices of Mr. Arthur Hutton, the President of the Manchester Chamber of Commerce. The Chambers of Commerce of London, Liverpool, and Oldham were represented at the meeting, together with the managing director of the British West African Steamship Line, Sir Alfred Jones, the Oldham Cottton Spinners' Association, the Manchester Cotton Spinners' Association, various other Associations of a similar character, from Blackburn and other Lancashire towns, cotton machinists, brokers, weavers, and manufacturers. The object of the meeting was to widen the area of cotton cultivation under the British flag, more especially in West Africa; and before the close of the proceedings a British Cotton Growing Association was formed, with a preliminary capital of £10,000 to be exclusively devoted to experimenting in West Africa and other over-sea provinces. This meeting was followed by another, held in Manchester in June, 1902, when it was decided to raise a guarantee fund of £50,000, to be spread over five years, and inquiries were commenced throughout those portions of the British Empire where the conditions as to possibilities of cotton growing are suitable. Experimental plantations were inaugurated, large quantities of seed were distributed, ginning and baling machinery was sent out, advances were made to planters, and grants were made to various colonies. But £50,000 was very insufficient if the intentions of the Association were to be carried into effect, and so we find it in October, 1903, making arrangements to increase the guarantee fund to £100,000. It was, however, soon seen and admitted that even this larger sum was very inadequate to the requirements of the Association, and it was decided to increase the fund to £500,000, and to petition the King to grant a Royal Charter of Incorporation to the Association. In August last this charter was granted and the British Cotton Growing Association was thereby incorporated. The Association is already actively at work in various parts of the Empire, and the Government are cordially co-operating in the work. An arrangement has been entered into with the Secretary of State for the Colonies whereby in consideration of the work that is being carried on by the Association the Governments of Lagos, Northern Nigeria, and Sierra Leone will, during the ensuing three years, make grants to the Association amounting to £6,500 per annum. Several of the large steamship companies, too, are at present lending their assistance towards the extension of cotton cultivation by carrying freight free or at nominal rates. The Association is now seeking to raise the balance of its share capital. Of the £500,000, £125,332 has already been applied for and allotted, and it is expected that the public will find the balance required. It is not an ordinary investment to which the public are invited to subscribe for the Association may not declare any dividend, or distribute any profits before the expiration of seven years from the date of the Charter, and, in the meantime, any profits are to be applied in the furtherance and extension of the objects of the Association. It is in every sense a national undertaking deserving the support of all interested in the welfare of the United Kingdom.

The capability of the world to provide in sufficient abundance the raw material required by the vast and ever-increasing cotton industry is unquestionable, and cotton of the best quality can be got outside America. What is now known as Sea Island cotton is a native of Honduras. It spread thence to the West Indies, and was carried to the United States shortly after the Revolution. No finer cotton has ever been grown than that raised in the island of Tobago, between the years 1789 and 1792, upon the estate of Mr. Robley; and Egypt has furnished a staple which for quality and length holds a high rank, and comes next to Sea Island. It is not, perhaps, too much to say that Egypt is the finest cotton-growing country in the world, unsurpassed in productiveness even by the United States of America. In South America the cotton plant thrives in all the varied climates from Para in the North down to Rio Grande in the South. In India the quantity available for export can be increased, and although India does not grow the highest quality, the addition will help to lessen the dependence upon America. As for West Africa it is capable of producing more than the present world's supply. Already the cotton industry plays an important part in the prosperity of Kano and Northern Nigeria generally. The cotton plant is met with in a wild state all over West Africa, and the pagan tribes of Sierra Leone, the Gold Coast, and Liberia turn out the most beautiful cloths. Mr. Hutton expects that in the next five years we shall get a million bales from West Africa. From Lagos, it is estimated that from 6,000 to 10,000 bales will be obtained next year, as compared with 2,000 bales last year, whilst in East Africa the outlook is very promising. In Nyassaland alone, considerable quantities of cotton, equal to "Good Fair" Egyptian, can be produced, and should the steps that are being taken to establish cotton growing as a native industry prove successful, then larger results will be obtained. So with the West Indies and British Guiana, advances have been made by the Association to cotton growers, and seed, machines, and implements supplied. The finest qualities of cotton have been obtained from the Sea Island seed, and the industry is now in many districts established on a commercial basis.

The difficulty is not in the growing of cotton, but in its profitable cultivation. The four things requisite for successful cultivation are (1) a suitable soil; (2)

a regularly recurring rainfall and adequate irrigation; (3) sufficient labour; (4) transport facilities. Lack of labour and cheap transport are the chief difficulties, and at present, and in some countries, they are insuperable. And of course much depends upon the price. The German experiments at Togo are very encouraging. There the one thing necessary to complete financial success is adequate transport facilities. The use of improved implements, the introduction of better methods of cultivation, and a more economical system of labour have lessened the cost of cotton production, and having regard to the many countries that may be expected under the present more favourable circumstances to contribute to the cotton supply of the world, it is reasonable to assume that the cotton industry will soon be on a sounder footing than it can ever be under present conditions. The work of the British Cotton Growing Association bids fair to have a great and beneficial influence in rescuing us from our perilous dependence on America, and so deserves the good wishes, and national support, of all sections of the community.

Since the above article was in type, the Paris correspondent of the *Times*, under date November 21, has sent the following important statement to his journal:—

M. Méline, the ex-Premier, makes an interesting contribution to the pressing problem of the emancipation of European industry from the American cotton monopoly in to-day's issue of the *République Française*, taking as his text the incorporation of the British Cotton Growing Association. He represents the cultivation of cotton in the French and English colonies as being the sole means of averting a repetition of the recent threat of a cotton famine, which disturbed the entire industry throughout Europe, and of meeting the approaching peril arising from the steadily increasing absorption of the cotton supply by the growing industry of the United States. If America be allowed to retain her present monopoly of the raw material, M. Méline does not see how she can be prevented one day from exporting it all in the form of manufactured articles. On that day the European cotton industry would have ceased to exist. It is indispensable to lose no time if this peril is to be averted. The effort made by Europe will only begin to be felt when a quantity of cotton is put upon the market sufficient to inspire the American producers with respect.

M. Méline considers that at the present time, the main requirement is capital. He strongly urges his countrymen to follow the English example, characterising the liberal support given by Manchester to the British Cotton Growing Association, as evidence of the traditional energy and broad-mindedness of the English man of business. M. Méline anticipates that in a few years the practical and energetic English will have established the cultivation of cotton in their colonies, and will be the first to compete with the American product in the international market. They will thus be the first to secure custom, so that the French will find the place occupied when they are in a position to compete. M. Méline, therefore, regards the question as one of colonial rather than industrial interest, seeing that in a couple of years French manufacturers will have new English or German sources of supply. In conclusion, he expresses the hope that the matter will be taken up by the French Government.

BANANA AND PLAINTAIN.

In connection with the subject of Barbados bananas, referred to on p. 885, vol. lii. of the *Journal*, Nov. 11, 1904, where it was shown that the variety of banana cultivated in the island is the same as that grown in the Canary Islands and Madeira, a question has arisen as to the distinction between the banana and the plantain. Each has been described under distinct scientific names, the banana as *Musa sapientum*, and the plaintain as *Musa paradisiaca*, but botanists have long been agreed that there are but few, if any, distinctive characters by which they can be separated, and that the plantain is simply a variety of the banana, and classifying it as *Musa sapientum* var. *paradisiaca*. At one time, the fruits of the banana were described as being shorter and rounder than those of the plantain, but with the extended cultivation of both, even these characters are not perceptible. The greatest distinction, perhaps, is in the edible qualities of the fruits, the banana being of a more delicate flavour. As a proof of the unity of opinion of the older botanists with those of the present day, it may be said that Roxburgh believed *M. sapientum* to include both the edible fruit known as banana, and the vegetable-like fruit known as plantain, both of which he considered cultivated forms or varieties of the same species.

With regard to the economic side of the question the "Dictionary of the Economic Products of India" further proves the difficulty of fixing a line between the two in the following paragraph: "The fruit of the cultivated forms of this species [*M. sapientum*] are sometimes popularly distinguished by the names of banana and plantain, according to whether they are eaten raw or cooked. These names are, however, very loosely applied, some calling any round and plump fruit 'banana,' others making a distinction in size only, the small being 'banana' the large 'plantain.' It is, therefore, advisable to reject the arbitrary distinction which has arisen between the names, and to call all alike by the commoner name plantain." This may be conveninent in India and other countries, where plantains are generally used as a vegetable, but the name banana, for the edible fruits, has now become so firmly established in England that it cannot well be changed.

LANTERN LECTURES ON THE UNITED KINGDOM FOR USE IN THE COLONIES.

The following memorandum has been issued by the Colonial Office :—

The object of giving to the school children of the United Kingdom better knowledge of the Colonies, and of giving to the school children of each colony better knowledge of the United Kingdom and of other parts of the Empire, has been brought into prominence by various organisations, and commended itself to Mr. Chamberlain when Secretary of State for the Colonies and to Mr. Lyttelton, the present Secretary of State.

With their approval a small Committee has been formed to carry out a suggestion made in the first instance to the Colonial Office by Mr. M. E. Sadler while at the Board of Education, that very first-rate lessons or lectures, to be illustrated by equally good lantern slides should, on the lines which have been successfully followed out in the United States, be drawn up and used in the Schools of the Empire.

The Committee thought that it would be well to begin on a small scale and in a very modest way, but bearing constantly in mind that if the experiment is to succeed, the letterpress and the illustrations must be the best possible.

Accordingly, acting under the Secretary of State's authority, they drew up a syllabus of seven lectures on the United Kingdom,* each to be illustrated by some forty lantern slides, the subject of the lectures being

(1) The journey from the East to London.
(2) London the Imperial City.
(3) Scenery of the United Kingdom.
(4) Historic centres and their influence on national life.
(5) Country life and the smaller towns.
(6) Great towns, the Industries, and Commerce.
(7) Defences of the Empire.

This syllabus, designed for use primarily in the Eastern Colonies, was sent out to the Governments of the three colonies of Ceylon, the Straits Settlements, and Hongkong, and each colony was asked and consented to give a grant of £300 to cover the expenses of the scheme.

The money being available, Mr. Lyttelton consented to the Committee's request that Mr. H. J. Mackinder, Director of the London School of Economics and Political Science, should be asked to undertake the preparation of the lectures and the general superintendence of the scheme.

Mr. Mackinder accepted the invitation and the lectures will be, in the first instance, delivered in a London Training College for Elementary Teachers. They will be reported verbatim, put into print, and be corrected and edited by the lecturer, the whole, with any special slides which may be designed for the purpose, becoming the property of the three Colonies concerned, but being available for sale to other Colonial Governments.

* Miscellaneous No. 157.

It will be borne in mind that

(1) The lectures are intended for the higher classes in Elementary Schools, or with modifications for adults.
(2) Each lecture may well supply several hours' lessons, being intended to be the text for teaching and a guide as to the method of teaching, and not simply to be repeated word for word in a single hour.
(3) The object is to give to children through their eyes as well as their ears a true and simple impression of what the United Kingdom and its people are like, to explain to children living in the tropics what the seasons mean in this country, and so forth.
(4) The lessons may well be translated into the vernacular languages for use by native teachers.

The Eastern Colonies will also supply material for similar lectures upon them to be used in this country.

Mr. Mackinder has been asked, and has consented to give in December next a lecture, at a place and time to be fixed,* in which he will give an account of the scheme, and at which some of the slides which have been prepared to illustrate it will be exhibited; it is hoped that those who are interested in promoting mutual knowledge of the various parts of the Empire will be present.

TESTS OF NATIONAL PROGRESS.†

In a paper read at Southport, Mr. A. L. Bowley suggested tests by which the national progress in economic well-being might be measured over any defined period. The necessary statistics covering the forty years from 1860 are now offered. The test measurements are of wages, employment, income, prices, and consumption. An index number is formed for average wages, allowing for irregularity of work. A new estimate is made for income, subject to income-tax, allowing for all the changes in methods of assessment, and including estimates for income unduly escaping tax; and a special method is employed for dealing with the changes in the exemption limit. An index number is then formed for average income. The two series of index numbers, for wages and income, are found to have very many points of resemblance; both show a rapid rise from 1860 to 1874, a fall to 1878, two fluctuations to 1893, and a rapid rise to 1900. The series are then combined, and allowance is made for the fluctuations of prices; the resulting index number shows a nearly regular progress throughout the forty years. The index number for consumption of common necessaries also shows fairly regular pro-

* It has now been arranged that the lecture shall be given at the Whitehall Rooms, Hotel Metropole, on Wednesday, 7th December, at 5.0 p.m. The Secretary of State has consented to preside.

† Abstract of paper read by A. L. Bowley, M.A., before Section F of the British Association meeting at Cambridge.

gress. It is contended that the series used are consistent with and support each other, and that there has been steady progress decade by decade, though perhaps less rapid and continuous than the final series suggests. Other tests are considered, and rejected because of their incompleteness.

GENERAL NOTES.

HYDRAULIC MINING CARTRIDGE.—The General Report of Mines and Quarries for 1903 (Part 2, Labour) contains the following reference to the success of the Hydraulic Mining Cartridge, for which Mr. James Tonge, jun., was awarded the Shaw prize by the Council of the Society of Arts in 1902 — "Though coal-cutting machines will probably reduce the number of accidents from falls of roofs and sides owing to the fact that machine-cut faces are necessarily timbered systematically, they have introduced some fresh dangers. The most disquieting of these dangers is the increase of shot-firing which frequently follows the introduction of coal-cutters. The hope has long been cherished that some method of breaking down the coal and rock would be devised to supersede shot-firing. Lime-cartridges and patent wedges have been extensively tried from time to time, but have never been very successful. An hydraulic cartridge or wedge has now, in at least one colliery, proved a practical success and entirely superseded the explosives formerly used. Mr. Gerrard (District No. 6) gives interesting particulars of this contrivance. No less than 214,800 tons of coal were brought down with it and larger coal was obtained than by blasting. It was recently awarded the Gold Medal of the Society of Arts under the terms of the Benjamin Stone [Shaw] Bequest,— "For any discovery, invention, or newly devised method of obviating or materially diminishing any risk to life, limb, or health, incidental to any industrial occupation."

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock :—

NOVEMBER 30.—"The British Canal Problem." By ARTHUR LEE, J.P. The RIGHT HON. SIR MICHAEL HICKS BEACH, Bart., D.C.L., M.P., will preside.

DECEMBER 7.—"The International Exhibition at St. Louis." By WALTER FRANCIS REID, F.I.C., F.C.S. DR. BOVERTON REDWOOD, F.R.S.E., will preside.

DECEMBER 14.—"The Patent Laws." By CHAS. D. ABEL.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock :—

DECEMBER 8.—"Burma." By SIR FREDERIC FRYER, K.C.S.I. The RIGHT HON. the EARL of HARDWICKE, Under-Secretary of State for India, will preside.

January 19, February 16, March 16, April, 6 May 11.

COLONIAL SECTION.

Tuesday afternoons at 4.30 o'clock :—

January 24, February 28, March 28, May 23.

APPLIED ART SECTION.

Tuesdays, at 4.30 or 8 o'clock :—

DECEMBER 20 (8 p.m.).—"Street Architecture." By THOMAS GRAHAM JACKSON, R.A. DR. G. B. LONGSTAFF will preside.

January 31, February 21, March 21, April 11, May 16.

Papers for Meetings after Christmas :—

"The Navigation of the Nile." By SIR WILLIAM H. PREECE, K.C.B., F.R.S.

"The Protection of Buildings from Lightning." By KILLINGWORTH HEDGES, M.Inst.C.E.

"The Present Aspect of the Fiscal Question." By SIR CHARLES MALCOLM KENNEDY, K.C.M.G., C.B.

"British Woodlands." By The RIGHT HON. SIR HERBERT MAXWELL, Bart., M.P.

"The Supply of Electricity." By JAMES NELSON SHOOLBRED, B.A., M.Inst.C.E.

"Time Development in Photography, and Modern Mechanical Methods of carrying it out." By R. CHILD BAYLEY.

"London Electric Railways." By the HON. ROBERT P. PORTER.

"Lake Baikal and its Connection with the Great Siberian Railway." By ARTHUR GULSTAN.

"The True Musical Pitch of Notes we See and Sounds we Hear." By JOHN E. BORLAND.

"Popular Jewelry." By MONSIEUR LALIQUE (Paris). (*Applied Art Section.*)

"The Cape to Cairo Railway." By SIR CHARLES H. T. METCALFE, Bart., M.Inst.C.E. (*Colonial Section.*)

CANTOR LECTURES.

The following courses of Cantor Lectures will be delivered on Monday evenings, at 8 o'clock :—

DAVID JAMES BLAIKLEY, "Musical Wind Instruments." Four Lectures (with musical illustrations).

LECTURE I.—NOVEMBER 28.—Introduction—Music and the practical arts—Division of instruments into string, wind, and percussion—Limitation of definition—Wind instruments and the human voice—Acoustics and the art of instrument making—Vibration and wave motion—Every wind instrument a vibrating column of air—Stationary waves—Means of exciting vibration—Wave-form—Classification into brass, reed, and flute.

LECTURE II.—DECEMBER 5.—*Brass Instruments.*—Primitive instruments from horns and shells—Harmonic scale—Development into bugle and trumpet types—natural horns and trumpets—Introduction of slides, keys, and valves.

LECTURE III.—DECEMBER 12.—*Reed Instruments.*—Single and double reeds—Conical and cylindrical tubes—Bagpipes—Shawms, oboes, and bassoons—Clarionets—Saxophones.

LECTURE IV.—DECEMBER 19.—*Flutes.*—Modern limitation of the name—Action of the air-reed—Recorders and flageolets—Cone and cylinder flutes.

JAMES P. MAGINNIS, Assoc.M.Inst.C.E., M.Inst.Mech.E., "Reservoir, Fountain, and Stylographic Pens." Three Lectures.

January 23, 30, February 6.

DUGALD CLERK, "Internal Combustion Engines." Four Lectures.

February 13, 20, 27, March 6.

HENRY LAWS WEBB, "Telephony." Four Lectures.

March 13, 20, 27, April 3.

ALAN S. COLE, C.B., "Some Aspects of Ancient and Modern Embroidery." Two Lectures.

May 1, 8.

HENRY WILLOCK RAVENSHAW, Assoc. M.Inst.C.E., Mem.Fed.Inst.Min.Eng., "The Uses of Electricity in Mines." Two Lectures.

May 15, 22.

JUVENILE LECTURES.

Two lectures suitable for a juvenile audience will be delivered on Wednesday evenings, January 4 and 11, 1905, at Five o'clock, by Mr. CARMICHAEL THOMAS, Treasurer of the Society, on "The Production of an Illustrated Newspaper."

MEETINGS FOR THE ENSUING WEEK.

MONDAY, Nov. 28...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lectures.) Mr. David James Blaikley, "Musical Wind Instruments." (Lecture I.)

Surveyors, 12, Great George-street, S.W., 8 p.m. Mr. C. John Mann, "The Building Surveyor: his Training and Practice."

Actuaries, Staples-inn Hall, Holborn, 5 p.m.

Camera Club, Charing-cross-road, W.C, 8½ p.m.

Medical, 11, Chandos-street, W., 8½ p.m.

London Institution, Finsbury-circus, E.C., 5 p.m. Prof. Henry A. Miers, "The Diamond Mines of Kimberley."

TUESDAY, Nov. 29...Civil Engineers, 25, Great George-street, S.W., 8 p.m. Discussion on paper by Mr. John Francis Cleverton Snell, "Distribution of Electrical Energy."

Zoological, 3, Hanover-square, W., 8½ p.m. 1. Capt. Richard Crawshay, "Some Observations on the Field Natural History of the Lion," 2. Sir Charles Eliot, "Some Nudibranchs from East Africa and Zanzibar" (Part VI.). 3. Mr. R. Lydekker, "The Altai Lynx." 4. "Old Pictures of Giraffes and Zebras." 5. Dr. H. J. Hansen, "The Morphology and Classification of the *Asellota* group of Crustaceans, with descriptions of the genus *Stenetrium* and its species." 6. Mr. G. A. Boulenger, "The *Lacerta depressa* of Camerano."

Horticultural, Vincent-square, S.W., 3 p.m.

WEDNESDAY, Nov. 30..SOCIETY OF ARTS, John-street, Adelphi, W.C. Mr. Arthur Lee, "The British Canals Problem."

Royal, Burlington-house, Piccadilly, W., 4 p.m. Annual Meeting.

British Astronomical, Sion College, Victoria-embankment, E.C., 5 p.m.

THURSDAY, DEC. 1...Linnean, Burlington-house, W., 8 p.m. Prof. Sidney H. Vines, "Proteid digestion in Animals and Plants."

Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

Chemical, Burlington-house, W., 8 p.m. Mr. P. C Ray, "The Nitrites of the Alkali Metals and Metals of the Alkaline Earths."

London Institution, Finsbury-circus, E.C., 6 p.m. Col. Sir Thomas Holdich, "Tibet."

Tramways and Light Railways Association (in the ROOMS OF THE SOCIETY OF ARTS), John-street, Adelphi, W.C., 8 p.m. Mr. Stephen Sellon, "Running Powers."

Camera Club, Charing-cross-road, W.C., 8½ p.m.

FRIDAY, DEC. 2...Aeronautical (at the HOUSE of the SOCIETY OF ARTS), John-street, Adelphi, W.C., 8 p.m. 1. Major B. Baden-Powell (President), "The Aeronautical Exhibits at St. Louis Exhibition." 2. Mr. W. W. Dines. "Kites, Kite Flying, and Aëroplanes." 3. Dr. M. H. Hagesell, "The Work of the Aeronautical Commission." 4. Mr. Griffiths Brenow, "Captive Balloon Photography."

Civil Engineers, 25, Great George-street, S.W., 8 p.m. (Students' Meeting.) Mr. R. T. McCallum, "Midland Railway, West Riding Lines: the Construction of Contract No. 1."

Art Workers' Guild, Clifford's-inn Hall, Fleet-street, E.C., 8 p.m.

Geologists' Association, University College, W.C., Mr. A. E. Salter, D.Sc., F.G.S., "The Superficial Deposits of Central and parts of Southern England."

Philological, University College, W.C., 8 p.m.

Quekett Microscopical Club, 20, Hanover-square, W.C., 8 p.m.

Journal of the Society of Arts.

No. 2,715. VOL. LIII.

FRIDAY, DECEMBER 2, 1904.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

NOTICES.

NEXT WEEK.

MONDAY, DECEMBER 5, 8 p.m. (Cantor Lecture.) D. J. BLAIKLEY, "Musical Wind Instruments." (Lecture II. Brass instruments.)

WEDNESDAY, DECEMBER 7, 8 p.m. (Ordinary Meeting.) WALTER FRANCIS REID, "The International Exhibition at St. Louis, U.S.A."

THURSDAY, DECEMBER 8, 4.30 p.m. (Indian Section.) SIR FREDERIC FRYER, K.C.S.I., "Burma."

Further details of the Society's meetings will be found at the end of this number.

CANTOR LECTURES.

On Monday evening, 28th ult., Mr. D. J. BLAIKLEY delivered the first lecture of his course on "Musical Wind Instruments."

The lectures will be printed in the *Journal* during the Christmas recess.

CANTOR LECTURES ON MAJOLICA.

Prof. R. Langton Douglas's Cantor lectures on the "Majolica and Glazed Earthenware of Tuscany," have been reprinted from the *Journal*, and the pamphlet (price one shilling) can be obtained on application to the Secretary, Society of Arts, John-street, Adelphi, London, W.C. A full list of the Cantor lectures which have been published separately, and are still on sale, can be obtained on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

THIRD ORDINARY MEETING.

Wednesday, November 30, 1904; The RIGHT HON. SIR MICHAEL HICKS BEACH, BART., D.C.L., M.P., in the chair.

The following candidates were proposed for election as members of the Society:—

Chambers, John, Mokopeka, Hastings, Hawke Bay, New Zealand.
Hippisley, Clare Robert, 4, Belgrave-terrace, Bath.
Moorcroft, William, Marsh-avenue, Wolstanton, Staffs.
Owen-Jones, John, Shortmead-street, Biggleswade, Beds.
Peacock, James, 13, Fenchurch-avenue, E.C.
Sapara-Williams, Hon. C., M.L.C., Lagos, West Africa.
Smith, Thomas Strethill, 32, West-hill-road, Southfields, S.W.
Watkins, John, 48, Westbourne-street, Sloane-square, S.W.
Weston, Edward, 645, High-street, Newark, New Jersey, U.S.A.

The following candidates were balloted for and duly elected members of the Society:—

Aiyangar, S. Krishnasvami, M.A., Central College, Chamarajendrapet, Bangalore City, India.
Aldridge, Walter H., Canadian Pacific Railway Company, Canadian Smelting Works, Trail, British Columbia.
Alexander, W. W., The Town Clerk, Heidelberg, Transvaal, South Africa. (P.O. Box 201.)
Anderson, Robert Bruce, Assoc.M.Inst.C.E., 5, Westminster-chambers, S.W.
Attridge, Ernest William, Simons Town, Cape Colony, South Africa.
Austin, Henry B., J.P., Government Offices, Bloemfontein, Orange River Colony, South Africa.
Ayton, Ernest F., M.Am.I.M.E., Apartado Postal 141, Parral, Estado de Chihuahua, Mexico.
Ballantyne, William Smith, Mortgage-buildings, Pretoria, Transvaal, South Africa.
Balta, José, Ministerio de Fomento, Lima, Peru, South America.

Barnes, F. J., Portland Stone Quarries, Isle of Portland, Dorset.
Barton, Geoffrey Berkley, Guntakal, Southern Mahratta Railway, Madras, India.
Bellamy, Franklin J., Yeovil.
Bird, Frank Noel, A,M.I.Mech.E., Wellington Mills, Dardanup, Western Australia.
Black, Francis, R.B.A., Crofton, Mountfield-road, Church-end, Finchley, N.
Bodkin, Archibald Henry, 5, Paper-buildings, Temple, E.C.
Boot, W. H. J., R.B.A., Markeaton, Well-road, Hampstead, N.W.
Bourke, E. F., The Bourke Trust and Estate Company, P.O. Box 321, Pretoria, Transvaal, South Africa.
Brassey, The Hon. Thomas Allnutt, 4, Great George-street, S.W., and Park-gate, Battle, Sussex.
Buller-Allan, Edward, M.D., Maldon, Victoria, Australia.
Burns, Thomas, 25, Diana-street, Newcastle-on-Tyne.
Burton, Joseph James, Rosecroft, Nunthorpe R.S.O., Yorks.
Butler, Edwin T., 26, Craven-park, Willesden, N.W.
Carr-Calthrop, Colonel C. W., M.D., 51, Pembridge-villas, Notting-hill-gate, W.
Chand, Rai Bahadur Lal, M.A., Chief Court, Lahore, India.
Chilvers, George William, 59, Stile Hall-gardens, Chiswick, W.
Church, Harry, 138, Crystal Palace-road, East Dulwich, S.E.
Clark, Augustus, M.I.Mech.E., Recife, Pernambuco, Brazil, South America.
Clark, George Stirling, 35, Upper Belgrave-road, Clifton, Bristol.
Clayton, Charles E., A.I.E.E., City of London Asylum, near Dartford, Kent.
Cobbe, Hervic Nugent Grahame, F.G.S., care of Kalgurli Gold Mines, Ltd., Kalgoorlie, Western Australia.
Cock, Edward A. Langslow, Seremban, Federated Malay States.
Colston, Miss Lilian, 34, Curzon-street, Mayfair, W.
Cottingham, Captain Henry Langrishe, R.A., 70, Carlton-mansions, Maida Vale, W.
Dale, Thomas Henry, M.R.C.V.S., Government Experimental Farm, Potchefstroom, Transvaal, South Africa.
Däll, Alexander Percival, N.G.S.Ry., Secunderabad, Deccan, India.
Darby, Arthur Ernest, A.M.I.Mech.E., Town Hall, Wolverhampton.
Dickens-Lewis, George Edwards, Talbot-chambers, Shrewsbury.
Docker, Edward, Etaples, Pas de Calais, France.
Dollar, John A. W., M.R.C.V.S., F.R.S.E. (President of the Royal College of Veterinary Surgeons), 56, New Bond-street, W.
Dove, Frederick L., 15, Studd-street, Islington, N.
Ebstein, Mrs. Bertha, Leighton-house, Adrian-road, Stamford-hill, Durban, Natal, South Africa.
Edge, S. F., 3, Whitehall-court, S.W.
Edmonds, Captain Richard James, M.I.Mech.E., H.M. Gun Wharf, Portsmouth.
Ekberg, Miss Annie Elizabeth, Doveton-street, Ballarat, Victoria, Australia.
Enraght-Moony, Francis, Resident Commissioner, Mbabane, Swaziland, South Africa.
Fennell, John Howard, Rio Tinto, Spain.
Fleming, Robert, 2, Princes-street, E.C.
Forrest, George Topham, County Architects' Department, County Hall, Wakefield.
Fox, Alfred, jun., Assoc.M.Inst.C.E., care of Señor J. E. Harmsen, Arequipa, Peru, South America.
Frodsham, Harold, A.I.E.E., "E.C." Powder Works, Bean, *viâ* Dartford, Kent.
Fullwood, John, R.B.A., Studio, Slinfold, Horsham, Sussex.
Furnivall, F., East India United Service Club, 16, St. James's-square, S.W.
Galbraith, David Rankin Shirreff, F.I.C., Galbraith Iron and Steel Co., Ltd., P.O. Box 371, Auckland, New Zealand.
Gardner, Richard Core, 173, Fleet street, E.C.
German, Bernard Foster, care of Messrs. Grindlay and Co., Calcutta, India.
Gibbings, Major Henry Cornwall Cotton, Junior Naval and Military Club, 96, Piccadilly, W.
Gledhill, Gideon, Northfield, Edgerton, Huddersfield.
Gordon, Vivian, The Vache Park, Chalfont St. Giles, Bucks.
Granger, John Maxwell, care of Mrs. J. Mackenzie, Buller-street, Cambridge, East London, South Africa.
Grayson, George E., F.R.I.B.A., Greenbank, Egerton-park, Rock Ferry, Cheshire.
Greenwood, William, M.Inst.C.E., Cape Government Railways, Prieska, Cape Colony, South Africa.
Greg, Lionel Hyde, Dowlaishweram, Godavari District, Madras, India.
Grieve, James Henry, Assoc.M.Inst.C.E., El Damer, Sudan, Egypt.
Groves, Thomas, A.M.I.Mech E., Taiping, Perak, Federated Malay States.
Gurtoo, R., Chandni Chauk, Cuttack, Orissa, Bengal, India.
Hamilton, Charles Joseph, B.A., F.S.S., University College, Cardiff.
Harper, James, Assoc.M.Inst.C.E., Ferro-Carril Nord Este Argentino, Monte Caseros, Argentine Republic.
Hawthorn, John Henry, M.A., Municipal Technical School, The Newarke, Leicester.

Heron, J. S., Pennant-hills, New South Wales, Australia.

Higgs, Frederick, Station Works, Loughborough Junction, S.E.

Hollis, Sydney Ainslie, A.M.I.Mech.E., Town Hall, Bloemfontein, Orange River Colony, South Africa.

Hope-Edwards, Lieut.-Col. Herbert J., Netley Hall, Shrewsbury.

Houghton, Bernard, Moulmein, Burma.

Hutton, Richard B., Aldersbrook-house, Forest-drive, Manor-park, Essex.

Irani, Rustomji Hormusji, Thull-Parachinar Railway Survey, Thull, India.

Jackson, David Hamilton, Ph.D., M.A., 47, Mecklenburg-square, W.C.

Jeff, William, Northfleet District Engineering Works, Northfleet, Kent.

Jeffries, Joseph, A.M.I.E.E., 29, Court-road, Balsall-heath, Birmingham.

Jones, Bernard Gustave, A.I.E.E., 33, Commercial-street, Newport, Mon.

Jones, Cyrus, 282, Western Bank, Sheffield.

Khan, Khan Bahadur Sarfaraz Hosein, Patna City, Bengal, India.

Kisch, Stanley A., F.R.G.S., 31, Fox-road, West Bridgford, Notts.

Lagerwall, Richard Emil Magnus, Marylands, Gravesend, Kent, 157, Southwark-bridge-road, and 87, Sumner-street, S.E.

Landon, Will de Manoel, Wychwood, Poplar-grove, Sale.

Larkman, Alfred E., 78, High-street, Southampton.

Latimer, John, M.Inst.C.E.I., 12, Denny-street, Tralee, Ireland.

Leeson, Joseph George, 39, Tyrwhitt-road, St. John's, S.E.

Leigh, Arthur Graham, F.C.S., Chorcliffe-house, Chorley, Lancs.

le Sueur, Gordon, Kenilworth, Cape of Good Hope, and 29, Albemarle-street, W.

Linzell, Alexander Daniel, 49, Heathwood-gardens, Charlton, S.E.

Lockhart, Philip Henry, 22, Harley-house, Regent's-park, N.W.

Lord, F. A. B., A.I.E.E., Messrs. W. F. Dennis and Co., 49, Queen Victoria-street, E.C.

Lowcock, Charles Frederick, R.B.A., Roxborough, Clarendon-road, South Woodford, Essex.

McCallum, Edward Alfred, A.M.I.Mech.E., Russian Petroleum Co., Ltd., Baku, Russia.

McEwen, Samuel, A.R.S.M., 1, Lansdown-place, Brunswick-square, W.C.

Macey, Frank, High-street, South Ockendon, Essex.

McGregor, James, A.M.I.Mech.E., Fair-view, Melrose, N.B., and Natal Government Railway Locomotive Works, Durban, Natal, South Africa.

McIntyre, Miss J. A., West New Brighton, New York, U.S.A.

Maitra, Bhuban Mohun, K.I.H., Ghoramara P.O., Rajshahi, Bengal, India.

Manuel, Constantine, 116, Chancery-lane, W.C.

Mastin, John, R.B.A., 37 to 39, Foster's-buildings, High-street, Sheffield.

Maurice, R. T., 5, Macclesfield-street, Shaftesbury-avenue, W.

Mercer, Frank, 14, Prospect-road, St. Albans.

Mitra, S. M., M.R.A.S., Hyderabad, Deccan, India.

Moorhouse, Edwin, A.M.I.E.E., 2, Belmont-grove, Clarendon-road, Leeds.

Morgan, K. P. Vaughan, The Morgan Crucible Company, Ltd., Battersea Works, S.W.

Nathan, Henry, 11, Hanover-terrace, Regent's-park, N.W.

Nesbitt, Alexander Walter, M.I.Mech.E., 40, Dartmouth-row, Blackheath-hill, S.E.

Nichols, Henry John, A.M.I.Mech.E., 15, Fair-lawn-avenue, Chiswick, W.

Parasnis, D. B., Happy-vale, Sataro, Bombay, India.

Patel, Khan Bahadur Burjorjee Dorabjee, C.I.E., Quetta, Baluchistan, India.

Peattie, John, 18, Dorset-street, Baker-street, W.

Phillimore, Hugh Bouchier, Assoc.M.Inst.C.E., Kuala Lumpur, Federated Malay States.

Porteous, William, 14, Buckingham-street, Adelphi, W.C.

Pott, Francis Holliday, Messrs. Burt and Potts, 38, York-street, Westminster, S.W.

Pover, George Alfred Franklin, A.M.I.Mech.E., Cavendish-villa, 53, Hencroft-street, Slough, Bucks.

Reid, Edwin S., The National Conduit and Cable Co., Ltd., 1, Oxford-court, Cannon-street, E.C.

Reilly, John, F.S.S., 17, Nassau-street, Dublin.

Reyersbach, Louis, P.O. Box 149, Johannesburg, Transvaal, South Africa.

Robinson, John H., Lanthwaite, 42, Dartmouth-row, Blackheath, S.E.

Ronan, Barry, Somerville Hotel, Church-street, Maritzburg, Natal, South Africa.

Samson, John, 42, Parkhill-road, Hampstead, N.W.

Savage, G. H., Sunnyside, Cape Coast Castle, Gold Coast, West Africa.

Sawhney, Bhagat Ram, M.B., M.R.C.S., Chief Medical Officer, Jammu Province, Jammu, Kashmir State, India.

Semark, Charles Henry, Amroth, London-road, Faversham.

Sharpe, Charles James, 130, Fenchurch-street, E.C.

Shepheard, Herbert B., A.I.E.E., Falkirk, Grange-road, Ealing, W.

Sherry, Richard H., Westlake, Grahamstown, Cape Colony, South Africa.

Shirley, Arthur, 122, Castlenau, Barnes, S.W.

Shorter, John, 193, Clarence-street (P.O. Box 469), Sydney, New South Wales, Australia.

Singh, Professor Kishan, B.A., 21, Golden Temple, Amritsar, India.

Slinn, Edward John, J.P., 19, Park-road, Watford, Herts.

Smith, Harry, Natal Harbour Department, Durban (P.O. Box 28, Point), Natal, South Africa.

Smith, Miss Gertrude, 3, Wilton-road, Merton-park, Wimbledon, S.W.
Smock, John C., Trenton, New Jersey, U.S.A.
Sopwith, John, A.M.I.Mech.E., Bridge-house, Blackwall, E.
Spangler, Prof. Henry Wilson, Department of Mechanical Engineering, University of Pennsylvania, Philadelphia, U.S.A.
Spencer, Charles F., York-chambers, Halifax.
Spenlove-Spenlove, Frank, R.B.A., The Corner House, 69, Addison-road, W.
Sperring, A. E. O., "The Cigar and Tobacco World," 150, Holborn, E.C.
Spielmann, Isidore, 56, Westbourne-terrace, Hyde-park, W.
Sproule, George Huston Russell, A.M.I.Mech.E., Locomotive Depôt, C.S.A. Railways, Braamfontein, Johannesburg, South Africa.
Steers, William E., care of National Bank of South Africa, London-wall, E.C.
Stovin, Cornelius Frederick, M A., Medical Officer of Health, Council Offices, Ilford, Essex.
Swinney, Herbert, 27, Bridge-street, Chepstow.
Taylor, Frederic Henry, 14, Victoria-street, S.W.
Thomas, R. H., The Transvaal Tin Mines, Oshoek, *viâ* Carolina, Transvaal, South Africa.
Thompson, James, 14, Preston-road, Westcliff-on-Sea.
Thomson, Edward John, Western Club, Glasgow.
Tolhurst, John. Glenbrook, Beckenham, Kent.
Tyler, Harold William, Entebbe, Uganda, *viâ* Mombasa, British East Africa.
Van Raalte, Emanuel, 2, Glasshouse-street, Regent-street, W.
Varley, Jesse, Longleat, Paget-road, Wolverhampton.
Verde, Comandante Felice, Via Fazio 7, Spezia, Italy.
Victory, Louis H., "The Leinster Leader," Ltd., Naas, Ireland.
Wainwright, Joseph, 15, Bolton-road, Port Sunlight.
Wallis, H., District Engineer, Cape Government Railways, De Aar, Cape Colony, South Africa.
Warner, Thomas W., Messrs. Kinton, Warner and Co., 25A, Ægis-buildings (P.O. Box 1,147), Johannesburg, Transvaal. South Africa.
Watkin, Henry, Watcombe-house, Waterloo-road, Burslem.
Watson, Hugh Munro, Kildonan, 22, Coleraine-road, Blackheath, S.E.
Wetzler, Joseph, M.I.E.E., 203-208, Temple-chambers, Temple avenue, E.C.
Whitwell - Allen, George, 35A, Geraldine - road, Wandsworth-common, S.W.
Williamson, H., A.M.I.Mech.E., Messrs. Samuel Samuel and Co. (P.O. Box 273), Yokohama, Japan.
Winter, Frank, A.C.A., 12, Sanderson-road, Newcastle-on-Tyne.
Woods, Harry, A.M.I.Mech.E., Kalline Tea Estate, Kalain, P.O., Cachar, India.

The paper read was—

THE BRITISH CANALS PROBLEM.

By Arthur Lee, J.P.

When a great system of railways was first established in this country it seems to have been hastily assumed that canals would be no longer necessary, and that their decay and ruin might be regarded with equanimity. The railway companies were allowed to obtain control of 1,138 miles of canal, out of a total of 3,906, and these, to use the words of a witness before the Select Committee of 1883, were "so adroitly selected as to strangle the whole of the inland water traffic."

During the past twenty years, largely owing to the action taken by the Society of Arts, the Mansion House Association, and the Associated Chambers of Commerce, public interest in our inland waterways has been revived, but although a vast amount of information upon the subject has been obtained, very little has been done to turn it to practical account. With the single great exception of the Manchester Ship Canal, no improvement of any consequence has been made in the system of inland waterways which was in existence in this country before 1825. Not only is this the case, but long lines of water communications once open have been allowed to fall into ruin and decay, and in this respect we are worse off than we were during the early part of the last century.

It may be that those are right who assume that we may view the decay and ultimate destruction of our inland waterways with equanimity, that in the railways we have all that is necessary as a means of transport, and that the sooner we close up our canals, and turn the land they occupy to other purposes the better for the community. But before we adopt such a policy, it is well to remember that Great Britain alone of all the great trading nations in the civilised world pursues a policy of deliberate neglect of her inland waterways.

At the instance of the Bristol Chamber of Commerce, the Associated Chambers recently obtained from the Foreign Office a series of reports upon

The Policy Adopted by our Continental Competitors

with regard to inland water communication. The British Consuls in France, Holland, Belgium, Germany, and Austria, were instructed to report specially upon the following points:—

(1) As to the capital expended during the

past twenty-five years in developing the waterways, and the methods by which they have been improved.

(2) As to the tolls chargeable upon traffic, and the manner in which interest on capital expended is provided for.

(3) As to the results which have followed improved means of transport by water (*a*) with regard to the railways, (*b*) with regard to the seaports, (*c*) with regard to the trade and commerce of the country.

These reports deserve the earnest study and consideration of the trading community.

France.—Torn and impoverished by the war with Germany, the French nation set itsel resolutely to work immediately peace was declared to improve its industrial condition. One of the first great measures undertaken with this end in view was the appointment of a Commission to enquire into railways and other means of communication. The Commission found that the canal system of France had been neglected, and they recommended that immediate steps should be taken to improve it. "If there be devoted to it," they said, "but a small fraction of the efforts which for twenty years have been concentrated exclusively on railways, great results will follow." "The disjointed manner and want of foresight with which a great part of the barge service is carried on must be altered. It must cease to consider itself a moribund industry, and must apply itself to commercial exigencies."

The enterprise of the French people promptly followed this recommendation by vigorous action. Between 1872 and 1878 France spent £9 640,000 on the improvement of her waterways and maritime ports. In 1879 a new and comprehensive scheme was drawn up. In the execution of this programme £18,000,000 was spent between 1879 and 1900. The total length of first-class waterways was increased from 906 miles to 2,930 miles of newly constructed canals.

The French waterways at present in the hands of public bodies other than the State form only an insignificant fraction of the whole; practically the whole of the waterway system is the property of the State which maintains it out of the funds free of all tolls.

The justification of a system of toll-free canals is to be found in the Report of the Government Commission of 1872:—

"If," says that Report, "the canal promotes agricultural improvements, stimulates the establishment of factories, facilitates the working of mines, quarries, and forests: increases in a word the public wealth, the State, its inevitable partner, takes its share of all such increased wealth, and that share is perhaps sufficiently large to do away with the necessity of levying any direct toll. It is thus that the State and Departments have been enabled to construct and maintain roads without demanding any toll from the public who use them. It is this fact alone which, though in a less degree, admits of the existence of these canals from which the State realises a moiety of the expenses of maintenance. But under such apparently erroneous liberal views lies a true perception of the wants of the country, which induces the State before everything to augment its wealth and production, and also a profound equity of taxation for the impost laid upon wealth created by help of the canals diminishes the burdens of the whole community, even of that portion of it which does not make use of them."

The result of an expenditure in France of over £27,000,000 on navigable waterways has been attended by a great development of the water traffic, and it is noteworthy that during the same period the railway traffic has also largely increased, though far less rapidly in proportion. M. Picard, then President of Public Works, at a meeting of the State Council, spoke of the canal built to connect the Marne with the Rhine, as having given a wonderful impetus to the mineral and other industries of Lorraine—industries which could not have been born, according to him, except for cheap transit facilities. "Minerals," he said, "which lay undisturbed before its construction are now being actively extracted; factories and furnaces are so numerous upon its banks and press so closely upon each other that one might imagine them sprung up from the earth." In fact "83 per cent. of the industries upon its banks have been established since the canal was cut."

By a law passed Jan. 30th, 1902, a new credit, amounting to over £28,000,000, was voted to extend the system of French waterways.

This amount is allocated as follows:—

Improvement of existing waterways	£2,425,200
New waterways	19,195,000
Improvement of waterways	6,523,000
	£28,133,200

This expenditure is to be recouped by tolls to be levied as follows:—

On boats, 1-15th of a penny per ton per mile.
On goods, Class 1, 3-5ths ditto.
On goods, Classes, 2-4, 3-20ths ditto.

Germany.—Mr. Gastrell, the Commercial Attaché to the British Embassy in Berlin,

reports that during the earlier period of the development of the railways up to 1875 there existed in Germany, as in most other countries, a feeling that inland transport by water was doomed to languish, it being thought impossible that it should ever be able to compete with the extensive railway systems. Even the best-informed persons in the early days of the German Empire after 1871 only believed in a survival of canal transport as competing in certain districts with the high roads. Since 1875, however, public opinion gradually looked more favourably on the possibilities of a development of the inland waterways.

The expenditure on the waterways in Germany in the ten years 1890-1899 was £14,950,320, and it has been found, with the continued improvement and extension of the waterways and harbour accommodation, that inland shipping has considerably increased. The general practice as regards the levying of dues is to leave the navigation on the open river free, while imposing charges in many cases for the use of harbours and wharfs; on all canals regular charges are made for the navigation. Public opinion in Germany differs as to the extent to which dues can be properly collected. One view is that interest on the capital invested on waterways should be provided entirely out of the navigation dues, while another view is that all expenditure (except for the cost of furnishing special facilities) should be paid by the State in order to provide absolutely free waterways on the same footing as high roads. In 1900 the actual length of the waterways within the German Empire was, according to Imperial statistics, 8,798 miles.

A further expenditure of £22,000,000 is contemplated to be made to extend the German canal system. This will provide a network of satisfactory waterways through the whole of North Germany, an improved waterway between Berlin and Stettin, the construction of the Dortmund Rhine canal, and of a canal from Bevergen on the Dortmund Ems canal to Hanover.

Austria-Hungary possesses internal navigable waterways of the approximate length of 4,000 miles, on which between 1848 and 1898 £21,000,000 were expended. Mr. Bennett, the Commercial Attaché to the British Embassy at Vienna, reports that owing to the rapid development of the railway system at the beginning of the latter half of the nineteenth century, river traffic in Austria-Hungary as elsewhere lost for some time the importance which it had previously possessed, and it almost seemed that on some rivers it would come to a complete standstill. To this circumstance may be ascribed the fact that it is only of comparatively recent date that earnest attention on the part of the State has been given to river regulation, for it has become evident in the face of the ever increasing traffic, that the railways are not in a position to grant those cheap rates which economic interests demand, more especially for the carriage of bulky merchandise of small value.

By the law of June 11, 1901, over £10,000,000 were voted for the construction of a network of navigable canals in Austria and for the necessary river regulation in connection therewith. The first period of construction is reckoned from 1904 to 1912, at the expiration of which a new credit will be demanded for the completion of the scheme.

The internal navigable waterways of Hungary possess a total approximate length of 3,082 miles. In 13 years the river traffic of the country has increased from 2,520,000 tons to 3,640,000 tons. With the projected new navigable canals on a large and comprehensive scale the question of inland navigation is entering upon a new and important phase, and is at the present time largely absorbing public attention in the Dual Monarchy.

Belgium.—In Belgium the capital expended by the State during the period extending from 1875 to 1900 on the improvement of navigable waterways and harbours is estimated at £16,000,000. The State administers the greater portion of the system, but certain portions of the inland waterways are administered by the provinces, some by communes and municipalities, and a small proportion has been conceded to companies, associations of landowners, and individuals.

As a general rule the tidal rivers are exempt from tolls. Upon the canals tolls are levied at so much per ton of freight for each kilometre. These tolls are based on an exceedingly low scale, the rate fixed being under 1-6th of a penny per ton per kilometre on rivers which have been rendered navigable by means of locks, and 1-20th of a penny on canals. The traffic on the navigable waterways has grown enormously, from 250,000,000 mile tons in 1880 to 560,000,000 mile tons in 1900, an increase of 124 per cent., while at the same time the tonnage of freight transported by railways has trebled.

Finally it is reported that although it is impossible to estimate even approximately the

extent to which the improvement of the waterways has contributed to the great development of traffic, yet it may be justly claimed that in providing the country with a system of navigable waterways and cheap transport, in multiplying the points of contact between road, rail, and water transport, and thus facilitating transhipments, in rendering the seaports easier of access and in stimulating the erection of numerous commercial and manufacturing establisments, this work of improvement has been one of the principal factors of the commercial prosperity of the country.

Holland.—Long before the construction of railways the waterways of Holland were the traffic carriers of both goods and passengers throughout the land at rates so low that competition on the part of any other known means of transport was, and remains, a practical impossibility so far as local goods traffic is concerned. As late as forty years ago there were only three existing lines of railway of any importance in Holland, and these had a hard struggle for existence. About the year 1860 the urgent necessity for railways was forced upon the Government, but it was impossible to induce private capital to undertake a competition with the abundant and excellent waterways with which the nation was provided. The construction of a considerable network of railways was therefore undertaken by the State and with excellent judgment, for the railways have proved the salvation of many districts which seemed doomed to decay. The State railways were constructed at the cost of the nation, and after considerable discussion as to the means of working them to the best advantage they were handed over to a private company expressly promoted for the purpose, the State providing the permanent way and the buildings, while the company provided the rolling stock and *personnel* and worked the new lines to the best advantage. The surplus of receipts over expenditure exclusive of that on capital account is divided in certain proportions between the State and the company. The latter has paid fair, but not large, dividends to the shareholders, while the amount received by the State has never sufficed to pay more than one per cent. per annum on the capital which it has expended.

Notwithstanding the fact that it was necessary to establish a system of State aided railways to supplement the existing excellent inland waterways, Holland has spent large capital sums in the improvement and extension of the waterways themselves. Between 1862 and 1901 nearly £17,000,000 sterling was thus expended, the most important work being the Merwede Canal connecting the port of Amsterdam with the Rhine. Mr. W. C. Robinson, the British Consul at Amsterdam, reports that the building of this canal has had a very favourable influence upon the prosperity of the port. The total tonnage of Rhine and other traffic using the canal has increased from 1,420,257 tons in 1892 to 4,433,257 tons in 1899. This great increase of tonnage was not carried out at the expense of the competing railways, as on the contrary, the quantities of goods reaching and leaving Antwerp by railway show also a marked increase.

The net result of a careful study of the continental traffic systems proves that

The Experience of Continental Nations has been that both canals and railways are necessities, and that increase of traffic on the one means increase of traffic on the other. France and Germany, after the advent of railways, seem to have neglected their canals for a time, but speedily awoke to the conclusion that this was a mistaken policy, and, during recent years, have expended many millions of capital to bring their ancient waterways abreast of modern conditions. Holland, which was so admirably served in the matter of waterways that private capital could not be found to build railways to compete with them, discovered that to rely upon canals alone would mean the impoverishment of whole districts, and that railways must be built, and equipped, even to the extent of providing them in great measure at the cost of the State.

In Great Britain

we are still discussing the question of what shall be done with our canals, and have not yet arrived at any practical conclusion. I readily admit that the conditions under which trade is carried on in this country may make a continental analogy misleading, but is it the case that the conditions are so different that we can afford to altogether disregard the experience of our neighbours and competitors? It is argued that despatch is of paramount importance in this country, and that a large amount of traffic is forwarded in small consignments. It is true that in the matter of despatch and the transit of small consignments the railway is much superior to

the canal; but this only proves the experience of Holland that the railway is an absolute necessity, even with the most perfect system of inland waterways which has yet been devised. Does the converse hold true, and is the continental experience that the maintenance of the inland waterways is a necessity even when an excellent railway system exists, applicable to this country also? I am strongly of opinion that it is, and that we cannot afford to ignore the supreme efforts which are being made by our competitors to cheapen transport.

The fact is, that in this country, as on the Continent, there are two descriptions of traffic. The one generally moved in bulk, of low value per ton, and in which speed in the matter of transit is of minor consequence, the other generally moved in comparatively small consignments, of high value per ton, or in which speed in the matter of transit is of great importance. Speaking generally, the difference in the two classess of traffic is the difference between raw materials and manufactured goods. For the carriage of the one the railway is pre-eminently fitted, for the carriage of the other the waterway is the more economical. It is significant that in England the manufactories in the neighbourhood of our great ports can be distinctly traced along the lines of the canals.

It is very plausibly argued that matters may be left to take care of themselves. Goods which can be more economically carried by canal will go by that route, and those which can be most favourably carried by rail will preferably go by that means of transit, and the fact that canal traffic languishes in this country is proof that it is not suited to our methods of trade.

Arguments of this kind leave altogether out of account

The Policy of the British Railway Companies with regard to Canals.

I believe this to have been based on an entire misconception of what was best for the interests of the community, and even of the railway companies themselves. From the start, the companies have regarded the canals rather as rivals to be crushed, than as useful auxiliaries to whom could be handed the traffic it would not pay to send by rail. Every trader is aware of the vast difference made in the rates charged by railway companies to and from towns with effective waterways, and to districts where these waterways do not exist, or have been rendered inoperative by neglect. Given equal rates, traffic will go by rail, as the saving of time, and convenience of dealing with small consignments, will always operate in favour of the railways. But as a consequence of the present policy of the railway companies the respective tonnage of goods conveyed to competing points by rail, or canal, is no criterion of the economic advantage of the two systems for a particular kind of traffic.

A case in point is the result of the improvement of the Severn navigation. In 1890, the Severn Commissioners went to Parliament, and obtained an Act, empowering them to raise £30,000, and to expend it in deepening the channel between Worcester Bridge and Gloucester, to a minimum depth of 10 feet at low summer level, and in other works of improvement.

These improvements were carried out between 1891 and 1894, and have not resulted in any great improvement of traffic, for the reason that the railway companies lowered their rates from the sea ports to Worcester and the towns on the Severn route, to a point at which they could retain the traffic which would otherwise have found its way by canal.

But the managers of railway companies must earn sufficient to pay a dividend to their shareholders, and the loss made by carrying traffic to competitive points at unremunerative rates is made up by charging higher rates than would otherwise be necessary to points where the railway has a monopoly, so that the community generally, suffers by the action of the railway companies in their endeavour to crush water-borne traffic.

In a paper handed by Mr. Conder to the Select Committee on Canals, which sat in 1883, an exhaustive analysis is made of the practical result to the railway companies of the low rates charged by them for certain descriptions of traffic. Mr. Conder estimated that in 1877, the loss to the shareholders of railway companies on the carriage of coal to London alone amounted to £822,000 per annum, and if this be correct the total loss to-day must be largely in excess of these figures. The heavy mineral traffic carried by the companies has necessitated an enormous capital expenditure in the duplicating and quadrupling of their main lines, and in the building of miles of sidings and station accommodation. It would appear, if the calculations of Mr. Conder are only approximately correct, that both railway shareholders, and the whole community, would be largely in pocket if the companies con-

fined themselves to the traffic which needs quick delivery and can bear comparatively high rates, leaving the traffic which can be more economically water-borne to that method of transport.

The determination of the railway managers to secure every description of traffic, even at a loss, has had the further effect of

Stopping the Improvement of the Water-ways.

Capital is not likely to be attracted when it is known that expenditure is likely to be made unremunerative by such a competition as that to which I have alluded. Although there are some exceptions, yet, speaking generally, the condition of our waterways is worse than it was seventy years ago; meantime the modern requirements of commerce have become more and more exacting, and no industry can possibly flourish which does not progress with the times, and in which improved facilities are not constantly provided.

An improvement urgently needed is a nearer approach to a uniformity of gauge on existing canals. Take, for instance, the communication between Birmingham and the Bristol Channel ports. One portion of this communication is *viâ* the tidal waters of the Severn, where it is not safe for small canal barges to navigate. As far as Worcester, 43 miles from Gloucester, river barges can be navigated with maximum dimensions of 135 feet in length by 22 feet in width, and a draft of 8 feet 6 inches, but for the 30 miles to Birmingham, the largest barge which can be accommodated is only 71 feet 6 inches in length, 7 feet in width, and drawing only 4 feet of water.

The consequence is that every bit of water-borne traffic between Birmingham and the Bristol Channel ports must be transhipped either at Worcester, or at Gloucester, and this necessity for transhipment causes not only great delay but a cost which is altogether disproportionate to the total cost of the journey.

Another difficulty is that of gettting

Through Rates on Canals,

any portion of which is owned or controlled by the railway companies. The Birmingham Canal Navigation consists of a network of canals 158 miles in length, which is controlled by the London and North-Western Railway Company. According to an authoritative statement made by the Birmingham Canal Company, the London and North-Western Railway Company, in 1846, agreed to pay in perpetuity £4 per share per annum on 17,600 shares then existing. These shares had cost altogether £645,000, so that the guaranteed payment amounts to 10½ per cent. on the capital invested. The local traffic on the canal amounted in 1898, according to the Board of Trade return, the last made, to 7,131,022 tons, but the through traffic was only 1,578,730 tons. The through traffic is in fact diverted to the railway company, and serves as a feeder to it instead of to the canals in connection. Every trader interested knows how this is effected.

What is to be Done.

The problem is a difficult one, but as business men we ought to face it, and settle it. I believe that the great majority of the trading community are of opinion that continental nations are right in the conclusion to which they have arrived that rail and water communication are both necessities. I believe that further the great majority are of opinion that the conditions under which trade is carried on in this country are not so different from those of the Continent as to enable us to treat our inland waterways with indifference, without our being handicapped in competition with our rivals abroad. We cannot forget that transit charges are an element in the cost of production, and the manufacturers in a country in which transit is cheap, and is conducted on the most economical lines, must be more favourably situated, other things being equal, than in a country in which transit charges are dear. Nor can we forget that if the railway companies charge rates, which involve a loss at competitive points, they must recoup themselves where they enjoy a monopoly.

If the railway carriage for a certain class of goods is more costly than water carriage, the community bear the whole of the loss even though the rates are the same at competitive points.

It has been suggested that

State Control

of canals will solve the difficulty, and a resolution was proposed by the Manchester Chamber of Commerce at the last meeting of the Associated Chambers to the effect that the time has arrived when the British Government should take under its control the whole of the canals of the country, and work them in the public interest, or as an alternative, place them in the hands of a national trust with a Government guarantee, supervision, and control.

Although it is true that these are the lines along which continental nations have moved, I believe that the conditions in this country are such that this proposal is outside practical politics, at the present time. Parliament is already overburdened with work, and to what Government department is it proposed to confide the necessary supervision and control? Is it the Board of Trade? Does the attitude of Parliament towards commercial matters entirely commend itself to business men? And is the Board of Trade as at present constituted an ideal institution to which to confide a matter of this kind? It must not be forgotten that even if a National Trust is called into being for the special purpose of dealing with canals, yet if it is to have the disposal of public funds, it must be under the control of some Government department, and of Parliament itself. But beyond considerations of this kind, there is one great difference between continental nations and ourselves which must be taken into account. Upon the Continent, for the most part, the harbours are made and maintained by the State: with us they have been made, and maintained, either by private enterprise or by municipal authorities. Is it proposed to transfer the British docks and harbours to the State? If so, has the magnitude of such a change and all that it means been considered by those who advocate State control of our canals?

If not, how are the conflicting and competing interests of our ports to be brought into harmony? The canals and the railways are the great feeders to the ports. Will Liverpool view with complaisance the expenditure of national funds to improve the port of Bristol? Will Southampton relish a large expenditure to which it must contribute its share for the improvement of canals which will tend to divert trade to London?

There is yet another question which demands consideration. The Manchester proposal is to the effect that the British Government should take under its control the whole of the canals in the country. It is useless to shut our eyes to the fact that there are some canals in existence upon which the possible traffic will never be sufficient to justify expenditure being made upon them. It is useless to attempt to work a system of waterway navigation between points where traffic is not likely to be moved in bulk, say in quantities of a minimum, as a general rule, of 20 to 25 tons. In districts where there is a considerable mineral traffic, or between the ports and the great centres of industry in the Midlands, canal traffic may be developed to economic advantage, but a sparsely populated district, or one along the line of which neither mines, quarries, nor manufactories exist is best served by the railway. The experience of Holland is to the point. It was there found absolutely necessary if districts of this kind were not to fall into decay, that rail communication should be provided even when an almost perfect system of waterways was in existence. Upon lines of communication, which are not fitted for the transit of goods in bulk, canals are not needed, and the land they occupy may be turned to more profitable account. What is necessary is to decide upon the points which may be economically served by waterways and to put these into a condition in which they may be turned to useful account.

I am of opinion that the problem can be best solved by powers being given to

LOCAL AUTHORITIES

to form canal trusts and to acquire and improve certain lines of waterways to serve local districts. Such a method of procedure would be in harmony with the whole system of legislation to which we have been accustomed. The canals are analogous to the highways. In continental countries the highways are generally maintained by the State, but in this country the roadways are maintained and controlled by the local authorities. Some of the great ports are entirely maintained by the municipalities; in others municipal authorities are largely represented on the Boards which control them. There is one important difference between the Continent and Great Britain, inasmuch as that in the one case the ports are comparatively few as compared with the inland population to be served, and are nearly all in the hands of one authority; in the other they are many, they are in hands of different authorities, and keenly compete against each other for business. I believe that the many conflicting interests of the British ports would be best served by allowing them to work out their own salvation in combination with the inland districts served by them.

Such a scheme was embodied in the Canal Traffic Bill, prepared by the Bristol Chamber of Commerce, adopted by the Canals Committee of the Associated Chambers, and brought into the House of Commons by Sir Henry Holland in 1901. The objects of this

Bill were to extend the powers conferred by the Board of Trade with regard to derelict canals under the Railway and Canal Traffic Act of 1888 to any existing canal, and to authorise the formation of public canal trusts. It would have empowered local authorities to combine to take over the management of existing canals, and to subscribe to the expenses of the formation or promotion of public canal trusts. It would have enabled canal companies to dispose of their undertakings to public canal trusts, and a canal trust was defined as any body of persons who are otherwise than for private profit entrusted with the duty or invested with the power of improving, managing, regulating, and maintaining a canal or navigable river.

The Bill followed the precedents set in the derelict Canal Clauses of the Act of 1888, in the Light Railways Acts, and in the Acts under which local authorities control, and maintain the highways, and its provisions were generally approved by the Board of Trade. Owing to the congested state of Parliamentary business, and the fact that it was opposed by the railway interest, the Bill did not get a second reading, and the same fate awaited it on its re-introduction in the sessions of 1902-3. The present state of Parliamentary business, is such that a measure introduced by a private member, if opposed, has a very remote chance of obtaining a second reading, still less of passing into law, and the commercial community have some ground for complaint that the Government did not give facilities for its passage.

On December 13th, 1900, a deputation from the Associated Chambers had an interview with the President of the Board of Trade upon the subject. Mr. Gerald Balfour, in the course of of that interview, said, "He had not heard it suggested that the Government should undertake the work of developing and managing inland navigation. He must dismiss that proposal—nothing was more alien to our general way of managing things in this country."

So far some of us may agree with the President of the Board of Trade, but he went on to ask for the submission of definite proposals upon lines similar to the Light Railways Act of 1896. "If," he said, "the Associated Chambers of Commerce would appoint a Committee of their own to draw up a scheme and embody it in a Bill the Board of Trade would give it careful consideration." With business-like promptitude the Chambers of Commerce accepted the challenge, and at their next meeting a strong committee was appointed consisting of representatives of London, Manchester, Birmingham, Wolverhampton, Cardiff, Oldham, Worcester, Bristol, Liverpool, Hull, Stroud, Belfast, Dublin and Greenock. This committee met and agreed to adopt the Bill to which I have alluded, as drafted by the Bristol Chamber. On May 12th, 1902, the Chambers again sought an interview with Mr. Gerald Balfour, who admitted the importance of the agitation, and promised to consult his colleagues in the Government, with a view to their acceptance of a second reading, on condition that the Bill be then referred to a Select Committee. We have been able to secure nothing further and are still waiting the redemption of Mr. Balfour's promise, and the answer of his colleagues. I confess that some of those who have taken an active part in this matter, would hail with pleasure the advent of a strong business man at the head of a department which is charged with the facilitating the business of a nation.

I would like to emphasise

The Importance of this Matter to the Midlands.

Warwickshire, Staffordshire, Shropshire, and Worcester, form a great manufacturing centre; their food and raw materials imimported from abroad must come to them through the ports, and cheap transport from the ports to the Midlands is of vital consequence to the great Midland industries. The amount of food stuffs imported into the district of which Birmingham is the centre, is about 700,000 tons annually, and a similar quantity of timber is also annually brought there. Added to this the Birmingham district imports something like 1,700,000 tons a year of copper, tin, lead, iron ore, and zinc. Roughly speaking, in food and raw materials, the district imports about 3,000,000 tons annually. Every shilling a ton saved means £150,000 saved to the ratepayers of the district, and this on the import trade alone.

At least I plead for

A Business-like Common-sense Manner of Dealing with the Question.

It is not business nor common-sense to pursue a policy of drift. It is neither business nor common-sense to complain of the severity of foreign competition, and at the same time to

neglect any means by which our manufacturers may be placed in a better position to compete with their foreign rivals.

It is neither business nor common-sense for a responsible statesman seriously to ask a body of business men, representative of our great trading interests, to spend time and thought in formulating a definite proposal upon a question of great importance, and when the proposal is made, to treat it with complete indifference.

I will go further, and say that in view of the strenuous efforts made by foreign Governments, it is neither business nor common-sense for the commercial affairs of the nation to be treated in the haphazard fashion to which we are unfortunately accustomed in this country.

The Secretary read the following letter from Mr. Philip Stanhope, M.P.:—

Dear Sir,—I regret extremely that I shall be absent in the provinces on November 30th, and therefore cannot be present on the occasion of the reading of the Paper by Mr. Arthur Lee upon the "British Canals Problem," as it is a subject in which I have long taken an active interest, having introduced into Parliament, during several successive years, a Bill to deal with the question, and having attended Canal Conferences on the Continent.

I confess I have been hitherto much disheartened by public apathy in the matter, which is nevertheless, of transcendent importance to our trade; but I am glad to see that Sir Michael Hicks Beach is about to give the movement his powerful aid and encouragement. Please express my regret to your Council.—Yours faithfully, Philip Stanhope.

DISCUSSION.

The Chairman, in opening the discussion, said that he did not profess to pose as an authority upon the question, and yet he could not say that he had not had some personal experience on it, and on matters more or less closely connected with it. He had had the honour for a good many years of representing the City of Bristol in Parliament, and that city had been pre-eminent in attempting to do for itself, at the cost of the ratepayers, an analogous work to that suggested by the author, namely, that of providing large dock accommodation for its trade, at the expense of many millions. He was a resident in the county of Gloucester, and the County Council of Gloucestershire had taken the initiative as a local authority in endeavouring to re-open for navigation the old Thames and Severn canal, which had practically become derelict for many years. That had been done at an expense which he was afraid had led to grumbling on the part of many ratepayers, although he did not think it had been at all extravagant, but it was yet too soon to prophecy as to what the results of the work would be. He had also been President of the Board of Trade, and as an ex-president of the Board of Trade he ventured to deprecate the strictures on the present holder of that office which had been passed by Mr. Lee. He knew better than the author the difficulties of anyone holding that office in obtaining time from the House of Commons for the consideration of the matters which he might desire to bring before it; and it did not at all follow that because Mr. Gerald Balfour had not been able to take any active steps in the matter now under consideration, that he was not in sympathy with the proposals suggested in the paper, or would not do his best to endeavour to carry them into effect. He (the Chairman) did take some steps in the matter as President of the Board of Trade. Sixteen years ago he was responsible for carrying the Railway and Canal Traffic Act through Parliament, an Act containing many clauses dealing with canals. It empowered the Railway Commissioners to fix through-rates for different canals in the public interests; it empowered them to prohibit unreasonable rates on canals fixed by railway companies interested in those canals, and endeavouring to divert traffic from the canals on to their railways; it forbad any railway company or a director or officer of any railway company from obtaining an interest in a canal, unless through special authority given by a special Act of Parliament; and it enabled canal companies to institute a clearing house for canal traffic precisely in the same manner as the Railway Clearing House which existed to-day; in fact it brought the tolls of canals under the jurisdiction of the Railway Commissioners precisely as the rates on railways were brought under their jurisdiction. Finally, where a canal was derelict, or practically in a condition which made it impossible to carry traffic over it, it enabled the Board of Trade to relieve shareholders of all liability of that canal, and to transfer it to a local authority, or to another body of persons who would undertake to put it and maintain it in good order. So that he thought it would be seen that as long ago as 1888 he not only had the question under his cognisance but also took steps which in those days were considered of importance towards improving the inland navigation of this country. He was afraid the result had not been what they hoped and perhaps anticipated; he was afraid the inland navigation of this country was not now in a condition such as they might desire. The author in the first part of the paper compared the action of other countries with our own. He thought in all such matters it must be remembered that, whether rightly or wrongly, it was the practice in this country to leave everything as much as possible to private enterprise, and it was the practice in continental countries to undertake everything as far as possible by the State. Two different systems had to be dealt with, and he did not

think it at all followed that, taken as a whole, the English system was wrong. What were the results? During the last forty years France was stated, by the author, to have expended, or to be intending to expend, about 55 millions upon inland navigation and harbours; Germany, 47 millions; Holland, 17 millions; and Belgium, 16 millions; and he was afraid, with the exception of a very considerable improvement in the navigation of the Thames, no important work had been done in this country in regard to inland navigation, except the Manchester Ship Canal. What were the reasons for that state of affairs? In the first place, the circumstances were not quite the same, as the author admitted. England was not favoured with those great natural waterways which continental countries possessed. In proportion to its area he thought this country was a more hilly country, and therefore less favourable to the construction of canals than the plains of France or Germany, or the flat levels of Holland. But there was something more than that. England was infinitely better supplied with railway accommodation than any continental country, and he should say a greater proportion of the traffic of the country was traffic which would not go by canal, and was essentially railway traffic than in the countries which had been named. Our passenger traffic, the small consignments of goods which formed so large a part of English trade, and perishable and valuable goods would not go by canal, and he thought it would be found that articles of that description formed a larger proportion of the total traffic than they did in the countries with which comparison had been made. Therefore the circumstances were not quite the same. Further, it must be remembered that some of the expenditure in the countries which had been quoted, was not expenditure on inland navigation but on harbours, and he was quite sure that nobody would contend that England had been remiss in that kind of expenditure in recent years, or that we had not expended on our harbours, in different parts of the country, quite our fair share of the world's expenditure under that heading. But, making allowance for everything of the kind, there was unquestionably a most important difference between the way inland navigation had been treated in England in the last 40 years, and that in which it had been treated in continental countries; and he was prepared to associate himself with the author's words, when he said that we could not afford altogether to disregard the experience of our continental rivals on the subject. The influence of cheapened transport by sea had been immense on the fortunes of the world in the last 50 years, perhaps greater on the fortunes of this country than on the fortunes of any other country, and if it were possible for England, at any reasonable cost, to obtain cheapened transport by land for its industrial products, he was bound to say he thought it would have a very important influence upon the future of the country. The author had very ably grappled with the question of what could be done. Mr. Lee demurred, not perhaps on the ground of principle, but on the ground of its practicability, to the proposal which had been made in many influential quarters that the State should assume the control and ownership of all the canals at the cost of the ratepayers, that it should institute a great system of inland navigation, and should place the canals at the disposal of persons desiring to use them absolutely free from tolls, just as the roads were. He knew something of the House of Commons, and he was absolutely certain that they would no more obtain the assent of the House of Commons to a proposition of that kind than they would to the most impossible proposition that anybody present could conceive. It was not merely that it would be very strongly opposed by an extremely powerful interest, the railway interest, who would say, with some reason, as the author had suggested, that when Parliament had allowed and encouraged them to spend many millions in perfecting their system of railways, it would be a little hard that the public funds should be utilised in order to establish a system of canals to compete with them—but it must be remembered that there were persons in this country (and he thought an increasing number of persons, although perhaps the advocates of the change were not among them), who did feel the burden both of taxation and rates, and the influence of those persons on the House of Commons would be such that he was quite certain it would never entertain a proposal of the kind. If that were impracticable, what was the alternative? The author had put forward an alternative based on the section of the Railway and Canal Traffic Act of 1888, extending that section which now affected only derelict or practically useless canals, to all canals, and enabling them to be taken up by local authorities, either singly or combined, for that purpose. That was a practical proposition which he thought certainly deserved the consideration of Parliament. He did not himself believe that it would lead to the re-opening of all their canals—he did not think it ought to. Take, for example, the Basingstoke Canal, for which nobody would give anything the other day; it would be unreasonable to expend the money of the ratepayers in attempting to re-open that canal for public purposes. He knew a canal in the north of the county of Wilts, which, at the present time, was practically useless, and on which he thought no reasonable person would propose that public money should be expended in order to restore it for purposes of navigation, and there were many similar instances in the country where he was quite sure local authorities would never dream of availing themselves of such powers if they were entrusted to them. But there were cases where it would be possible for local authorities to benefit their districts very greatly indeed by some expenditure of the kind. The author had referred to the great producing district of the Midlands of which Birmingham was the centre, and which naturally desired means of communication with the sea; he had said that there was a line of waterway from Birmingham

to the Bristol Channel ports, but that practically it was rendered useless because the canal between Worcester and Birmingham was so small that it would only admit barges of very small dimensions. If the whole of the waterway were made capable of accommodating vessels of the size which now could go right up to Worcester from the sea, surely that would be a means of competition with the railway system from Birmingham to the coast, which might be of enormous advantage to the trade of Birmingham and the midland districts. Other examples in the country might be found where a judicious expenditure on the part of the local authorities, either singly or in combination, might enable the waterways to be completely utilised, instead of being comparatively useless, as they were at the present moment. He ventured to suggest that if it were possible to approach the matter on such lines, more practical good would be done than by a far larger scheme, such as he had already referred to. If they could get one step towards the attainment of their object, something would be secured; while if they insisted on a great scheme, which he did not for a moment believe could be carried, they were simply postponing any advance in the desired direction. No one could overrate the importance of the matter to the country, and the author had dealt with it with an ability and moderation, which must excite all their sympathies.

Sir JOHN BRUNNER, M.P., after thanking the Chairman for supporting the author's project, which he considered was of very great value, said he hoped that even although at the beginning, the brave experiment made by the Gloucestershire County Council might not succeed, if they obtained a good through rate from Gloucestershire to London their expenditure might prove hereafter to have been an extremely wise one. The Chairman had stated that the Act of 1888 had been up to the present time almost inoperative, but it was hardly to be expected that as long as canals continued in their present condition, differing in gauge as they did so many times on a long journey, any advance would be made. Nevertheless the Act of 1888 was still considered of importance, and only last session a concession was obtained from the railway companies under the Act. The Chairman had spoken of the practice in this country of leaving all public work to private enterprise, and had given him the impression that he was entirely hopeless of making any changes. The doctrine of *laissez faire* under which they had acted hitherto became fashionable at the solicitation of the free-traders of the forty's and fifty's, who, telling the nation that they wanted to be left alone, imposed the idea upon the imagination of the people to such an extent that they had been unable to shake it off; but he hoped the example set not only by all the nations of Europe, but by every colony of Britain in the world, would induce them to change their system. There was no doubt that the canals, no matter what they did with them, would play a humble *role* as compared with the railways, but nevertheless he had hoped that the business men of the country, and the Government following the business men, would help the canals to perform that *role* to the best advantage of the nation. The author had given irrefutable reasons for taking a step in advance. He had mentioned what had been done by Austria-Hungary, and it was interesting to remember that the Minister who had done most to promote inland navigation recommended his policy as being the one which would divide the people of the country the least, and because it would calm down racial differences. He hoped the policy the author had suggested, which was a policy of all for all, might tend to diminish political differences amongst them. Mr. Lee had stated that a good many of the Canal Commissioners at the time of the great extension of railways in the forties actually insisted upon the railway companies buying them up, in spite of the fact that they were doing very good business. He was in a position to state that he believed the Manchester and Liverpool Chamber of Commerce at the next meeting of the Associated Chambers next March, would not demand, as they did at the Manchester meeting, that the Government should buy up all the canals, but would recommend that it should have the power to buy such canals as it thought should be bought in the interests of the country. He hoped the House of Commons would shortly mend in its treatment of such matters, and that it would not push aside with cold indifference any demand on the part of the mercantile community for State aid. If the mercantile community would only make up its mind what it wanted, and ask for it, he believed they would get it. He was an advocate of unity of ownership, but the author was afraid that local jealousies would prevent progress. In his opinion it would be a mistake to allow local jealousies to influence their actions, and they would be wise if they made the control and ownership central in order that the real consideration daily before the minds of those who managed the concern should not be local interests but the general interests of the community. The Chairman thought it was Utopian, but he (Sir John) did not think it was true economy to refuse to spend money when it was known that the money would bring in a good result; and therefore he should not think it wise on the part of any section of the community to refuse, on the plea of economy, to proceed in that direction. He was satisfied that the people of the country would gain very greatly indeed as a community and as an Empire if they made up their minds to proceed on the lines France had taken.

Mr. L. F. VERNON HARCOURT said he had visited the canals in the different countries which had been mentioned. On the French waterways it would be found that the traffic was large in some parts of the

country and small in others, the heavier traffic occurring where there was a great amount of bulky goods. The same remarks also applied to Belgium and Germany. It must be remembered, in discussing the question, that the rivers in continental countries were much larger than those in England, and that, therefore, the connections between the rivers were of much greater importance, while the lines of communication were considerably larger than in this country. Nevertheless, he did not think the canals of the country should be neglected as they had been in the past. One or two waterways had maintained their position and held their place with success against railways, notably the Aire and Calder Canal and the Weaver Navigation. But canals for large traffic did not depend so much upon the goodness of their waterway as upon the presence of bulky goods. The waterway from Birmingham to the Severn, *viâ* Worcester, although it was a short one, was a bad one. He thought it would be possible to make a beginning there, and he could not understand why the people of Birmingham had not carried it out. He agreed with the author and the Chairman that it would be impossible to buy up the whole of the canals of the country; the suggestion that that should be done had tended to delay the improvement of certain waterways, owing to the impossibility of improving all the waterways whether they gave a return for their traffic or not. It would be a great advantage if, as Mr. Lee suggested, the different ports had powers granted to them to improve the waterways communicating with them. The Board of Trade had been found fault with. He thought it would be advisable that the control of the canals should not be under the assistant-secretary for railways, but under an assistant-secretary for commerce or harbours, because more interest would be shown in the undertaking if it was in the hands of those who had similar matters to deal with.

Mr. E. PARKES, M.P. (Birmingham), said it appeared to him that if the question under discussion could be satisfactorily settled it would go a considerable way towards settling the question of foreign competition, especially in the Midlands. Everyone agreed that the author had made out his case; the question in dispute was the remedy. There were two propositions before the country, nationalisation and municipalisation. At the time Mr. Lee brought the matter before the Chamber of Commerce, municipalisation was the plan which was more or less favoured; but he (Mr. Parkes) reminded the meeting that if the Bill suggested had been passed it would only have been a permissive Bill. The result would have been that the same divergence of opinion, the same jealousies, the same impossibility of the committees to find money or pledge their rates for the purpose of developing this or that canal would have existed as before the passing of the Act, and it was that which was the great bar to the accomplishment of the object in view. The Town Council of Birmingham appointed a committee which went into the matter most thoroughly, particularly with regard to improving the waterway between Birmingham and the Bristol Channel ports. Why was nothing done? Birmingham people raised the objection that while the traffic between Birmingham and London and Liverpool represented 90 per cent. of the trade of the town, the trade with Bristol represented only 3 to 5 per cent. Birmingham wanted a scheme which would improve the connection with Liverpool and London. Sir Alfred Hickman brought forward a proposal for enlarging the existing canals at a cost of between three-quarters of a million and one million pounds, which sum was to be raised by pledging the rates, not only of Birmingham, but of the surrounding districts, representing a population of two or three millions, to the extent of 2d. or 3d. in the pound, but the whole of the municipalities refused to accept the proposal. The business communities of the country would be devoutly thankful to any Government of whatever party which would take the matter in hand. He believed that if the Bill suggested by the author was passed they could hope for very little indeed from the municipalities. In the case of the canal between Birmingham and London or Liverpool, all the municipalities, boroughs, and counties along that route would have to be taken into consideration. It was said at the Manchester meeting that the general opinion had veered round from the municipal to the national point of view. It appeared to him that the national point of view would be the most feasible and the most workable, because all the different conflicting interests which he had referred to could thus be harmonised; but the Chairman had said there was not the remotest possibility of Parliament taking it up, and as the municipalities would not take it up, they had arrived at an *impasse*. A strenuous effort should be made to overcome this *impasse* by harmonising the different views at present existing, so that a united appeal by all concerned could be made to the Government to take the matter in hand.

Mr. G. WESTALL regretted that the author had not given more statistics with regard to the traffic of some of the principal canals in order that a comparison might be made with the traffic on some of the practically derelict canals. He had also expected that Mr. Lee would refer to the rivers which were the feeders of the canals. Some years ago he interested himself in endeavouring to reopen a carrying business between London and Oxford, but he found that the navigation of the Thames was extremely bad, the depth of water in some cases not exceeding three feet; but the greatest difficulty arose because of the extremely bad arrangements that existed in the port of London for the collection of goods. Probably a whole week would be spent in collecting goods deposited in different docks in order to get a full freight for one barge; and the extremely shallow state

of the river made navigation impossible in some cases. He remembered the time when the canals of the country decayed not altogether because of the competition of railways, but because of their own defects; they were so small that they could only carry such freights as made it impossible to realise any profit. In the case of the Birmingham and London Canal, there was a good waterway for 80 miles through the Grand Junction Canal, with 14 feet locks, but for the remainder of the distance the locks were only 7 feet wide, necessitating the employment of boats which must not carry top loads. He thought it would be perfectly useless and throwing away money to acquire many of the existing canals; no proposition was worth considering which did not provide a canal capable of taking a barge conveying 250 tons weight.

Mr. B. I. BELISHA said he came from Manchester, the Mecca of inland navigation in this country. It was very unfortunate that whilst so many able and thoughtful men were agreed that something was necessary to be done, there should be a division of opinion as to ways and means, but he did not think the differences were so irreconciliable that after mature consideration a *modus vivendi* could not be adopted. A policy was required that would unite the people of the country the most, and the paper would go a long way in educating public opinion on the question. There were such difficulties both with regard to the nationalisation and municipalisation of the canals, that for a time an effort must be made to combine and adopt a middle course, as suggested by the author. There was, no doubt, an advantage in public authorities dealing with the question, as was evidenced by the City of Manchester lending at the critical moment five million pounds for the completion of the Manchester Ship Canal, which had been and would be an immense advantage to the whole of the community of the country. If the policy suggested by the author was to be adopted, a beginning must be made somewhere, and there was no better place in which it could be begun than in Manchester.

Mr. MARTIN WOOD thought the question was one of urgent national importance from the point of view of competition with continental countries. As the author had said, no improvement had taken place in water communications in this country for 70 years, and it was high time something was done to put the manufacturers of the country in a position to compete on more level terms with their continental rivals.

Mr. P. E. GAUNTLETT (Basingstoke Canal) said that after having giving the subject of canals the deepest consideration for many years, he agreed with the Chairman's method of dealing with the problem. If anything was to be done it must be done in a permissive way, giving the County Councils power to purchase canals as they thought proper. The Chairman had also pointed out why Holland had succeeded and England had failed. Holland was flat and there was an abundance of water, while the tolls on the canals were so low that they defied effective railway competition. One of the principal difficulties in England was the difference in the gauge of the canals. If money could be obtained to improve the various undertakings he believed a new system could be set up which would be of great advantage to the trading community. No one had touched on the most important subject of all in dealing with canals, namely the question of water. Water evaporated so quickly in the summer on some of the canals that it was impossible to run a barge. The Chairman had referred to the unfortunate Basingstoke Canal. It was quite true it had been unfortunate, but the cause of that was that it had been mismanaged. There were great possibilities in front of the Basingstoke Canal, only it required a man of courage with a little money to make it a success.

Mr. LEE, in reply, said that he was a plain, practical business man, and he only wanted that which was practical. If the gentlemen who advocated State control of canals would only put their views on paper, and try to elaborate a Bill under which their ideas would be carried into effect, he would be exceedingly glad to see it; but he believed when they did sit down and put their pens to paper they would find out what the difficulties in the way were. He presumed that, as Mr. Parkes had suggested, it would be a compulsory measure, and he was rather curious to know how they would suggest obtaining by compulsion from the railway companies the canals which they had been compelled to take up under pressure from the canal companies themselves. He was very pleased that Mr. Parkes had come down from Birmingham, because he hoped that gentleman would go back as a missionary to his district, which needed a missionary very badly. More cold water had been thrown upon the project in Birmingham than in any other town. He would like Mr. Parkes to tell his friends in Birmingham that although it was perfectly true the great majority of the exports of Birmingham went *viâ* Liverpool and London, yet 35 per cent. of the imports came from the Bristol Channel ports, and the committee, to which Mr. Parkes had alluded, seemed to have forgotten altogether the importance of the import trade, which to Birmingham was of greater importance, as far as canal communication was concerned, than the export trade itself.

The CHAIRMAN, in proposing a vote of thanks to Mr. Lee for his able paper, said he had gathered in the course of the discussion that the representative of the Basingstoke Canal was obliged to admit that private enterprise would not provide the necessary capital to place the undertaking in proper order, that one of the representstives of

Birmingham in Parliament said there was no hope from municipal enterprise, and the conclusion, therefore, appeared to be that they must come upon the taxpayers of the country generally. He had some Treasury instincts still left in him, and he rather deprecated that conclusion. Sir John Brunner had his best wishes as to the future, but he was sure that gentleman would not forget that when the Government which he desired took office one of its first pledges was reduction in the expenditure of the country.

The resolution was then put and carried unanimously.

BRITISH WHEAT SUPPLY.

If in the early days of the last century it had been predicted that at its close the population of the United Kingdom, which in 1800 was not much over 16,000,000, would exceed 41,000,000, whilst the area under wheat cultivation would be less than 2,000,000 acres, the one forecast would have found few to accept it, and the other would have been received with derision. It was taken as axiomatic that just as the high prices ruling at the time resulted in the agriculture of the country advancing with rapid strides, so great increase in population, and a greater individual rate of consumption consequent upon increased wealth and altered habits, would keep prices at a profitable level, and foster the growth of wheat. Up to 1874-5 this is pretty much what happened. The abnormal prices of the great war passed with it—in 1813, the price of wheat was £5 9s. 9d. per quarter, in 1816 it had fallen to £3 18s. 6d.; but land—the raw material from which food is produced—being limited in amount, and in increasing demand, necessarily rose in price. So much was this the case, that whereas the average price of wheat for the five years preceding 1875, was £2 15s. per quarter, as compared with £5 2s. 6d. for the five years preceding 1815, the rent of land was much higher in 1875 than it was in 1815. It is during the last thirty years that we have seen the anomaly of population and wealth increasing rapidly whilst the area under wheat steadily decreased. The following figures make this clear:—

AREAS OF CEREAL CROPS IN THE UNITED KINGDOM.

1875.

	Acres.
Wheat	3,514,088
Barley	2,751,362
Oats	4,176,177
Total	10,441,627

1900.

	acres.
Wheat	1,901,014
Barley	2,172,140
Oats	4,145,633
Total	8,218,787

These figures show that the area under wheat shrank in the twenty-five years by nearly one half. Nor was the land taken from wheat cropped with one or both the other cereals. The acreage under barley shows a shrinkage of about 22 per cent., and the acreage under oats is less. And yet in the interval the population had increased by nearly 10,000,000! Since 1900 the acreage under wheat has continued to diminish. The preliminary statement of agricultural returns for Great Britain for 1904 gives the wheat acreage at 1.375,284 acres, as compared with 1,581,587 for 1903. The total quantity of wheat estimated to have been grown in Great Britain in 1904, amounting to 36,880.246 bushels, is the smallest crop on official record. The shrinkage in the last three years is shown in the following figures:—

	Bushels.
1902	56,676,783
1903	47,642,816
1904	36,880,246

It was assumed by Caird and others that the advantage of position would always give the British farmer a great advantage over the foreigner, but experience has proved it to be somewhat illusory. The Kansas or Minnesota farmers' wheat does not have to pay for carriage to Liverpool more than 2s. 6d. to 7s. 6d. per ton in excess of the rate paid by a Yorkshire farmer, and the difference does not go far towards enabling the latter to pay rent, tithes, rates, and taxes. In 1872 the imports of wheat and flour into the United Kingdom were only 9,469,000 quarters, in 1900 they had increased to 23,196.000 quarters, and bearing in mind the figures as to acreage in cultivation given above, it is clear that with the continued growth of population the imports of foreign wheat must continue to increase.

The world is our granary, but there is much shifting in the sources of supply. Thus in 1872 Russia sent us more wheat than any other country. In that year our chief supply was obtained as follows:—

	Qrs.
Russia	4,168,000
United States	2,030,000
Germany	910.900
France	660,000
Egypt	536,000

Here we have Russia supplying more than twice as much as the United States, and neither India nor Argentina represented. In 1900 the position was very different.

	Qrs.
United States	13,561,000
Argentina and Uruguay	4,322,300
Canada	1,877,100
Russia	1,031,700
Australasia	883,900

The imports from Germany and France had become insignificant, and Egypt had dropped out. Russia had fallen to fourth place, the United States supplying more than half of the total import of 23,190,800 quarters.

Coming to the present year, we find another great shifting. The following figures are taken from page 28 of the Trade and Navigation Returns, giving the imports of wheat into the United Kingdom for the ten mouths, January-October, 1904 :—

	Cwts.
British East Indies	20,469,100
Argentina	18,466,700
Russia	16,827,100
Australasia	9,268,400
United States	6,541,100

It would not be safe to base definite conclusions on the figures of the ten months of the present year given above, but it may be taken as certain that in future we must look to other countries than the United States for our chief wheat supplies.

In his presidential address before the British Association for the Advancement of Science (1900) Sir William Crookes gave it as his opinion, that "It is almost certain that within a generation the ever-increasing population of the United States will consume all the wheat grown within its borders and will be driven to import like ourselves." It is difficult to believe that men of forty may live to see the United States importing wheat, but they may well live to see an end of American (U.S.) exports of wheat. Americans whose opinions are entitled to great respect take this view of the matter. For example, Mr. James J. Hill, speaking at Minneapolis in January of this year said:

"There was a time when our popular campaign song was, 'Uncle Sam is rich enough to give us all a farm.' To-day he has not any farms to give us that we can cultivate. All of the agricultural land that can be cultivated without irrigation is gone, and the people are selling their houses in the United States and moving out into North-Western Canada, west of Winnipeg, where they can buy land from 6 dols. to 10 dols. per acre. More people have gone there than many of our men would like to acknowledge."

That may be an exaggerated statement of the case but it is significant to find a leading agricultural journal in New York State asking "Whether we have not reached the end of our era of wheat exportation; whether perhaps we are not approaching the time when we shall become importers instead of being exporters of this staple." And the writer goes on to point out that "There are forces at work that must ultimately cut off our exports of wheat, and will certainly, in time, render us unable to raise our own supply. One of them is the tendency of the American farmer to shift from wheat to Indian corn. This is really an advance from primitive to complex agriculture, for corn means cattle and other live stock; the marketing of meat instead of grain; the return of fertility to the land. Thus wheat exhausts the soil, corn (fed to live stock) restores it; new land only can grow wheat at a profit." Moreover, America has to meet the serious competition of other wheat-producing countries, and to sell her wheat at prices determined by international considerations, and not simply by the quality of her own harvests.

Losing our wheat supplies from the United States, can we reckon upon full supply of our wants from other countries? There seems little reason to doubt it, but it is not likely that the British East Indies will continue to head the list as it does for the past ten months. In 1900, India was unable to export a single grain of corn, but in normal years the imports from that quarter should be large. In a lesser degree, we must reckon with fluctuations in the Russian supply. The following figures indicate the extent of these fluctuations in the last four years :—

	Cwts.
1901 (12 months)	3,487,400
1902 (10 months)	4,118,684
1903 (10 months)	13,036,203
1904 (10 months)	16,827,100

Notwithstanding the war, Russia has sent us in ten months of 1904 nearly five times as much wheat as we received from her in the whole of 1901; but it may be taken that, owing to the war, the imports of Russian wheat in 1905-6 will show a great falling off. So with Australasia. Drought plays havoc. In 1903 we received 26 cwts. from Australia and 4 cwts. from New Zealand, in all from Australasia 30 cwts. In 1901 we got none from Western Australia, and none from Queensland and Tasmania. In the ten months of the present year to October 31 we have received 8,959,800 cwts. from Australia and 308,600 cwts. from New Zealand. The imports from Argentina may be expected to increase, but the farming industry in the Argentine Republic is not on a satisfactory basis. The farmer often has no interest in the land beyond the growing crops, a percentage of the harvest being the rent charged by the owner of the property. Little attention, too, is paid to methods of cultivation, as the farmer has no resources to help him if the cereal crops fail. Still, when the supply fails in one quarter, it is pretty safe to count upon its being made good in others, for the sources of supply are constantly broadening.

Probabilities point to the Dominion becoming in the course of the next few years our greatest and steadiest supplier of wheat. Few on this side have any accurate idea of the enormous wheat-producing capacities of that great country. In the quality of its produce, in the yield per acre, in the quantity of farming land available, in the prices of farming land, in the matter of Government assistance, in facilities for

marketing, in the general conditions under which farming is carried on, Canada, by the authors of that valuable little book, "Canada and the Empire," has already a striking advantage over the United States. Messrs. Montagu and Herbert quote official figures to show that the Dominion may be in a position within comparatively few years, after supplying all home demands, to furnish Great Britain with all the wheat and flour she requires and leave a surplus for export to other countries. The conclusion is arrived at in this way. Putting the imports of wheat and flour into Great Britain as equivalent to about 200,000,000 bushels of wheat, were one-fourth of the land said to be suitable for cultivation in Manitoba and the three Provisional Territories under crop with wheat annually, and the average production equal to that of Manitoba for the past ten years, the total crop would be over 812,000,000 bushels. This would be ample to supply the home demand for 30,000,000 of inhabitants (supposing the population of Canada should by that time reach that figure), and the present requirements of Great Britain three times over. And it is well to bear in mind that Canadian flour is the finest in the world, better even than the best brands of Hungarian, if we have regard to the quantity of albuminoids in it. Of course, the extension of the wheat area depends upon labour, and until recently the population of the Dominion grew but slowly. Of late, however, immigration has increased enormously, eightfold in eight years. The "American invasion," as it is called, commenced in 1896, and in 1903 sent to Canada 47,000 settlers. In 1903, the immigrants numbered 124,000, as against 67,000 in 1902, and 49,000 in 1901. It must be some years before the Dominion takes the place, so long held by the United States, as our chief granary, but there can be no reasonable doubt that our wheat supplies from the Dominion will rapidly increase, and that by the time the supplies from the United States altogether fail, the Dominion will have gone a considerable way towards making up the deficiency, whilst Argentina, India, and (if peace comes soon) Russia will pour in supplies that will prevent any very serious rise in the price of wheat, though we are not likely to see it again any where near the ruinous figure at which it was quoted in 1894, namely £1 2s. 10d.

NEW SOUTH WALES TIMBERS.

Mr. J. H. Maiden, F.L.S., has published at Sydney (under the authority of the Minister for Lands), "Notes on the Commercial Timbers of New South Wales," from which the following remarks are taken:—

Forest Wealth of the State.—I have no desire to use the language of exaggeration, but I can safely say that New South Wales is one of the most richly-endowed countries in the world as regards its forest wealth. I should be sorry to say that our timber supplies are unlimited—far from it; but, with our small population, we have large areas of practically virgin forest, and, in many places, as the trees are cut out, numbers of young trees are coming forward and flourish without hindrance, thus ensuring the stability of the supply of many of our timbers.

With few exceptions, most of our trees require no artificial replanting; what is simply required is conservation—protection of the young growth from damage by animals, fires, &c., and, in certain cases, what is called "thinning," which consists in destroying or weeding out sickly, malformed, or overcrowded saplings. Conservation should be our watchword.

Most of our valuable timbers are found in the coast and coast-mountain districts. A few, *e.g.*, the cypress pines of the western districts, and the ironbarks of Dubbo (and thence to the north-east) are found in the drier parts of the State.

The commercial timbers of this State are now being depicted by the author of this pamphlet in a handsome quarto work, "The Forest Flora of New South Wales."

The eucalypti are also specially and more fully dealt with in a work written by him, and entitled "A Critical Revision of the Genus Eucalyptus."

Supply of Good Timbers not Unlimited.—The demand for our timbers has been so active during the last few years, and fashion has set in almost exclusively for a very few species, that a word of caution is necessary. We have large quantities of excellent timber—there is no doubt of that; but not so much that we can afford to cut recklessly, and neglect conservation of young growths. We must not forget that the giant trees, the monarchs of our forests, which have yielded large quantities of high-class timber, are being rapidly cut out. They have been maturing their timber through the ages, practically uninterfered with by the aboriginal lord of the soil, and are no more to be replaced than can the nuggets which man can do nothing to produce; he simply reaps a harvest which he has not sown. The cutting out of forest without replanting or conservation of young forest growths is simply living upon capital, and, continuing the metaphor, we should seriously ask ourselves if we are establishing an adequate sinking fund.

Timbers for Export.—As regard the export trade, as the merits of our hardwoods become more fully realised, a largely increased demand may reasonably be expected to set in for them. Our soft pine may, perhaps, be utilised for butter-boxes. Our figured brush timbers have to win their way to recognition in the world's markets. This will necessarily be slow, but we have much valuable evidence as to their merits to encourage us to make them more widely known.

Timbers are only exported, as a very general rule, from the coastal strip. We have, however, a number of useful timbers whose use is local for reasons of transport.

Too great care cannot be exercised in seeing that timber which is sent to market, and particularly that intended for export, is not only good of its kind, but

also belongs to a species of acknowledged merit. In the cases of trees or timbers which bear a resemblance more or less strong to valuable timbers, the greatest care should be exercised.

Merits of many of the Timbers as yet unknown.—A number of our timbers are being tested as regards their suitability for wood-carving, and there is reason to suppose that we possess a fair number of timbers useful for this purpose. My own feeling is one of regret that the art of wood-carving has been so neglected in this State, as it is a specially useful art, and, as time rolls on, a considerable amount of employment will be available, both to men and women carvers of decorative work, for fittings of buildings, furniture, &c., to say nothing of more purely art objects for the decoration of the home, &c. And not only will wood-carving prove a remunerative occupation for many people, and a useful accomplishment for persons of leisure, but it will be the means of drawing public attention to the texture and properties of our native timbers, and of utilising some of those which at the present time are put to no particular purpose.

In the second part of his report, Mr. Maiden gives a classification and description of the commercial timbers of the colony, and in the third part, a list of the timbers which can be used for special purposes, ending with the following notes on wood paving and wood pulp :—

Wood Paving.—May I, at this place, insist that timbers of a kind should be kept together in wood-paving? No two timbers are of such similar texture in all respects that they wear absolutely equally when formed into a roadway. A road engineer would never dream of laying together stone cubes of various materials. The irregularity in wear of a wooden roadway is especially detrimental, and I desire to raise my voice against the pernicious doctrine that our timbers may be mixed in the same stretch of roadway. There is no excuse for mixing them, as they can be readily separated by any man who has devoted some attention to the subject, and timbers not of the first class would stand a better chance of useful employment if they formed strips of roadway by themselves.

Wood Pulp.—It is desirable to ascertain whether any of our timbers can be utilised commercially for pulp in paper-making. This investigation must be preceded by determination of the cellulose in our timber.

OPTICAL CONVENTION, 1905.

The Optical Convention will be held in London at a date towards the end of May, 1905.

The President is Dr. R. T. Glazebrook, Director of the National Physical Laboratory. The list of Vice-Presidents includes Sir William Abney, Lord Blythswood, Sir W. H. M. Christie, Astronomer Royal, Earl of Crawford, Lord Kelvin, Lord Rayleigh, and the Earl of Rosse. The Treasurer is Mr. E. B. Knobel, and the Honorary Secretary Mr. F. J. Selby.

The main object of the Convention is to bring into close sympathy and co-operation men interested in optical matters, from all sides of the question, theoretical, practical and commercial. This it is proposed to do by holding a series of meetings for papers and discussions on optical questions; and a "Papers" Sub-Committee has been appointed with Prof. S. P. Thompson as chairman, and Mr. S. D. Chalmers as secretary.

It has also been decided to organise an exhibition, of a scientific character, of instruments manufactured in this country, with a view to showing the great progress recently made and of stimulating further efforts.

Instrument makers and manufacturers are invited to assist the committee by sending for the purpose of the exhibition typical instruments and apparatus of their manufacture. It is not proposed to ask exhibitors to pay for space, but a nominal sum, to defray out of pocket expenses, would be charged to each firm whose goods are shown. This charge would not exceed one guinea for each class in which goods are exhibited.

An illustrated catalogue will be prepared, which will describe the special character and advantage of any particular instrument. It is hoped that the catalogue may be especially serviceable to manufacturers in making their instruments known in colonial markets. An Exhibition and Catalogue Sub-Committee with Dr. Mullineux Walmsley as chairman, and Mr. F. J. Selby, as secretary, is already at work. A provisional list of classes which they have drawn up for the exhibition and catalogue is appended. Firms desiring to have their manufactures included in the catalogue, or to send apparatus for exhibition, are requested to communicate without delay with the secretary, and to forward as early as possible descriptions and particulars of their instruments.

The following is the suggested classification of instruments:—(1) Materials and tools; (2) simple optical elements and testing apparatus; (3) astronomical instruments; (4) nautical instruments; (5) surveying instruments; (6) meteorological instruments; (7) spectacles and eye-glasses; (8) telescopes and binoculars; (9) microscopes and accessories; and apparatus for photo-micrography; (10) photographic apparatus; (11) projection apparatus; (12) apparatus for optical measurement—spectroscopes—refractometers—polarisation and interference apparatus—apparatus for measurement with optical aids; (13) photometric apparatus; (14) heliographs—range-finders; (15) stereoscopes; (16) ophthalmic instruments and appliances; (17) apparatus for educational purposes; (18) mathematical and drawing instruments—calculating apparatus; (19) shop fittings and miscellaneous; (20) historical collection; (21) literature.

OBITUARY.

GEORGE VIVIAN POORE, M.D., F.R.C.P., M.P.C.S.—Dr. Poore, Emeritus Professor of Medicine and Clinical Medicine at University College, London, and consulting physician to the hospital, died at his house at Andover on Wednesday, 23rd November, after a long illness. He was a member of the Society of Arts, and in January, 1885, he delivered a course of three Cantor Lectures on "Climate, and its Relation to Health." Dr. Poore, the son of Commander John Poore, R.N., was born at Andover on 23rd September, 1843; he was educated at the Royal Naval School, New Cross, and University College, London, and at the hospital he was a favourite pupil of Sir William Jenner. He became a member of the Royal College of Surgeons in 1866, in which year he was surgeon to the Great Eastern Steamship during the laying of the Atlantic cable. He was member of the Royal College of Physicians in 1870, and a Fellow in 1877. He was medical attendant to the late Prince Leopold, Duke of Albany, 1870-71, and assistant physician to University College Hospital, becoming full physician in 1876. He was widely known as an authority on sanitary subjects, and was General Secretary of the International Congress of Hygiene and Demography, 1891. His strenuous condemnation of all systems of sewerage which carried away from the soil matters capable of enriching it was expressed in various books, pamphlets and addresses, and the principles which guided him were practically illustrated on his property at Andover. He succeeded Professor Erichsen as inspector under the Vivisection Acts, and published several works and papers on strictly professional subjects, one of these being a Treatise on Medical Jurisprudence.

GENERAL NOTES.

PERSIA AND COTTON CULTIVATION.—Referring to an article that appeared in the last number of the *Journal* upon the world's cotton supply, the following remarks taken from Mr Consul-General Preece's report on trade in Persia (just issued) may be read with interest. The Consul-General writes:—Owing to the advent of Russian buyers the amount of cotton floated in Ispahan and its environs has of late years steadily increased in spite of the fact that the cotton, owing to the poverty of the ground and want of renewal of seed, has equally steadily deteriorated. In days gone by Ispahan cotton had a very high place in the estimation of the people of the East, but that is quite lost. The staple now is short and brittle, all the same it has a ready sale for export to Russia, and also to a smaller extent to Bombay, where it is mixed with Indian cotton for use in the home market. The amount exported last year to Russia was 5,000,000 lbs., and to Bombay over 400,000 lbs. Since the war broke out in the Far East there have been practically no purchases for Russia, yet this year's crop is heavier than that of the previous one. The staple of Ispahan cotton is too short for Lancashire requirements even supposing that the cotton could be cultivated in sufficient quantities to make it worth while to import it, but this would not prove remunerative enough until easier and cheaper means of communication were found. In the valley of the Karum if only proper irrigation works are undertaken, good cotton could be cultivated for the home market to a very large extent.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock:—

DECEMBER 7.—"The International Exhibition at St. Louis." By WALTER FRANCIS REID, F.I.C., F.C.S. DR. BOVERTON REDWOOD, F.R.S.E., will preside.

DECEMBER 14.—"The Patent Laws." By CHAS. D. ABEL.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

DECEMBER 8.—"Burma." By SIR FREDERIC FRYER, K.C.S.I. In consequence of the lamented death of the Earl of Hardwicke, announced to preside, SIR CHARLES H. T. CROSTHWAITE, K.C.S.I., Member of the Council of India, has kindly consented to take the chair.

APPLIED ART SECTION.

Tuesdays, at 4.30 or 8 o'clock:—

DECEMBER 20 (8 p.m.).—"Street Architecture." By THOMAS GRAHAM JACKSON, R.A. DR. G. B. LONGSTAFF, L.C.C., will preside.

Papers for Meetings after Christmas:—

"The Navigation of the Nile." By SIR WILLIAM H. PREECE, K.C.B., F.R.S.

"The Protection of Buildings from Lightning." By KILLINGWORTH HEDGES, M.Inst.C.E.

"The Present Aspect of the Fiscal Question." By SIR CHARLES MALCOLM KENNEDY, K.C.M.G., C.B.

"British Woodlands." By The RIGHT HON. SIR HERBERT MAXWELL, Bart., M.P.

"The Supply of Electricity." By JAMES NELSON SHOOLBRED, B.A., M.Inst.C.E.

"Time Development in Photography, and Modern Mechanical Methods of carrying it out." By R. CHILD BAYLEY.

"London Electric Railways." By the HON. ROBERT P. PORTER.

"Lake Baikal and its Connection with the Great Siberian Railway." By ARTHUR GULSTAN.

"The True Musical Pitch of Notes we See and Sounds we Hear." By JOHN E. BORLAND.

"Wireless Telegraphy and War Correspondence." By CAPTAIN LIONEL JAMES.

"The British Art Section of the St. Louis Exhibition." By ISIDORE SPIELMANN.

"Popular Jewelry." By MONSIEUR LALIQUE (Paris). (*Applied Art Section.*)

"The Cape to Cairo Railway." By SIR CHARLES H. T. METCALFE, Bart., M.Inst.C.E. (*Colonial Section.*)

CANTOR LECTURES.

Monday evenings, at 8 o'clock:—

DAVID JAMES BLAIKLEY, "Musical Wind Instruments." Four Lectures (with musical illustrations).

LECTURE II.—DECEMBER 5.—*Brass Instruments.* —Primitive instruments from horns and shells—Harmonic scale—Development into bugle and trumpet types—natural horns and trumpets—Introduction of slides, keys, and valves.

JUVENILE LECTURES.

Two lectures suitable for a juvenile audience will be delivered on Wednesday evenings, January 4 and 11, 1905, at Five o'clock, by Mr. CARMICHAEL THOMAS, Treasurer of the Society, on "The Production of an Illustrated Newspaper."

MEETINGS FOR THE ENSUING WEEK.

MONDAY, DEC. 5...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lectures.) Mr. David James Blaikley, "Musical Wind Instruments." (Lecture II.—Brass Instruments.)

Farmers' Club, 2 Whitehall-court, S.W., 4 p.m. Mr. Thomas F. Plowman, "The Policy of the Show-yard and its Administrative Methods."

Royal Institution, Albemarle-street, W., 5 p.m. General Monthly Meeting.

Engineers, in the Theatre of the United Service Institution, Whitehall, S.W., 7½ p.m. Mr. William Edward Storey, "Condensing Machinery."

Chemical Industry (London Section), Burlington-house, W., 8 p.m. 1. Dr. E. Divers (*a*) "Raschig's Theory of the Lead Chamber Process;" (*b*) "Theory of the Action of Metals on Nitric Acid." 2. Mr. Llewellyn J. Davies, "A Rapid and Accurate Method for the Estimation of Phosphorus in Iron Ores." 3. Mr. C. S. Stanford Webster, "Fluorescope for Comparing Substances under the Influence of Radium Rays."

British Architects, 9, Conduit-street, W., 8 p.m.

Camera Club, Charing-cross-road, W.C., 8½ p.m.

Victoria Institute, 8 Adelphi-terrace, W.C., 4½ p.m. Rev. F. Storrs Turner, "The Right Way in Psychology."

London Institution, Finsbury-circus, E.C., 5 p.m. Mr. Arthur Diósy, "The probable results of the Russo-Japanese Conflict as affecting Commerce in the Far East."

TUESDAY, DEC. 6...Civil Engineers, 25, Great George-street, S.W., 8 p.m. 1. Discussion on Mr. John Francis Cleverton Snell's paper, "Distribution of Electrical Energy." 2. Messrs. Arthur Wood-Hill and Edward Davy Pain, "The Construction of a Concrete Railway Viaduct."

Pathological, 20, Hanover-square, W., 8½ p.m.

Anthropological, 3, Hanover-square, W., 8½ p.m.

Colonial Inst., Whitehall-rooms, Whitehall-place, S.W., 8 p.m.

Pharmaceutical, 17, Bloomsbury-square, W.C., 8 p.m.

WEDNESDAY, DEC. 7...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. Walter Francis Reid, "The International Exhibition at St. Louis, U.S.A."

Geological, Burlington-house, W., 8 p.m.

United Service Institution, Whitehall, S.W., 3 p.m. Mr. J. Moore, "Horses of different Countries and Supply, with relation to Military Services."

Entomological, 11, Chandos-street, W., 8 p.m.

Royal Archæological Institution, 20, Hanover-square, W., 4 p.m. 1. Mr. J. Hilton, "The Pfahlgraben and Saalburg, in Germany." 2. Mr. Philip H. Johnston, "Mural Paintings recently Discovered in Trotton Church, Sussex, &c."

Obstetrical, 20, Hanover-square, W., 8 p.m.

Central Chamber of Agriculture (at the HOUSE OF THE SOCIETY OF ARTS), 11 a.m.

THURSDAY, DEC. 8...SOCIETY OF ARTS, John-street, Adelphi, W.C., 4½ p.m. (Indian Section.) Sir Frederic W. R. Fryer, "Burma."

Royal, Burlington-house, Piccadilly, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

London Institution, Finsbury-circus, E.C., 6 p.m. The Hon. Charles S. Rolls, "The Development of Motor Traffic."

Civil and Mechanical Engineers, Caxton-hall, Westminster, S.W., 8 p.m. Mr. H. E. Bellamy "Notes on Portland Cement."

Electrical Engineers, 25, Great George-street, S.W., 8 p.m. 1. Discussion on papers by Prof. H. S. Hele-Shaw, Dr. A. Hay, and Mr. F. H. Powell, "Hydrodynamical and Electromagnetic Investigations regarding the Magnetic-Flux Distribution in Toothed Core Armatures." 2. Mr. G. F. C. Searle, "Studies in Magnetic Testing."

Mathematical, 22, Albemarle-street, W., 5½ p.m.

Camera Club, Charing-cross-road, W.C., 8½ p.m.

FRIDAY, DEC. 9...Astronomical, Burlington-house, W., 8 p.m.

Architectural Association, 18, Tufton-street, S.W., 7½ p.m. Mr. T. Raffles Davison, "Some Architectural Reflections."

Clinical, 20, Hanover-square, W., 8½ p.m.

Physical, in the Physical Laboratory of the Central Technical College, Exhibition-road, S.W., 8 p.m. 1. Prof. S. P. Thompson, "A Rapid Method of Approximate Harmonic Analysis." 2. Mr. W. Duddell, "A High-Frequency Alternator." 3. Exhibition of Experiments to show the retardation of the signalling current on 3,500 miles of the Pacific Cable between Vancouver and Fanning Island. 4. Exhibit of Ayrton-Mather Galvanometers, Universal Shunts, and Electrostatic Instruments."

Journal of the Society of Arts.

No. 2,716. VOL. LIII.

FRIDAY, DECEMBER 9, 1904.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

NOTICES.

NEXT WEEK.

MONDAY, DECEMBER 12, 8 p.m. (Cantor Lecture.) D. J. BLAIKLEY, "Musical Wind Instruments." (Lecture III. Reed instruments, with musical illustrations.)

WEDNESDAY, DECEMBER 14, 8 p.m. (Ordinary Meeting.) CHARLES D. ABEL, "The Patent Laws."

Further details of the Society's meetings will be found at the end of this number.

JUVENILE LECTURES.

The usual short course of lectures adapted for a juvenile audience will be delivered on Wednesday afternoons, January 4th and 11th, at 5 o'clock, by Mr. CARMICHAEL THOMAS, Treasurer of the Society, on "The Production of an Illustrated Newspaper."

Each member is entitled to a ticket admitting two children and an adult.

A sufficient number of tickets to fill the room will be issued to members in the order in which applications are received.

Members who desire tickets for the course are requested to apply for them at once.

INDIAN SECTION COMMITTEE.

A meeting of the committee of the Indian Section was held on Thursday afternoon, 1st inst. Present:—Sir William Lee-Warner, K.C.S.I. (in the chair), J. A. Baines, C.S.I., Sir Stewart C. Bayley, K.C.S.I., T. J. Bennett, C.I.E., Dr. H. M. Birdwood, C.S.I., Major-General Sir Owen Tudor Burne, G.C.I.E., K.C.S.I., F. C. Danvers, J. F. Finlay, C.S.I., Colonel Sir Thomas Holdich, R.E., K.C.M.G., C.B., Alexander Rogers, Sir Edward Sassoon, Bart., M.P., Carmichael Thomas, W. Martin Wood, with Sir Henry Trueman Wood, Secretary of the Society, and S. Digby, Secretary of the Section. The arrangements for the session were considered.

CANTOR LECTURES.

Mr. D. J. BLAIKLEY delivered the second lecture of his course on "Musical Wind Instruments," on Monday evening, 5th inst.

The lectures will be printed in the *Journal* during the Christmas recess.

INDIAN SECTION.

Thursday afternoon, December 8th. Sir CHARLES H. T. CROSTHWAITE, K.C.S.I., Member of Council for India, in the chair.

The paper read was "Burma," by Sir FREDERIC FRYER, K.C.S.I.

The paper and report of the discussion will be published in a future number of the *Journal*.

PROCEEDINGS OF THE SOCIETY.

FOURTH ORDINARY MEETING.

Wednesday, December 7, 1904; DR. BOVERTON REDWOOD, F.R.S.E., Member of the Council, in the chair.

The following candidates were proposed for election as members of the Society:—

Dale, Hylton William, 8, Chalcot-gardens, Belsize-park, N.W.

Ertz, Edward Frederick, R.B.A., Polperro, Cornwall.

Fletcher-Watson, P., R.B.A., Ashleigh, Paignton, South Devon.

Lee, Sydney, 6, The Studios, Holland-park-road, Kensington, W.

Lim Chin Tsong, 47, China-street, Rangoon, Burma.

Stell, Samuel Fenton, F.C.S., 25, Henry-street, Keighley, Yorkshire.

Townend, Frederick Bedborough, 11, Queen Victoria-street, E.C., and Brentwood, Essex.

The following candidates were balloted for and duly elected members of the Society:—

Heraje, Pandoorung, Agar Bazar, Dadar, Bombay, India.

Hnyin, Tha, B.A., F.C.S., 13, Ladbroke-road, W.

Ince, Robert Self, 24, Deerbrook-road, Herne-hill, S.E.

Jagonnath, Ganpat, Lady Jumshedjee-road, Dadar, Bombay, India.

Jordan, Albert Edward, A.M.I.Mech.E., 6, High-road, Nungumbaukum, Madras, India.

Moorcroft, Harold, Marsh-parade, Wolstanton, Staffs.

Townsend, W. G. Paulson, 12, Clifford's-inn, Fleet-street, E.C.

Wheatley, William Humphrey, 40, Chancery-lane, W.C.

The CHAIRMAN said:—To many of you the reader of the paper is already known personally, to many more by repute, but even Mr. Reid's best friends are probably unaware of the extent and important character of the work which he has recently carried out as juror at St. Louis under trying climatic conditions. Mr. Reid went to St. Louis as one of the two representatives of Great Britain nominated by the Royal Commission to serve on the International Jury for Chemical and Pharmaceutical Arts, his colleague being Mr. H. J. Helm. In the first instance the author and Mr. Helm were members of the Group Jury dealing with Chemical and Pharmaceutical Arts, and Mr. Reid has borne testimony to the great assistance given and excellent work accomplished by his colleague. Mr. Reid was then successively appointed vice-chairman for Group 23, for Group 22, for Liberal Arts, for Horticulture, and for Aeronautics; also member of the Superior Jury and Secretary of the Appeal Committee for Horticulture, Agriculture, and Physical Culture. I have always recognised in Mr. Reid the possession of encyclopædic knowledge, but I am really surprised that with these multifarious demands upon his energies, in a climate which was at the time subtropical, he returned to this country in mental and physical soundness, especially when we remember that our American cousins are not lacking in hospitality, so that I have no doubt he was often called upon to serve on a gastronomic jury at the close of the day's work. To all but those familiar with exhibition jury work these duties, though manifold, may appear simple if the executant is possessed of the necessary knowledge of the products with which he and his colleagues have to deal, but, in effect, there is no work demanding in addition greater discretion, judgment, and general diplomatic ability. Theoretically, the duty of a jury is to form a judgment of the respective and relative merits of the exhibits, and to recommend awards accordingly, but there are many other matters, such as the importance and originality of the processes by which the products have been obtained, and the difficulties which have had to be overcome in achieving commercial success, which have to be taken into account. Finally, in the case of an international jury there are the inevitable national rivalries and jealousies to be dealt with, and it is then that diplomatic ability becomes an essential factor. At this stage each member of the jury necessarily becomes largely an advocate, at any rate in the sense that it devolves upon him to see that his foreign colleagues fully appreciate the special merits of the exhibits contributed by the country which he represents. In discharging these delicate duties Mr. Reid's exceptional linguistic abilities proved most valuable, indeed, so essential that he was called upon to fill the honorary office of interpreter in general, which certainly did not fall within the scope of the work of a juryman. However good may be our British exhibits, the numerous contributors would certainly not have obtained for them the high awards of which a list has been published if Mr. Reid had not discharged with conspicuous ability the varied, difficult, and highly responsible duties to which I have alluded.

The paper read was—

THE INTERNATIONAL EXHIBITION AT ST. LOUIS, U.S.A.

BY WALTER FRANCIS REID, F.I.C., F.C.S.

When the Society of Arts, in 1851, initiated the first great international exhibition, few can have anticipated that the movement would have been accepted by all civilised nations so rapidly as has been the case. In 1850, H.R.H. The Prince Albert said:—

"Nobody who has paid any attention to the particular features of our present era will doubt for a moment that we are living at a period of most wonderful transition, which tends rapidly to the accomplishment of that great end to which, indeed, all history points—the realisation of the unity of mankind."

Those remarks are even more applicable now than they were half a century ago, and there are indications that the seed sown by our late illustrious and far-seeing President is producing fruit. It is not a casual coincidence that the year of the great St. Louis Exhibition should witness the signature of treaties of arbitration between most civilised nations, and that disputes which, but a few years ago, would have meant war with all its horrors and irreparable losses to both victor and vanquished, should now be settled calmly and peacably.

As one of the 20,000,000 visitors who passed through the gates that were closed last Thursday, I will endeavour to give you a brief account of the buildings and their contents. The general aspects of the St. Louis Exhibition have been so fully dealt with in the paper read

before this Society in November, 1903, by Mr. G. F. Parker, that my introductory remarks may be brief. As most of you are aware, the "Louisiana Purchase Exposition" was held to commemorate the centenary of the purchase in 1803 by the United States from France of the territory of Louisiana. The city of St. Louis was chosen as the site, and those who have lived among its 600,000 courteous and hospitable inhabitants will admit that the selection was a wise one. An area of 1,240 acres about six miles from the Mississippi front of the city was set apart for, but not completely occupied by, the exhibition buildings. It is a great mistake to devote too large an area to an exhibition. Most of the visitors have but a short time to stay, and it is extremely disappointing to them to be obliged to waste valuable time in traversing considerable distances between the buildings. The means of communication between the buildings were very defective, for although there was an intramural electric railway, about eight miles in length, it did not serve many of the chief buildings, and was interrupted at the most important spot. One of the chief lessons to be learnt from St. Louis, is that there are limits to the dimensions of an exhibition beyond which it is not advisable to go. None but a trained pedestrian could hope to see the whole of the exhibition within a reasonable time. Let us hope that the next "World's Fair" may be concentrated within a more reasonable area.

But there are other, and more important, lessons that may be learnt from this great concourse of nations. Probably the most useful feature was the great number of international congresses held at St. Louis. These numbered about 300, and there can have been few departments of human work or thought that were not represented from all parts of the globe. Innumerable friendships have been made among the members of these congresses and of the various juries, and the amicable relations thus established cannot fail to have a favourable influence upon the intercourse of the nations whom they represented.

You will probably wish to know whether there may not be some special lessons which Great Britain has to learn from the nations with whom she has been engaged in friendly rivalry. I think there are, especially from one point of view, which is of great importance if we are to maintain our proper industrial and commercial position. Mr. F. J. V. Skiff, the director of exhibits at St. Louis, and who also gained great experience at Chicago, rightly says:—"The creation of expositions has become a profession." Our chief competitors for the world's commerce have long since realised that in the contests of peace even more than in war it is necessary to be prepared beforehand, and they have organised permanent departments for exhibition work, thus securing continuity of experience and ideas. We alone, the originators of international exhibitions, are content to leave these matters to chance, and when an exhibition is announced, we tardily collect the best men we can find, among whom are fortunately some who have had previous exhibition experience. It is true that we have done well at St. Louis, but this is due to the zeal and ability of those who represent us rather than to a system which leaves so much to be done at the last moment. A careful observer could not fail to notice many points in the organisation of other nations that we should do well to copy, but we have no machinery for doing so. The Society of Arts was formerly the body that kept up the continuity of ideas between the various exhibitions, but these undertakings are now so vast as to be beyond the powers of any single society. I see no reason, however, why a joint committee of this and other societies should not be formed to collect the experience gained at St. Louis, and to utilise it as soon as another international exhibition is projected.

The construction of the buildings in a great exhibition and the arrangement of the exhibits in them are matters of primary importance, and must to a great extent depend upon the funds available. The financial balance-sheet of the St. Louis Exhibition has not yet been published, but it is known that about £4,000,000 was spent in the first instance. It will suffice for the present if I give you the approximate cost of the chief buildings as we pass them under review. If the enterprise has not been a financial success for its promoters it has undoubtedly benefited the country, and from that point of view the money has been well spent. Of course the benefit to the town of St. Louis must have been very considerable. In the building of the exhibition much skill and ability have been shown. The great majority of the structures consist of a wood framework built approximately to the shape required. Upon the wood, expanded steel sheets are nailed, and the surface is finished off with plaster. The plaster adheres well to the expanded metal, into the interstices

of which it penetrates. In wet weather, however, considerable masses of plaster fell from the horticultural and agricultural buildings. Perhaps the incessant cannonade from the representations of the Boer War and the Battle of Santiago contributed towards this premature disintegration of the buildings.

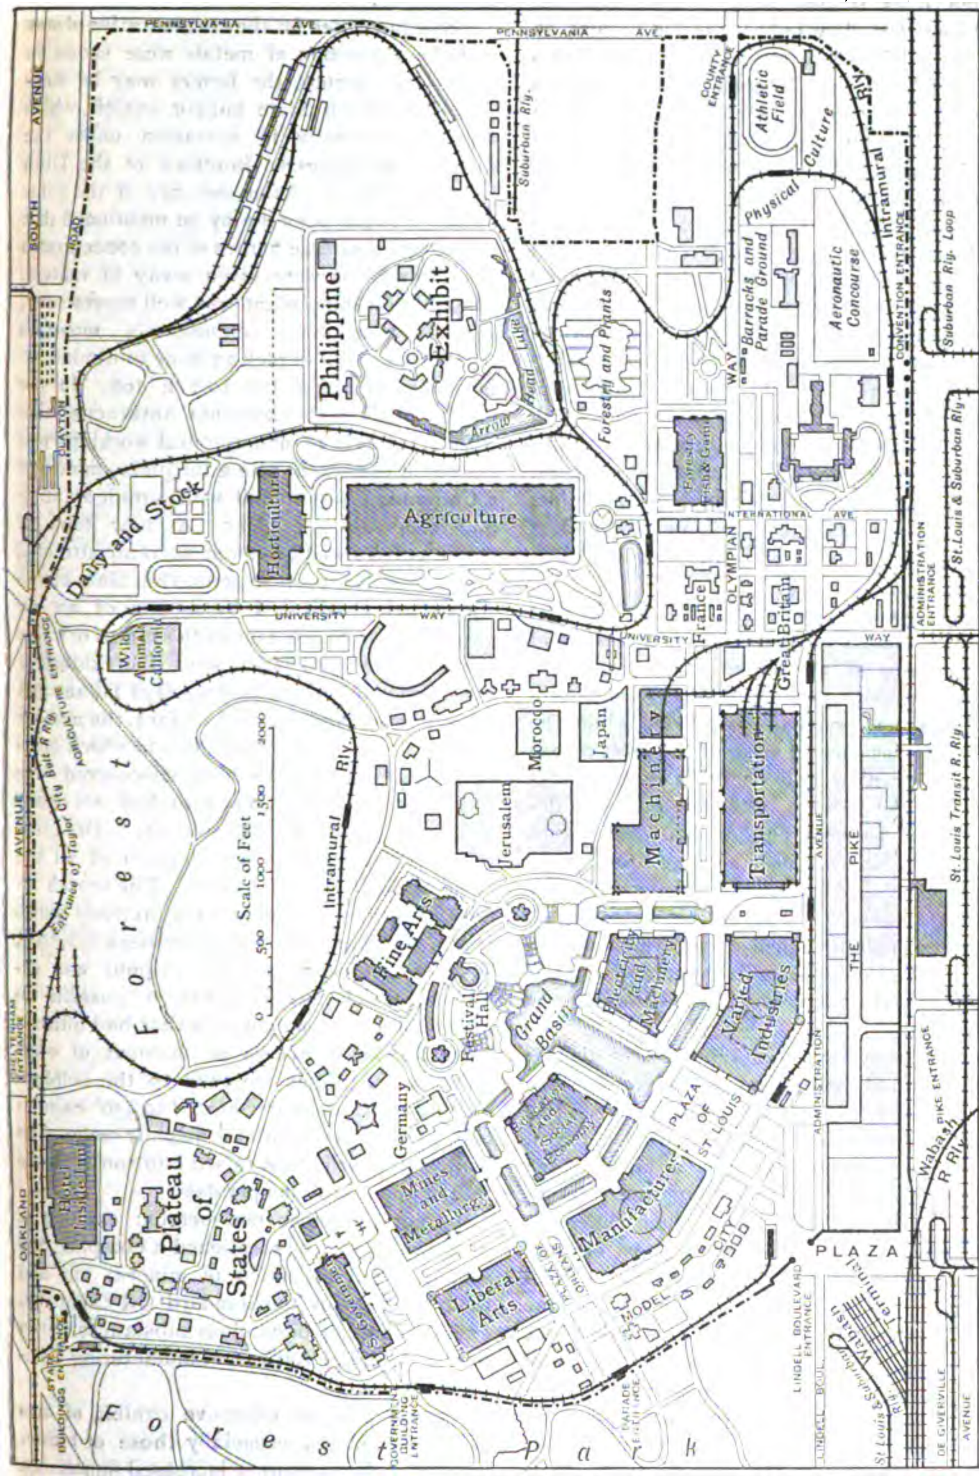
Such structures are necessarily highly inflammable, and stringent precautions had to be taken against the introduction of naked lights into the buildings. Even flash-lights for photographic purposes were forbidden. It is probably owing to the excellent arrangements made in this respect that serious conflagrations have been avoided.

In the time at our disposal we can only examine about a dozen of these buildings and but very few of the thousands of exhibits. As regards the latter, I have endeavoured to select those which are of general interest or which have some special reference to Great Britain.

We will begin with the *United States Government Building*. This occupies one of the best situations on the whole site, on sloping ground facing the Liberal Arts and Mines and Metallurgy palaces. It contains the chief exhibits of the United States Government, and its cost was estimated at about £26,000. It is about 925 feet long and 250 feet broad, covering an area of 9·1 acres. The building contains the fullest collection of Government exhibits that has ever been shown. Especially noteworthy are the exhibits of the army, with a complete set of cartridge-making machinery in operation; the post-office, including a complete set of United States stamps and a good series of models showing the methods of carrying mails, from the Esquimaux dog sledges of Alaska to the pneumatic postal tube so extensively used in New York and other large cities. The navy is represented by a full-size model of a war-ship and a tank containing stationary mines. One of the most attractive displays is that of the Smithsonian Institution, containing a large and well-selected collection of natural history, specimens ranging from gigantic meteorites to restorations of some of the colossal saurians recently discovered by American paleontologists. The Bureaux of Animal and Plant Industry and the Department of Entomology have also interesting exhibits illustrative of the work carried on under their auspices. The tax-payer of the United States who visits this building can form a very good idea of the way in which much of the public money is spent and the object-lesson is one that might with advantage be repeated in this country.

Facing the east end of the United States Government Building is the *Palace of Liberal Arts*, which is 750 feet long, and 525 feet wide, covering an area of about 9 acres. Its cost was £95,000. Exhibits comprised in groups 15 to 27 were mainly contained in this building; but, except in the case of Great Britain, this classification was not rigidly adhered to, with the result that much time was wasted by the juries in going from one building to another. The arrangement of exhibits is always a difficulty; but for the visitor who wishes to study any special subject it is undoubtedly better to have objects of the same kind under one roof. This may, however, in many cases render the supervision of the exhibits by the agents of the various countries or exhibitors less efficient. It is difficult to estimate in advance how much space may be required in each building, and it may sometimes be advisable to devote surplus space originally assigned to one group to the relief of another that may be over-crowded. Although Great Britain did not rank first as regards the number of exhibits in this building, yet the quality, as indicated by the number and nature of the awards, was excellent. The preparatory work done by our Royal Commission and the full particulars which had been obtained from the exhibitors for the use of the jury ensured a full appreciation of the merits of each exhibit.

First, both as regards the number of exhibitors and of awards, comes Group 23, Chemical and Pharmaceutical Arts. The sub-committee for this group, under the chairmanship of Dr. Boverton Redwood, our chairman this evening, had secured so high a standard of excellence in the exhibits that 112 exhibitors obtained 100 prizes. Most of our large chemical and pharmaceutical manufacturers were well represented, and the most careful comparison with other nations failed to show any trace of that decadence in our chemical industry that is the favourite stalking-horse of some educational enthusiasts. After an exhaustive examination of all the chemical exhibits Dr. E. H. Keiser, the distinguished professor of chemistry at Washington University, adopted the descriptive catalogue prepared by our Royal Commission as an advanced text-book of technical chemistry, and brought his students to the British exhibits as up-to-date samples of chemical products. It is doubtless true that other



GROUND PLAN OF THE ST. LOUIS EXHIBITION, 1904.

nations surpass us in certain articles such as aniline dyes or synthetic drugs; but the tendency of modern industry is for nations as well as individuals to specialise, and it by no means follows that, because other countries may be doing a remunerative business in articles that we once produced, we have lost the business. Our capitalists and workers may have found even more remunerative outlets for their abilities, and it is only where they are hampered by unfair fiscal restrictions and patent laws that redress is needed. Germany had an excellent chemical exhibit, both of products and apparatus, which was housed in the Palace of Electricity, and included a large collective exhibit of the goods of numerous chemical manufacturers. France showed a fine selection of pharmaceutical preparations and perfumery arranged in artistic show-cases. The United States included among her exhibits the finest collection of chemicals exhibited at St. Louis by one firm—the Mallinckrodt Chemical Works.

The Chinese Government had, for the first time, an official collection of materials and drugs, many of the latter unknown to the Western world. In photography Great Britain exhibited an excellent collection, while the United States showed some of the most recent forms of printing machinery in daily operation. In the Liberal Arts Building were delivered the lectures on liquid air and liquid hydrogen which had been arranged for by our Royal Commission, and which attracted numerous audiences. The machinery by which hydrogen could be liquefied and even solidified was installed in a special building and aroused much interest among scientific visitors to the exhibition.

Immediately facing the Liberal Arts Palace and separated from it by a sunken garden was the *Palace of Mines and Metallurgy*. The building has a floor area of about 9 acres, but the department includes a further area of 12 acres occupied by separate mining exhibits in the mining gulch. The architecture of this building is probably the most original of any in the exhibition, and the cost has been given as £99,600. Its contents show the boundless mineral wealth of the United States, and the system of having separate sections for each State has produced a healthy rivalry calculated to show off those resources to the best advantage. Among the British exhibits, an interesting collection of minerals and stones by the mining department of the Home Office attracted much attention, and the Iron and Steel Institute showed a valuable collection of literature.

Many processes for the concentration of ores and the extraction of metals were shown in operation. Among the former may be mentioned the Utah State mining exhibit, which was shown daily in operation under the direction of Professor Bradford of the Utah School of Mines. As an instance of the value attached to publicity it may be mentioned that 20,000 small sample bottles of the concentrates from this plant were given away to visitors. The rock-crushing plant was well represented, varying from huge omnivorous monsters crushing 500 tons of rock an hour to diminutive machines crushing but half a ton. In the mining gulch a Pennsylvania anthracite mine with 1,750 feet of underground workings was shown in operation, also a turquoise mine and a Californian stamp mill with amalgamating and concentrating plant. A new form of stamp mill worked by compressed air attracted much attention from experts, the blow of the stamp being adjusted by means of an air cushion so as to avoid injury to stamps or frame should the material vary in size. The exhibits of gems and polished opalised wood of Tiffany and Co. were generally admired, in fact, the number of localities in the United States in which gems of various kinds have been discovered was quite a revelation to those who had not made a special study of the subject. Of great scientific interest was a collection of all the radio-active minerals known. The search for new sources of radium is being actively prosecuted, and many new finds have been reported. A new method of mining sulphur was exhibited, which has rendered it possible to utilise the Louisiana deposits that had hitherto been difficult of access on account of overlying sands. Pipes are sunk to the sulphur-bearing rock, and water heated to 330° Fahrenheit is forced down until the sulphur melts. The molten sulphur is then raised into tanks at the rate of about 500 tons per day.

Among the other non-metallic exhibits of importance, may be mentioned a complete and well-arranged collection of mineral oils and their products by the Standard Oil Company, and a number of bituminous substances shown by the Trinidad Asphalt Manufacturing Company.

Canada had an extensive exhibit of ores of various kinds, especially those of nickel, which metal is acquiring increased importance from its use for naval and military purposes.

The Bethlehem Steel Company showed a

large quantity of war material, including a full-size model of a 12-inch gun and turret, together with a selection of armour-plates and guns of various dimensions.

Under the supervision of the chief of the Department of Mines and Metallurgy, Dr. J. A. Holmes, one of the most complete series of coal tests that have ever been undertaken is being carried out. Congress has voted a sum of £12,000 to defray the cost of the work; but the apparatus and coal are furnished by the owners free of cost. Each test is made with a car load of coal, which is loaded at the mine under the supervision of an official who takes the samples required for chemical analysis from the face of the seam. The experiments include producing steam, generating gas, coking in coke ovens, briquetting and washing. Careful chemical and practical tests are made not only of the coal itself but also of the various products obtained. The results of so complete a series of investigations will be of great use not only to the United States but to coal users throughout the world. A description of this department would not be complete without a reference to the colossal iron statue of Vulcan, representing the iron industry of Alabama. The height of the statue is 50 feet and the weight about 67 tons.

The next building is that of *Education and Social Economy*, which also covers an area of about nine acres. It is estimated to have cost about £63,879. Although so large a building has been set apart for educational purposes it must not be forgotten that the whole exhibition is an educational exhibit of the highest order. No one could visit it even for an hour without acquiring some useful information or seeing something he had never seen before. In these days of rapid progress the education of the adult is of even more importance than that of the child, and there is no easier way of acquiring information than a visit to a great exhibition. It is to be feared that many of those occupying responsible positions in this country do not devote much of their leisure time to keeping their knowledge up-to-date. Those who visit exhibitions frequently, must have noticed many cases in which old-established firms are hopelessly behind the times in technical knowledge.

The British educational exhibit is quite up to date and probably affords the best object-lesson that has ever been brought together of the variety of educational facilities available in this country. Not only has the Education Committee of the Royal Commission been very successful in obtaining a good collection of exhibits from all the British universities and other educational institutions, but the best possible use has been made of that collection by Capt. P. H. Atkin, the energetic and courteous representative of that Committee in St. Louis. It is true that our exhibit does not contain such large collections of apparatus as are to be found in the German section; but it should be borne in mind that the greater part of this apparatus is not new, and the quantity transported to and set up at St. Louis is chiefly a question of the funds available for that purpose. The German educational exhibit is, however, as might have been expected, of high character, and the hand-books issued on educational and social subjects are interesting reading.

The United States are well represented, a grant of £20,000 having been voted by Congress for exhibits of the mechanical and agricultural experiment stations and colleges. There can be no doubt that the agricultural experiment stations have had a most beneficial and far-reaching effect upon the agriculture of the country, and have added greatly to its prosperity.

The *Palace of Manufactures* and the *Palace of Varied Industries* contain exhibits so closely allied that they may well be taken together. Each building is 1,200 feet long and 525 feet broad, encloses 14 acres, and cost about £130,000. No doubt, chiefly for fiscal reasons, British manufacturers were not so strongly represented as might have been the case in a country with a lower import tariff. Among those industries that had good exhibits may be mentioned decorative and fixed furniture, ceramics, and lace and embroidery. The Italian sculpture attracted much attention, and the French costume and millinery displays were generally surrounded by an admiring crowd. Japanese industry was well represented, especially in silks, ceramics, and art metal work. When war was declared between Russia and Japan, the former country abandoned the idea of taking part in the exhibition, and relinquished the space reserved for her. Japan at once took it up, and has not only filled it but filled it well. To those who have watched the development of Japanese industry it must be evident that the tendency to imitate European goods is increasing very rapidly; sometimes the imitation includes the label or trade mark.

Among the numerous industries shown in operation the rearing of silkworms and production of silk were very popular. The well-known

St. Louis firm of Mermod and Jaccard showed in active operation all the processes of enamelling as applied to jewellery, and Messrs. Krupp exhibited a new process for the embossing of gold and silver ware. In this new industry a powerful hydraulic press weighing 120 tons is used. The design is engraved on the inside of a hollow steel die made in four pieces, and into this die the plain silver vessel is placed. Inside the silver vessel an india-rubber lining is inserted, and the air between the two materials exhausted. The whole is then placed in the cylinder of the hydraulic press, and a pressure of about 85,000 lbs. per square inch applied. Under this enormous pressure the silver becomes plastic, and gives a beautiful reproduction of the most minute details of the die.

Many other industries were represented in actual operation, especially the manufacture of leather, boots, hats, textiles, &c. Forty nations sent exhibits representing 900 industries, and it would require at least a week to give a description of the contents of these two buildings. Before leaving the palace of varied industries we will pass through some of a large number of rooms in the German section which present many features of interest. Each room, together with its furniture, has been designed by one architect, thus securing uniformity of design. Dr. Lewald, Imperial Commissioner-General for Germany, has been kind enough to send me some special photographs of these rooms which will no doubt interest you.

The Palace of Electricity covers about 9 acres and its cost is stated to have been £80,000. There can be no doubt that the United States occupy the first position as regards general electrical appliances, but Great Britain has the best collection of testing, measuring, and recording instruments, and her exhibitors obtained awards worthy of the country of Faraday and Kelvin. One of the most noticeable features of the St. Louis Exhibition was the extensive use of electricity for a variety of purposes. It was the chief means for the transmission of power and practically the whole place was lighted by electricity. About 500,000 incandescent lamps were used for the illumination of the grounds and buildings. In metallurgy electricity has supplied us with the means of obtaining results that were formerly beyond our reach, and for many industrial and even domestic purposes it has become indispensable. Progress was specially marked in motors for street railways, and an experimental track was provided for carrying out practical tests with electric cars. One of the biggest searchlights ever constructed was in operation; it weighed four tons, and its light was estimated at 5,250,000 candle-power. Several systems of wireless telegraphy were exhibited and worked, and a wireless telephone was in use over short distances. The extent of the illumination of the grounds and buildings exceeded all previous displays, and the effect was magnificent. In many cases the lights themselves were hidden behind columns and the façades of the buildings were lit up by a soft, reflected light which was extremely effective. The direct illumination of the cascades by means of powerful searchlights from adjoining buildings was not so successful as incandescent lamps placed behind the falling water.

In connection with light the exhibit of the Finsen light must not be forgotten. Much electro-therapeutic apparatus was shown as well as the most recent forms of X-ray tubes for diagnostic purposes.

An interesting historical collection of electric appliances was sent by F. A. Edison, whose new storage battery attracted many visitors.

So intimately connected are power and electricity in modern practice that to study the production of the latter we must pass out to the *Palace of Machinery*, the dimensions of which were 1,000 feet by 525 feet, while the cost was £93,391.

Considering that a force of 50,000 horse-power was being generated in this building, the absence of noise was perhaps the most striking feature. Although much of the machinery rotated with great rapidity, it did so quietly, while at the same time it conveyed to the observer a sensation of concentrated energy difficult to define. An ordinary steam fire-engine in our streets makes more noise than these motors that were pumping 90,000 gallons per minute to a height of 100 feet. The general impression derived from the exhibits in this building is that for the production of electricity on the large scale steam turbines are rapidly supplanting reciprocating engines. The use of producer gas may give a fresh lease of life to the latter; but even here the turbine principle may ultimately be adapted. The lubrication difficulties appear to have been surmounted in the case of the steam turbine. The Curtis steam turbine, for instance, weighing 70 tons, and generating 2,000 horse-power, can be easily moved by the hand, and if the steam be cut off while the

turbine is working at 1,500 revolutions per minute, it will continue to revolve for three hours. The moving parts are practically supported upon a film of oil at a pressure of 600 lb. per square inch. Large as they are, the steam turbine generators exhibited were small compared with others under construction elsewhere. The small space required by steam turbines may be judged from the fact that a 600 horse-power Westinghouse-Parsons turbine measures 18 feet 6 inches in length, 4 feet 6 inches in width, and 7 feet 6 inches in height.

This building also contained a fine collection of machine tools of various kinds, varying in size from a 170-ton boring and turning machine down to delicate watch-making plant, working with an accuracy of one ten-thousandth part of an inch.

A veneer-cutting machine which converted logs of wood into gigantic shavings of the required thickness attracted many of the visitors. The supply of steam for the machinery building passed through a tunnel of 56 square feet section from the *Steam, Gas, and Fuel Building*, also called the *Power House*. This was a comparatively small building, being 320 feet by 320 feet, and differed from the majority of the buildings in being of fireproof construction. The daily fuel consumption was over 400 tons, the coal being brought direct from the mines in 170 fifty-ton coal cars. The coal was bituminous and at times dense clouds of smoke were produced, obscuring the adjoining buildings. Nearly the whole of the stoking was mechanical; from the time the coal was tipped from the waggons until the clinkers and ashes were removed in trucks no handling was required. All the boilers were of the water-tube type, of which several varieties were at work. A battery of 16 Babcock and Wilcox boilers supplied 6,400 horse-power, while the same number of Aultman and Taylor boilers of two different sizes produced steam equal to 7,200 horse-power. With regard to the competition between steam and gas-engines as sources of power, it should be mentioned that, owing to questions of insurance the latter were not so well represented as their importance would have justified.

Facing the Power House is the *Transportation Palace*, which is the largest of this group of buildings, being 1,300 feet long, and 525 feet wide; the cost was £139,200. Owing to the size of each exhibit the number of entries was not large; but the building contained many novelties of importance. Perhaps the most up-to-date exhibit was a model of the new 25-knot turbine steamer now under construction for the Cunard Steamship Company, Limited. The same company exhibited a most important historical series of models constructed to the same scale, commencing with the 440 horse-power 8½-knot *Britannia* of 1840, and finishing with the turbine steamship just referred to, of 75,000 horse-power.

The railways of the United States were well represented both as regards cars and engines. A complete train of Pullman cars, containing the most recent improvements, was a very popular attraction. So complete and substantial are these cars at the present time that the weight amounts to about 2 tons per passenger. The Baltimore and Ohio Railway Company showed a unique historical collection of locomotives from the earliest types down to the latest Mallet articulated compound locomotive with 4 cylinders and 12 driving wheels. A very striking object-lesson was a powerful locomotive of the American Locomotive Company, mounted upon a high turntable, 70 feet in diameter, and rotating by means of an electric motor. The weight of engine and tender was 145 tons. Another exhibit that attracted much notice was the high-speed engine of Messrs. Henschel and Son, of Cassel, designed to draw a train of 200 tons at a speed of 80 miles an hour. Its weight, including tender, was 136 tons, and in several particulars its construction differed from the usual practice. To diminish the air resistance the upper part of the engine is encased in steel plates and the front is wedge-shaped. It has run 85 miles per hour with three cars and developed 1,775 horse-power with a coal consumption of 2½ lb. per horse-power. A full-sized model of the Pennsylvania Railroad Company's tunnel under the Hudson River at New York which is now approaching completion showed some special features. The ground being treacherous, stability for the tunnel was secured by driving massive iron piles through the floor of the tube and uniting their heads by means of girders. The English engineer, Mr. C. M. Jacobs, M.I.C.E., has embodied some other features of interest in the construction. The same railway company carried out a careful series of tests on 20 locomotives in this building, 25 men being employed continuously. Numerous safety appliances for railways were exhibited; inventors evidently hope that American railway companies may some day feel ashamed of slaughtering 12,000 human beings

annually on their lines and adopt some of the precautions that have proved successful in other countries.

To the department of transportation belongs the *Aeronautical Section*, of which great things were expected. The management of the exhibition incurred considerable expenditure and devoted a large area to the appliances necessary for aeronautical competitions. Very large money prizes were offered, and although the conditions of the contests were somewhat severe, yet, as Mr. Willard A. Smith, the chief of this department, rightly says, the aim was to induce aeronauts to produce something superior to that which is already known, not merely to institute a competition between well-known appliances.

The authorities of the exhibition are to be congratulated upon the courageous effort which they have made to advance the one form of locomotion in which man lags behind some of the humblest of his fellow-creatures. Although no aeroplane entered the lists, yet the kite competitions, and gliding experiments afforded some valuable information, and there can be little doubt in the minds of those who have studied the subject carefully in the light of modern improvements that most of the elements necessary for mechanical flight already exist. It is remarkable that none of our philanthropic millionaires have contributed towards the solution of a problem which would confer such lasting benefits on mankind.

The next building, which we will consider, is that devoted to *Forestry, Fish, and Game*, which is one of the smaller structures, although 600 feet long and 300 feet broad. What impresses the visitor most is the enormous variety of timber—lumber, as it is called here—which has been brought together from all parts of the globe, but especially from the United States. The exhibition buildings themselves form the best object lesson of the use of yellow pine, of which they contain four hundred million feet. Numerous objects made from wood were shown, together with a very varied collection of forest products of all nations. Some of the groups of game and fur-bearing animals and of birds were very artistically mounted in their natural surroundings. In another part of the grounds the Department of Fisheries of the United States had a special building devoted to fish and fish products. Here fish hatcheries were shown in operation, and the various edible fishes of the United States displayed alive in capacious tanks.

We now come to the *Agricultural Building*, the largest of all, being 1,600 feet long and 500 feet. broad. The floor space is about 20 acres, and to inspect all the exhibits a walk of about nine miles would be necessary. The whole of our 1851 exhibition could be placed inside this building. The cost of construction was £106,000. It will be evident that the time at my disposal is quite insufficient to give even a superficial idea of the contents of this enormous building. A large working exhibit, of British origin, of confectioners' and bakers' machinery was very popular, but on the whole the building chiefly contained products from the United States. Nearly every State had an exhibit, and there was much rivalry in displaying the various products to the best advantage. The State experiment stations showed their results in concise and attractive form, and distributed instructive literature free of cost to all those interested. Some of the agricultural trophies were well designed, and would have had an excellent effect had they not been dwarfed by the gigantic building in which they were placed. The Canadian trophy showed that the Dominion is far advanced in the production of grain of various kinds, and its collection of honey was the best exhibited. This building undoubtedly contained the finest collection of agricultural produce ever brought together, and was well calculated to convey a favourable impression of the enormous agricultural resources of the United States. After wandering for miles through lanes of wheat, maize, tobacco, cotton, sugar-cane, &c., one could not fail to realise that agriculture is still the chief industry of the country. Labour-saving appliances were numerous, windmills and automobiles especially being adapted to a variety of purposes. An eight-share automobile plough by means of which two men can plough 40 acres daily would probably find few purchasers in Great Britain; but the first one sold went to Johannesburg. It was curious in travelling through the country to see some of these most recent implements at work on farms alongside the old-fashioned snake-fence, so wasteful of land and timber. Dairy products were well represented, one striking exhibit being a number of life-size groups modelled in butter and arranged in a refrigerator with plate-glass sides. The creameries in the United States have got over the difficulty of milk dilution by buying their milk according to its percentage of butter fat which is estimated in a very simple manner.

The Horticulture Building is of more moderate dimensions, covering only six acres.

In it the exhibit of Californian fruit and vegetables first claimed the attention of the visitor. Many of the fruits and vegetables were preserved in glass jars, not in alcohol but in an aqueous fluid that did not affect their colour. The dried fruits, such as raisins, prunes and figs, were specially well represented. The varieties of fresh fruit were not so numerous as in some of our own shows, but their quality was excellent, especially in the case of the apples. There were large quantities of grapes, many of them of the strongly flavoured Concord variety which would scarcely find a market in this country. The production of grapes in California appears to be greater than is required for wine, as the Grape-Growers' Association is offering considerable prizes for other uses for grape-juice. The growth of seedless oranges has become a large and thriving industry, and seedless apples and gooseberries are now being produced. In this building, if anywhere, one might expect to find the reason why our own fruit-growers are unable to compete with American apples grown several thousand miles away. Professor L. R. Taft, of the Agricultural College, Michigan, a high authority on horticulture, and the chief of this department, was kind enough to give me much interesting information on this subject. The careful grading of the fruit seems to be one of the chief elements of success. Only the finest fruit is put upon the market, inferior apples are used for cider or other purposes. As soon as possible after gathering the fruit is placed in a cooled store where its owner can keep it until the market conditions are favourable. Our own growers flood the market with their fruit at a time when the glut is greatest, and although the quality of their fruit may be even better than that of the imported article the price which they obtain is much lower. A little organisation should change this and a refrigerated store in each of our fruit-growing counties ought to be a highly remunerative undertaking. At St. Louis we had thirty carloads of last year's apples in the refrigerators and some of them were in such good condition that when placed on the show-bench with this year's crop it required an expert to distinguish between them. Another point in which our American competitors excel is in the division of labour. It is the farmer's business to grow the fruit and he does this with the fullest attention to those details which experience and scientific teaching have shown will lead to success. The ground is carefully tilled and manured between the trees and insecticides are used freely, if necessary. When the crop is ripe the farmer's work ends. He sells the fruit as it stands to the dealer who, with the help of his trained hands, gathers it carefully without bruising, grades it, packs the best fruit on the spot in suitable packages, and sends it either to a refrigerated store or in refrigerator cars to the coast for shipment to our markets.

During the summer a fine series of flowers was exhibited, both growing in the grounds and cut in the building. One of the outdoor exhibits was a floral map of the United States, occupying six acres. In each State plants were grown representative of the agriculture of the district.

I will merely mention the *Art Palace*, as I understand that Mr. Isidore Spielmann, Member of the Art Committee of the Royal Commission, will shortly read a paper on the subject before this Society. Those who are the fortunate possessors of Mr. Spielmann's artistic souvenir of the British Art Exhibits at the Paris Exhibition of 1900, will be glad to hear that the description of our excelleut art exhibit at St. Louis is in such able hands. Seventeen nations were represented in the 134 galleries of this building, not only by paintings, but also by statues. France and Germany, especially, had some good pictures. The whole exhibition and its grounds were sprinkled with American statuary, some of which was of striking originality.

Among the art exhibits must be included the Jubilee presents of Her Majesty, the late Queen Vietoria, which had been lent by His Majesty King Edward VII., and which were probably the most popular feature in the whole exhibition. They were exhibited on the first floor of the Administration Building, a substantial stone structure which will become the home of Washington University on the close of the exhibition. The collection has been visited by nearly a million persons, a very large proportion when one remembers that the building in which they were displayed is about a mile from the chief entrance to the exhibition.

In a wing of the same building was the *Hall of Anthropology*, under the management of Prof. W. J. McGee, the distinguished president of the American Anthropological Association. While the building itself contained numerous interesting American remains, especially a unique collection from the pre-historic mounds of Ohio, the chief attraction centred in the various groups of natives collected from

all parts of the globe. First in point of numbers and importance may be mentioned the natives of the Philippine Islands, of whom there were 1,300. A reservation of 47 acres of woodland was set apart for the villages of the Moros, the Bagobos, the Visayans, the copper-coloured head-hunting Igorotes, and the pigmy Negritos. Hairy inus, the primitive white race from the north of Japan, were well represented, also the Patagonian Indians and Esquimaux from Labrador and Alaska. Many tribes of North American Indians were there, and a group of the Osages, the former owners of the exhibition site, came from their reservation to visit the "World's Fair." In preparing the ground for the exhibition a number of prehistoric mounds were removed; some of them were 48 feet in diameter and about 3 feet high.

Perhaps the British policemen formed the most popular anthropological exhibit. A number of well-selected men of the Metropolitan force were in charge of the Jubilee presents and the British Pavilion. After many investigations the local reporters published as a fact that if you asked an English policeman a question you would always get a polite answer, and the consequence was that a large number of visitors tried the experiment with satisfactory results.

The British Royal Pavilion was a replica of the Orangery at Kensington, standing in an old English garden which attracted much attention. Inside the building each room was fitted up in a style representing a certain epoch, both as regards decoration and furniture. The construction of the building was much more durable than that of the other structures, Portland cement having been substituted for plaster of Paris. Among the other buildings of foreign States may be mentioned the French Pavilion, a replica of the Grand Trianon; the German Pavilion, a copy of Charlottenburg Castle, containing an interesting collection of furniture and presentation plate, and the Brazilian building. Most of the States of the Union had buildings, some of which were of considerable size and architectural merit. Altogether there were said to be more than 1,500 separate buildings on the grounds.

No account of the "World's Fair" would be complete without some reference to the Pike. This was a street, or rather village, about a mile long adjoining the main entrance to the exhibition. The buildings composing it were all places of amusement or entertainment. Some of them, such as the Tyrolean Alps, Hagenbeck's Menagerie and the Irish Village were well worth visiting, but from the majority one emerged with a feeling of disappointment. Among the out-door exhibits of a scientific character one of the most notable was Professor M. A. G. Himalaya's solar furnace. This consists of a large parabolic reflector composed of more than 6,000 pieces of silvered glass, the whole being fixed on a pivoted axis. In the focus of the mirror is a furnace in which Professor Himalaya hopes to obtain even higher temperatures than those which can be produced by means of the electric arc. He has been working on the subject for several years with remarkable perseverance, and we must wish him success in his efforts to extend the limits of human knowledge.

I feel sure that you will join me in thanking the Royal Commission for the St. Louis Exhibition for permission to use some of their photographs. I am especially grateful to Colonel Watson, the British Commissioner at St. Louis, for much valuable information and assistance, and Mr. E. J. Lloyd has kindly sent me some photographs of objects of special interest.

There were innumerable other things of interest at St. Louis to which time will not permit me to refer. I trust that the brief sketch I have given has been sufficient to show that the hope expressed by our president, His Royal Highness, The Prince of Wales:—"That the representation of this country in the various departments of the exhibition may be worthy of the British Empire," has been fulfilled.

DISCUSSION.

The CHAIRMAN, in opening the discussion, said that in November, 1903, he had the pleasure of listening to the address delivered before the Society by Mr. George F. Parker, on the subject of the St. Louis Exhibition, and in the course of the subsequent discussion he referred to the difficulties which the various Committees of the Royal Commission had experienced in organising representative exhibits, pointing out that in the case of the group with which he had been concerned, namely, that of chemical and pharmaceutical arts, success would probably not have been achieved if exceptional facilities had not been afforded by the Royal Commission. Even with that help, unremitting labour was needed for many months, and he was very glad to know the author considered it a question well worthy of careful consideration, whether some steps could not be taken to preserve something like continuity of effort, or at any rate, to create such a permanent organisation as would render it comparatively easy on a future

occasion to start from the point at which they had now arrived, and thus to have available the experience which had been gained. Obviously the first step in that direction was to procure a general recognition of the principle that international exhibitions, with sufficiently long intervals, were desirable. The prevailing tendency unquestionably was for manufacturers to regard them as evils, and with that sentiment he had considerable sympathy; but he was of opinion that they should be regarded as necessary evils, and if there was an agreement on the point it appeared to him to follow that they should participate in them. That being granted, the next step was to realise that if they took part their co-operation must be full and complete, for half-hearted, reluctant action might easily become worse than abstention. He submitted that it was in the second step that Great Britain had shown weakness in the past. When he spoke on the occasion to which he had referred he ventured to say that the sub-committee over which he presided had been stimulated to special effort by the determination to show that the comparatively unsatisfactory character of British chemical exhibits at recent exhibitions was due to British apathy and not to British industrial decadence. He admitted that ground had in the past been furnished for the contemptuous attitude of mind of foreign competitors in chemical industry towards this country, and he indicated that the exhibits at St. Louis would remove that reproach and demonstrate that Great Britain could still venture to put herself in comparison with other countries as possessing exceptional advantages in the conduct and development of the industry in question. The statements of the author, coupled with the long list of awards, had amply justified the view to which he gave expression, for England had shown the world that, even with such a formidable competitor as Germany, it could hold its own, and he was sure there were none present who were not satisfied that a full equivalent had been obtained for the labour and expense which it had involved. It was impossible to measure the direct commercial benefits accruing to the manufacturers who had so loyally and effectively collaborated with the Royal Commission in giving effect to the wishes of the Prince of Wales, but that those benefits must be large and far-reaching could not be doubted. As had been pointed out in the preface to the descriptive catalogue of chemical and pharmaceutical exhibits, the manufacturer had been enabled to judge whether he was gaining ground, or was being distanced by his competitors at home and abroad, and had thereby been placed in a position to make suitable provision for the future. If, therefore, manufacturers would admit that participating in international exhibitions should be recognised as forming part of the routine work incidental to their business, they had to consider how it could be simplified and rendered more effective. Strong exception had, in the past, been taken in this country to the practice of forming collective representative exhibits, which had long been successfully carried out by some other countries, but he ventured to think that the principle, which had been for the first time adopted by the Roy Commission in organising the exhibits at St. Lou and especially the chemical exhibits, namely, that o collectivity without sacrifice of individuality, had been shown to be free from objection. As was stated in the preface, the system of grouping adopted had been found to facilitate the study of the exhibits, and to add largely to their educational value. It must not be assumed that in preparing collective exhibits in that new form there was any less need for the exercise of independent thought on the part of the exhibitor, or less opportunity for the display of individuality; it had, in fact, been shown that the exhibitors in the chemical section, in responding to the appeal of the Royal Commission, had aimed with conspicuous success at furnishing an instructive series of illustrative specimens, as well as the ordinary selection of commercial products. To insure success in carrying out the principle of collectivity, it was essential that the organising arrangements should be in the hands of committees who were not merely conversant with the industries to be represented but also had full knowledge of the various firms engaged in those industries. It was evident that the hope of advancement of material interests rendered those firms most willing to participate which were least qualified to pose as representatives of the particular trade or branch of commerce in which they were engaged, and it would readily be understood that as the primary object must be the national one of demonstrating what any particular branch of British industry was doing, or could do, in comparison with what was accomplished by other countries, everything depended upon the judicious selection of exhibiting firms. If collective exhibits illustrative of British industries were to be a feature of future international exhibitions, it would appear to be desirable that there should be some permanent organisation, such as the author had suggested, to preserve and extend the knowledge and experience of procedure already gained. The appointment of a joint standing committee would be one way of accomplishing that end, and he submitted that some action in that direction might fittingly be initiated by the Society of Arts.

Mr. H. J. HELM said that as Mr. Reid's colleague he would like to emphasise the importance of the preparatory work that was done in London before they left England. He was quite sure that any success that Mr. Reid and himself might have attained at St. Louis was more than half won by the work that was done in committee rooms in London before they started for America. He wished particularly to mention the admirable catalogue and the splendid articles on the technology of the various industries that were represented. They not only admired the catalogue themselves, but took care that every member of the jury should have it in his posses-

sion in time to read and study it before he criticised the British exhibits. The exhibits were admirable, but there was no exhibits in the whole of the exhibition that were more admirably displayed, and more compactly arranged, than those belonging to the chemical and pharmaceutical section of the British exhibits, and a visitor in that section saw, with very few glances, more than he could have seen of the exhibits of almost every other country by wandering from one building to another. The American exhibits, although good separately, were scattered over so many buildings that they very largely lost their importance. He thought the exhibitors in this country who sent their goods to the exhibition were deeply indebted to the sub-committee of the Royal Commission, which made such admirable arrangements, and which, in his opinion, won half the battle. He also wished to confirm everything the Chairman had said as to the admirable fitness of his colleague for the position that he held on the jury at St. Louis. Mr. Reid had many qualifications which he had not. In the first place, he had not only a very large amount of tact, courtesy and discretion, but a wonderful knowledge of languages which enabled them to tide over many difficulties with the jury which would otherwise have seemed insuperable. He had never had a more admirable colleague to work with.

Mr. J. W. Lovibond wished, as one of the exhibitors, to expresss his deep sense of obligation to the members of the Royal Commission for the care which they gave to the interests of British industry; until he saw the photographs and heard the paper, he was totally unable to realise the extent of their labours and the obligations which rested upon them.

Sir Henry Wood (Secretary of the Society) thought that if exhibitions were to be held in the future, the success of any national section rested entirely upon the way in which the exhibits were organised into collective exhibits. That fact became perfectly evident to all who studied the working of exhibitions at the great French Exhibition of 1889. England was, proverbially, rather slow in learning lessons from other countries, but he thought they were to be congratulated that those who had to do with exhibitions in this country had at length learnt that lesson, which ought to have been learned in time for the exhibition at Chicago in 1893. The Royal Commission at that time had no funds with which to undertake the organisation of such exhibits, but some efforts were made to induce localities or classes of exhibitors to arrange themselves into collective exhibits. He was sorry that the efforts failed, and how they failed might be instanced by one example. There was one particular class of manufacture, in which this country made a very excellent show at Chicago, and there were three or four large exhibitors who were ready to exhibit, and did exhibit. He did his best to induce those exhibitors not to join together in one exhibit, but to allow their exhibits to be combined into some sort of harmonious whole. Certain of the exhibitors agreed, but one of the most important said at once that if anything of the sort was attempted he would have nothing to do with the exhibition. The result was that there were separate and independent exhibits, all of a very high class, but the section as a whole lost a great deal from the want of harmony which might have been brought into it. As one who had a good deal to do with an American exhibition more than ten years ago, he should not like to refer to exhibitions in America without bearing his testimony to the kindliness and fraternal good feeling with which English representatives in America had always been received. It was so in the first great American exhibition, the centenary exhibition at Philadephia, and it was equally so, as he knew best of all men, in the exhibition at Chicago, and he had not had the slightest doubt it was so at St. Louis. The British section at Chicago, the only exhibition in America with which he was personally concerned, was a foreign section like the rest, but the representatives of Great Britain were not looked upon as the representatives of a foreign country; they were regarded, and he believed they regarded themselves, as individual members of the staff of the exhibition, and he always considered it a very great honour, and a very great piece of good fortune, to be constantly consulted, and to place such experience as he possessed at the disposal of the managers of that great exhibition. He had no doubt that the same feeling existed at St. Louis, and if another exhibition was held he had not the slightest doubt but that the British staff and the British Commission would be regarded as portions of the staff of the exhibition, and not as aliens or outsiders. With regard to the beautiful buildings of which pictures had been shown, nobody who had not seen the two last great exhibitions of America could compare the two, but he could not conceive any exhibition, past or future, which presented a more splendid architectural appearance than the exhibition of Chicago, as viewed from the great inland sea, on the shores of which it was placed. He, indeed, doubted whether there were any buildings in the world at that time which, regarded from a sufficient distance, a mile or so out on Lake Michigan, presented a more splendid architectural effect than those apparently magnificent palaces which were erected at Chicago in 1893. As one who had had a great deal of experience of exhibitions in the past, he wished to congratulate the author of the paper first, upon the excellent way in which he had presented a very complicated subject, and secondly upon the manner in which he had conducted one of the most difficult duties connected with exhibitions, namely, that of successfully carrying out the work of the jury.

On the motion of the Chairman, a hearty vote of thanks was accorded to Mr. Reid for his able paper.

Mr. REID, in reply, said that his colleague and friend, Mr. Helm, had given him far more credit than he deserved; he never wished to have a more laborious and painstaking colleague than Mr. Helm on the work of any jury. He wished to endorse every word Sir Henry Wood had said with regard to the way they were treated in America; they were treated not only as cousins but as brothers. Everywhere they went they were received with open arms, and the difficulty was that they had to refuse so much hospitality that he feared some of the hosts were disappointed.

MILK IMPURITIES

One of the most difficult and important problems of the day is how to secure pure milk in sufficient quantities to meet the needs of the rapidly increasing population. So far as quantity is concerned, townsmen have no cause of complaint. They can get as much milk as they want at reasonable cost, but in many country districts the villagers find it difficult, if not impossible, to obtain a sufficient supply. The milk is sent away to meet the town demand, and they have to be content with the preserved product. But it is the quality of the milk that gives the gravest cause for anxiety. No doubt too much can be made of the impurities to be found in much of the milk supplied to London and the great centres of population. The dangers to life lurking in the milk pail and the milk shop are many and serious, but it may go some way towards reassuring the timid, alarmed by gruesome analysis, if they are reminded that, although milk swarms with bacteria, most of them are harmless. Dr. Vincent, who is Physician to the Infants' Hospital at Hampstead, and has given much attention to the subject, says that no matter what precautions are taken, you cannot get away from bacteria. It is not those bacteria which cause injury; lactic acid bacteria helps the infant, without them it is probable that no infant would live. The danger lies in the development of bacteria, and this can only be prevented by precautions that are very general on the Continent, more especially in Denmark and Sweden, but are not as yet commonly adopted in this country. "It is incredible," said Mr. Justice Grantham in his charge to the jury in a recent case, "that cows are allowed to be milked in such surroundings, and their milk sent to London."

Before considering the best means of removing the abuses complained of, it may be useful to cite some of the evidence as to the conditions under which milk is obtained and distributed to the public. The origin of the trouble is in the indifference of the farmer to cleanliness. In her evidence before the Inter-Departmental Committee, Mrs. Watt Smyth makes some very strong observations on this point, and although they are much too sweeping, it will be allowed by those acquainted with farms that the following description applies to many of them:—

"The cows are in a most filthy condition, standing in the manure, and the cowsheds, the stalls, are covered with manure, and outside the yards are heaped up with it. There is no proper ventilation, the milkers are filthy, their hands and clothes are dirty, and their vessels very often are dirty."

And Dr. Newman, Medical Officer of Health for Finsbury, who has conducted an inquiry into the milk supply of the borough, arrives at much the same conclusion:—

"There is evidence to prove that, as a general rule, the country cowsheds from which the milk is derived are ill-lit, over-crowded, badly ventilated, and badly drained. There is little or no guarantee that the milk is derived from healthy cows."

Nor are the risks of contamination over when the milk has left the farm. Much of the milk consumed in the poorer quarters of London is three or four days old, and it has passed through the hands of several dealers by each of whom a dose of some preventive has been added in order to prevent the actual onset of decomposition. "The mischief," says Dr. Priestley, Medical Officer of Health for Lambeth, "is caused by the many hands through which it passes. If there were some system of collecting milk in the country and sending it straight to milk depôts, it would be better." The evil is not at an end even when the milk reaches the home of the consumer. As the report of the Committee points out, "a pure supply may be rendered injurious by dirt in the house, the proximity of contaminating articles, the general ignorance in fact that prevails as to how milk should be stored, and the conditions under which it is fit for use."

The first thing to be done is, as many urge, to reform farm practice, to compel the farmer to do certain things to insure the purity of his milk. To compel, because, without compulsion, the majority of farmers will not move in the matter. But assuming this, how is the necessary pressure to be brought to bear upon them? Before the local authority can move the medical officer must report, and, oftener than not, when his report is received it is pigeon-holed. Speaking generally, the local authority is not in much sympathy with reform, and will do little in its direction without the pressure of public opinion, and that seldom exists. True, the medical officer may write to the Local Government Board, and if the local authority persistently ignores his representations it is his duty to do so. But his position is a very difficult one. Except in London he can be dismissed by the local authority without cause shown, and he would be dismissed if he took up a hostile attitude towards his employers and appealed to the Local Government Board to put pressure upon them to do that which they have no wish to do. It would seem desirable to make medical officers independent of the local authority so that they may do their duty without risking the loss of the means of livelihood.

But as the law stands the Local Government Board itself can do little against a local authority bent upon doing nothing. The Local Government Board may make orders for the registration of cowkeepers, dairymen, &c.; for the inspection of cattle in dairies, and for prescribing and regulating the lighting and ventilation, cleansing, drainage and water supply of dairies and cowsheds; for securing the cleanliness of milk stores and vessels. It has issued model bye-laws for urban and rural districts respectively. But the legislation under which it acts is permissive not mandatory. The Board may advise, it cannot compel. The report of the Inter-Departmental Committee on Physical Deterioration recommends that in the event of the local authority not making orders, the Local Government Board shall make the orders themselves, or if it is deemed preferable to bring indirect pressure to bear, the power now possessed by a local authority under the Infectious Diseases (Prevention) Act, 1890, for prohibiting the supply of milk from an infected dairy might, in the opinion of the Committee, be extended, so as to cover exclusion of supply from areas where provisions of the Contagious Diseases (Animals) Act are not in operation. Under either alternative the Committee consider that the County Council should be empowered to act in default of the local authority, and it should be the duty of the Local Government Board to intervene in the ultimate resort.

The crux of the question would seem to lie in the power to enforce the regulations necessary to preserve milk against contamination, and how to provide *ab initio* for the purity of milk. In expert opinion, the first step to be taken with milk on its leaving the cow is prompt refrigeration to a temperature of 40 degrees Fahrenheit. This was advocated by Dr. Cantley in the paper he read at the Royal United Service Institute last week. The enforcement of this procedure would stand in the way of the small cowkeeper sending his milk to the agents of the great collectors who serve the urban market, but having regard to the scarcity of milk in rural districts it might be a good thing if these small men had to look to their neighbours to purchase their milk. Dr. Cantley contends that the only plan for dealing with the matter thoroughly is to municipalise the milk supply. "Its management should pass as soon as possible directly into the hands of the municipal authorities, rather than through the intervention of milk companies which would eventually have to be bought up in the same way as the water companies." That is a very big suggestion, and although at Battersea, and some other places, steps have been taken in this direction, it may be thought better, for the present anyway, to work on less ambitious lines. It is to be regretted that our farmers have not seen their way as yet to co operation. The wonderful development of dairies in Denmark is largely due to the co-operative system. This system was adopted to meet the want of organisation felt by the farmers and has proved eminently successful. Denmark led the way, Sweden followed, then Germany, and in all these countries the resulting success has beeen great. Sir Horace Plunkett, and the Department of Agriculture, are moving in the same direction in Ireland. Under the co-operative system, as worked in the Continental centres named, there is constant inspection of dairies by officials of the societies. The utmost care is taken to ensure the proper feeding of cows, and to guard against contamination. The management of their cows and milk-sheds by many English farmers leaves little or nothing to be desired, but the majority are less alive to what can and ought to be done in the way of protection against contamination. They would find it to their advantage to be more abreast of the times; and now that the public are beginning to realise what a pure milk supply means to the health of the country, it may be expected that Parliament will be asked to give the Local Government Board those fuller powers which will enable it in the last resort to apply effective pressure in order to bring about changes necessary to the public health.

ELECTRO-THERMIC PROCESSES FOR IRON AND STEEL MANUFACTURE.

The receipt, in London of the publication by the Department of the Interior of the Dominion of Canada, of the Report of the Commission sent to Europe "to investigate the different electro-thermic processes for the smelting of iron ore and the making of steel," almost exactly synchronized with Sir William Abney's address to the Society of Arts, on the relations between the State and scientific research. This report is significant in many respects. It is, perhaps, an almost unique example of the Government of a self-governing British colony appointing a Commission to investigate manufacturing processes, and to report on their probable utility as a factor in the development of a promising metal-working industry within the colony. It is also noteworthy, as an instance of a Government Department investigating a scientific and commercial problem through a committee of experts directly selected, rather than through a recognised scientific institution.

In its entirety, the report covers, with its appendixes, over 220 large crown 8vo. pages, is illustrated by 24 plates, and 29 diagrams. The story of the genesis of the Commission may be briefly told. At the end of 1903, the Hon. Clifford Sifton, Minister of the Interior, instructed Dr. Eugene Haanel to proceed to Europe to investigate this problem, taking with him an electrical engineer, a draughtsman, and a private secretary. On arrival in England, a competent metallurgist was to be engaged. Mr. F. W. Harbord, of Cooper's-hill, the consulting metallurgist and analytical chemist to the Indian Government, filled this post.

The Commission immediately proceeded to Sweden,

to investigate the Kjellin process at Gysinge. Here high-class steel is made by melting charcoal pig and scrap iron in electric furnaces of the induction type, *i.e.*, in furnaces without electrodes, in which the metal to be treated acts as the secondary coil of an alternating current transformer. The quality of the steel produced by this process depends entirely upon the purity of the compound materials employed. The process therefore corresponds to the crucible steel process, save that the melted material is at no time during the operation exposed to the furnace gases, which, if absorbed, deleteriously affect the quality of the product. Mr. Harbord reports that the estimated cost of steel produced at Gysinge is 34 dols. per ton of 2,000 lbs.

The Commission next proceeded to Kobfors—also in Sweden—where the Héroult process of making steel had been in operation. At the time of the visit, owing to the large stock of electric steel, the works were engaged in producing ferrosilicon. It was therefore at La Praz, in France, that the Héroult furnaces were examined. Steel is there made from scrap, melted down, and carbonized by carburite. The electrodes consist of square prisms made from retort coke, costing ten centimetres per kilogramme when manufactured. A demonstration was given at La Praz of the production of pig iron.

The most important experiments witnessed by the Commission were those made by Keller, Leleux and Company at their works at Livet. Some 90 tons of iron were used for the various experiments made to demonstrate the commercial feasibility of making pig iron and steel direct from the one by the electric process. The furnace is of the resistance type, and consists of two iron casings of square cross section lined with a refractory material and communicating with each other at their lower ends by means of a lateral canal. In starting the furnace the charge is introduced between the carbon blocks at the base of each shaft, and the electrodes which are then in their lowest position. The current passes from one electrode through the material to be reduced to the carbon block, and thence passes outside of the furnace by means of a copper conductor to the other carbon block through the charge in the second shaft to the other other electrode. The resistance which the charge offers to the passage of the current heats the charge, and the reduced metal flowing along the canal then conducts the current internally from one electrode to the other electrode. The electrodes are formed by an assemblage of four electrodes of square cross section, forming a single mass 850 mm. by 850 mm. by 1·4 meters long. The inventor stated that the electrodes employed for a furnace having an output of 10 tons in 24 hours will last 20 days.

Three sets of experiments were made before the Commission. In the first, iron ore was electrically reduced, yielding grey, white, or mottled pig iron as desired. In the second set, the iron ore was electrically reduced with a definite amount of carbon in the charge, with a view to ascertaining the amount of electric energy absorbed in the production of one ton of pig iron. In the third set, ordinary steel of good quality was produced from the pig iron manufactured in the preceding experiments.

The Stassano furnace at Turin was visited, but was not in operation at the time of the visit of the Commission. The Harmet and Gustave Gin processes, both described in the appendixes to the report, were not in operation at any plants at that time.

In a very concise summary, which follows, the detailed descriptions of the various tests (both from the commercial and from the metallurgical standpoints), Mr. Harbord expressed his general conclusions. These may be summed up in the following abstract:—

Steel, equal in all respects to the best Sheffield crucible steel, can be produced by the Kjellin or Héroult, or Keller processes, at a cost considerably less than the cost of producing high-class crucible steel. However, in the present state of the industry, structural steel cannot be produced in the electric furnaces, at a price which will compete with Siemens or Bessemer steel. Therefore, so far as steel is concerned, the electric furnace can only be used commercially for the production of very high class steel for special purposes.

The reactions in the electric furnace, in regard to the reduction and combination of iron with silicon, sulphur, phosphorus, and manganese are similar to those taking place in the blast furnace. By altering the burden and regulating the temperature (by varying the electric current), any desired grade of iron, grey or white, can be obtained, the change from one grade to another being effected more rapidly than with the blast furnace, which would contain a much heavier charge.

Grey pig iron, suitable in all respects, for acid steel manufacture, either by the Bessemer or Siemen's process, or for foundry processes, can be produced. When pig iron, low in silicon and sulphur, is needed for basic processes, it can be produced, provided that the ore mixture contains oxide of manganese, and that a basic slag is maintained by suitable additions of lime. Mr. Harbord even goes so far as to express his belief that pig iron for basic processes can be produced even in the absence of manganese oxide in the iron mixture, provided that a fluid and basic slag be maintained.

On the commercial side, Mr. Harbord's conclusions are of special value. "Pig iron can be produced on a commercial scale, at a price to compete with the blast furnace, only when electric energy is very cheap, and fuel very dear. On the basis taken in this report, with electric energy at ten dollars per electrical-horse-power-year, and coke at seven dollars per ton, the cost of production is approximately the same as the cost of producing pig iron in a modern blast furnace. Under ordinary conditions, where blast furnaces are an established industry, electric smelting cannot compete; but in special cases where

ample water power is available, and blast furnace coke is not readily obtained, electric smelting may be commercially successful. It is impossible to define the exact conditions under which electric smelting can be successfully carried on. Each case must be considered independently after a most searching investigation into local conditions, and it is only after these are fully known that a definite opinion as to the commercial possibilities of any project can be given."

Dr. Haanel controverts none of these points in his own summary. He does, however, emphasise the fact that the experiments at Livet were carried out in furnaces not specially designed for the production of pig iron from iron ore. An inproved furnace would, in Dr. Haanel's opinion, give even better results. So far as cheap power is concerned, Dr. Haanal states that he is credibly informed at the Chats Falls, near Ottawa, the water power can be converted into electrical energy at four-and-a-half-dollars per electrical horse-power per annum. If this is really the case, the report of this Commission will mark the beginning of a keen struggle for the iron and steel market of North America, between Canada and the United States.

The Canadian Government in appointing this Commission has acted for the benefit of the Empire generally. British over-sea colonies and possessions cannot yet boast great iron industries. However, where ore is plentiful, and water power sufficiently cheap—as it may become, in course of time, in Southern India—fairly large local industries may, and probably will, spring up.

AGRICULTURAL EDUCATION IN CANADA.

It is reported from Ottawa that the millionaire tobacconist, Sir William Macdonald, is about to establish at St. Anne's, some twenty miles from Montreal, an institution, to be known as the Macdonald Foundation for Rural Education. For this purpose 700 acres of land has been bought, and a million dollars are to be spent in the completion of the scheme. Sir William Macdonald—who was knighted in 1898—has already given between two and three million dollars for educational purposes to the McGill University, and built and maintains the Macdonald Institute at Guelph for women desirous of taking a course analogous to that provided at the Ontario Agricultural College for Men. The new institution is expected to serve for the Province of Quebec a purpose analogous to that served by the college and farm at Guelph for the Province of Ontario. Mr. Robinson resigns his position as Dominion Commissioner of Agriculture to become principal of the new foundation. For some time past he has been identified with the establishment of schools for instruction in manual training, the encouragement of nature study, and consolidated rural schools, Sir William Macdonald providing the funds.

Sir William Macdonald's intention at St. Anne's is to found an institution where scientific instruction in all branches of agriculture can be given, and original research conducted. The experimental station will, of course, be available for varied experiments in the growing of crops. Only last month the new consolidated rural school at Guelph, which owes its existence to the munificence of Sir William Macdonald, was opened for school purposes. Professor Hodgson, of McMaster University, has been appointed Principal, and the experiment to be carried on by the school will be watched with much interest. There will be a consolidation of four school sections under one roof, and a staff of teachers doing the work that was formerly done by one teacher in each of the rural schools. It is hoped that this system, when understood, will be adopted by the various school sections throughout the province. By amalgamating, several school sections can erect a suitable building, have graded classes, and give to the rural scholars a much more efficient education than would be possible under the present method of one school to a section. The subjects taught go beyond the ordinary country curriculum. The main idea is to adapt education to rural needs, and endeavour to teach the children so that they will be in sympathy with country life, and not be so anxious to leave the farm. In amalgamating several school sections the difficulty of getting the scholars to school arises, but this is obviated by bringing the children in large vans. The school has six of these vans, and they call for the children within a radius of 5½ miles. The van calls at every farmhouse where there are children. Under this system of bringing children to the school the trouble, so marked in country schools in sparsely populated countries like Canada, of irregularity of attendance, will, it is hoped, be overcome. There is no age limit, but the school is confined to rural children. While similar schools exist in several American States, and in New Brunswick and Nova Scotia, the Macdonald school goes a step further in instruction, as it includes gardening, each pupil having a little plot of ground to be cultivated by himself.

ADMIRALTY CHARTS.

The following is the official list of charts issued by the Hydrographic Department, Admiralty, in September and October last:—

New Charts.—Diagram to facilitate the obtaining a ship's position by Sumner's method. 3239 to 3250—Monthly wind charts for the South Atlantic ocean; twelve charts bound together in an atlas. 3427—France, north coast:—Rade de Brest. 3383—Nova Scotia:—The gut of Canso. 3450—West Indies; Cuba, South coast:—Ensenada de Mora. 3454—Central America:—Plans of anchorages on the north coast of Panama. 3447—British Columbia; Vancouver's island, east coast:—Moresby passage with

its approaches. 3448—North America, west coast; Queen Charlotte sound:—Blunden harbour. 3430—North America; Vancouver's island:—Galetas and new channels. 3443—North America; Vancouver's island:—Nawhitti bar; Bull harbour. 3452—Persian Gulf entrance:—Khor Kawi anchorage. 3456—Bay of Bengal, east coast:—Cox's Bazar. 3453—Malacca strait:—Klang strait and approaches. 3368—Philippine islands; south part of Luzon island:—Batan I. to San Bernardino I., and Himagaan bay to Inamok. 3459—China, south-east coast; Hong hai bay:—Sam chau inlet. 139—Japan:—Ikitsuki jima to Taka shima, including the northern approaches to Hirado kaidyo. 3438—Japan:—O shima to Furubira wan. 3409—Japan:—Ishinomaki wan (Sendai bay) and Sakata ko to Tsugaru kaikyo (strait). 3439—Solomon islands, Ysabel:—Austria sound (plan, Allardyce harbour). 3455—Pacific ocean; Loyalty islands, Uvea atoll and Beautemps-Beaupré island. 1751—Rio de la Plata; Saucé point to Martin Garcla island (plan added, Saucé harbour). 1881—Indian ocean; Cargados Caragos islands (plan added, Agalega islands). 3031—Bays and anchorages on the east coast of Borneo (new plan, Buja and Manimbora anchorages). 1384—Pacific ocean, Loyalty islands; anchorages in (plans added, Dokin bay, Gaatcha bay, Ro bay, Poane bay, Aui bay).

Charts that have received additions or corrections too large to be conveniently inserted by hand, and in most cases other than those referred to in the Admiralty Notices to Mariners:—

Nos. 1188—The World; coal and telegraph chart. 2212—England, south coast; Teignmouth. 1776—Færoe islands; Trangjisvaag. 3159—Norway; Torbiornskier to Jœlöen. 3160—Norway; Torbiornskier to Ranö. 2300—Baltic; Gulf of Bothnia; sheet V., Stiernö point to Fiädeiág, &c. 2302—Baltic sea; sheet VII., Tome point round the head of the gulf to Tauvö. 3345—France, west coast; Chenal du Four. 274—North Polar chart; Atlantic side. 278 - North Polar chart; Pacific side. 2740 - Iceland and the Færoe islands. 2976—Iceland; Snefells Jökel to North cape. 2977—Iceland; North cape to Sigle fiord. 275—America, north coast; Smith sound, Kennedy and Robeson channels. 2564 - United States America, east coast; Delaware river; sheet II. 528—South America; sheet IV., Maranham to Pernambuco. 1911—United States, west coast; Approach to Juan de Fuca strait. 2908—Africa, south coast; Port Natal entrance. 2757—Banka strait to Singapore. 941*a*—Eastern archipelago, western portion. 941*b*—Eastern archipelago, western portion. 2637—Celebes; Strait of Makassar, south part. 1466—China, east coast; Hongkong; Fotaumun pass. 2409—West coast of Formosa and Pescadores channel. 913—Korea, west coast:—Mackau group to Clifford islands. 104—Korean archipelago, southern portion. 3365—Korea, south-west coast:—Port Hamilton to Mackau group. 980—Caroline islands.

These charts are issued by Mr. J. D. Potter, 145, Minories.

CORRESPONDENCE.

THE BRITISH CANALS PROBLEM.

In Mr. Lee's interesting paper on "The British Canals Problem," reported in the *Journal* of the 2nd instant, he seems to tacitly assume that a canal becomes derelict solely through neglect, deliberate or otherwise, and that no account need be taken of the effect of the speedier and more convenient competitive form of transit offered by the railway on the slow and cumbersome means afforded by the canals. There is no doubt that many of Mr. Lee's contentions are perfectly just, but it appears to me that a great deal too much has been imputed to "deliberate neglect" in describing the present condition of English waterways. I submit that in most cases a canal becomes derelict simply because it has ceased to be of use, just as the stage coach, for a similar reason, disappeared on the introduction of railways. It is impossible, indeed, that the canals can ever regain the importance that belonged to them when they constituted the only means for the inland transport of heavy goods. To advance extravagant claims in their favour is merely to defeat the object which Mr. Lee has in view.

In the paper, French waterways were referred to. I should like to mention a few important facts which Mr. Lee omitted. In the first place, the French waterways are quite unlike our own—they are mostly inter-dependent. In the second place, their chief use is not for through traffic, but is almost entirely local, or between particular points for certain special articles. It has also to be borne in mind that over 90 per cent. of French canal traffic is on first-class navigation, and the enormous length of secondary waterways, constituting three-fourths of the whole system, is wholly out of proportion to the necessities of transit. Another important fact is that the English canals carry half as much again in tonnage as the French, and yet, as Mr. Lee pointed out, France has spent many millions on the improvement of her navigable and artificial waterways. Has the increase of traffic been in proportion to the capital expenditure?

In these days of rapid transit the desperate slowness of canal transport constitutes its main disadvantage, and this is experienced in France just as much as in this country. To send goods by canal from Rouen or Havre to any point on the central canal system occupies any time from three to six weeks. Delay means expense, and until canal transport makes some approximation in the matter of speed, I will not say to the railway, but even to the road, traffic will naturally be diverted more and more into other channels.

After making full allowance for canals which have become derelict because they are practically useless, and also taking into account the disadvantage just mentioned, there is no doubt that the utility of our waterways could be largely increased, but I venture to assert

that in view of the alarming growth of municipal expenditure, it would be a disastrous policy to give still further powers to the local authorities to add to their already heavy burden of debt. What data can Mr. Lee supply to show even a probability of a sufficient increase of canal traffic to justify such a course? In the present state of national finance, however, something more than a probability is necessary before incurring expenditure when the return may not even be sufficient to pay the interest.

When reform is needed in certain directions the first suggestion in most cases is to give the local authorities power to spend more money. The local authorities have already spent too much. In view of the undoubted limitations of canal transport it seems to me quite unnecessary to plunge into a course of expenditure when other means can be adopted. Granting that the railway companies place obstacles in the way of the full and legitimate use of the canals, the remedy is obviously to compel the companies to remove those obstacles and reduce their rates. If the private owners have a fair field for their enterprise they will not hesitate to incur expenditure on the improvement of their property, but if, from any natural circumstance, a canal cannot compete with the railway, or attract to itself a certain class of traffic, it will become derelict, and no artificial means of resuscitation will save it. At all events I submit that the remedy for whatever neglect exists is not to be found in giving *carte blanche* to the local authorities to add still further to their burdens and those of the community in general.

W. D. McConnell.

64, Burma-road, Clissold-park, N.
Dec. 6th, 1904.

GENERAL NOTES.

Society of Musicians.—The Incorporated Society of Musicians will hold its Twentieth Annual Conference at Manchester from January 2nd to 7th, 1905. Addresses will be delivered by Sir Frederick Bridge, on "A Weak Point in our Musical Education"; by Mr. W. A. C. Cruickshank, Mus.B.Oxon, on "The Progress of Music during the Nineteenth Century"; by Mr. James Dawber, Mus.B. Cantab, on "The Advisability of still further Safeguarding the Entrance to the Musical Profession"; by Mr. T. Henderson, Mus.B.Dunelm., on "Some Blots upon English Music"; and by Mr. S. Midgley, on "Municipalities and Music."

Automobiles for the Ceylon Government.—Up to mid-day on February 1st, the Government of Ceylon are open to receive tenders for the conveyance of mails and passengers between certain points in the island. There are five distinct sections, (1) between Bandarawela and Badulla, a distance of 18 miles, twice daily in each direction; (2) from Badulla to Bathcaloa, a distance of 105 miles, once daily each way; (3) from Matale to Trincomalee, a distance of 97 miles, once daily each way; (4) from Colombo to Chilaw, 50 miles, twice daily each way; and (5) from Chilaw on to Puttalam, a further 32 miles, once daily each way. The proposed service is required to commence on 1st July, 1905, the contract being for ten years.

Armorial Bearings.—Armorial bearings for Manitoba have been approved at the Heralds' College, and the Warrant authorising their use is about to be signed by the King. Similar action in regard to armorial bearings for British Columbia and Prince Edward Island will shortly be taken. These three provinces adopted armorial bearings without authority, hence they could not be embodied in the Coat of Arms of the Dominion. As soon as entry is made in the Heralds' College, and a Royal Warrant issued, the Arms of Manitoba, British Columbia, and Prince Edward Island can appear in the Dominion Shield. The four original provinces were granted armorial bearings in 1868. Mr. Joseph Pope, C.M.G., Under Secretary of State of Canada, has been working for several years to induce the three provinces to apply for approval of their heraldic devices.

Historic Ground.—There is fear of another fall of rock at Quebec, and Lieutenant Amio, of the Geological Survey, has been instructed to make a thorough examination of the cliff with a view to the adoption of such measures as will prevent a recurrence of the slide of 1889. There is a curved strata on the face of Cape Diamond which follows an upward turn, and at the foot of the King's Bastion dips towards the river. Since 1889 several crevices have developed at the King's Bastion which extend in a direction parallel with the foot of the citadel. There are other crevices underneath the west corner of Dufferin-terrace. The suggestion has been made that if the face of the cliff is cemented over it will prevent water from percolating through the fissures and further movements taking place.

American Wheat Exports.—Referring to the article on the British Wheat Supply that appeared in the last issue of the *Journal*, reports prepared by the Department of Commerce and Labour (U.S.), and just issued, show that the total exports of wheat during the nine months ended September 30 last were less than 10,000,000 bushels, as against 55,000,000 bushels in the corresponding months of 1903, 96,000,000 bushels in the similar period of 1902, and 139,000,000 bushels in the nine months to September, 1901. Even flour exports are beginning to show the effect of the great shortage in the wheat supply available for exportation, and for the nine months ended September they amounted to only 9,000,000 barrels as against 13,500,000 barrels in 1903.

Starlings in New South Wales.—The Government Entomologist of New South Wales, reporting to the Ministry of Agriculture, refers to the rapid increase in the number of starlings, and the injury they do. First imported from the Mother

Country not so very many years ago; starlings swarm in Victoria, and are gradually spreading northwards. Flocks of them have recently appeared in Sydney orchards and gardens. They are the greatest enemy of the fruit-growers, who have to cover their trees with nets (while the fruit is yet green) to keep the birds off. They are also claiming the attention of squatters who say they perch on the back of sheep and pluck out tufts of wool (presumably for nest lining), thus damaging the best part of the fleece.

HISTORIC HOUSES IN LONDON.—In May of last year the London County Council sanctioned the erection of a tablet at No. 122, Great Portland-street, in memory of James Boswell, the biographer of Samuel Johnson. The house in question, however, though occupying the site of the premises in which Boswell lived and died, is a comparatively new building; and before taking any action under the authority of the Council the Local Government Records Committee took into consideration the question whether it was desirable to continue the practice adopted in several instances by the Society of Arts of indicating such houses. As a result it was felt that, while there were in London so many cases in which the Council had the opportunity of erecting a tablet on houses which had actually been the residences of distinguished individuals, it was not desirable at present to take action as regards premises whose only claim to distinction was that they stood on the site of houses formerly occupied by the persons whom it was desired to commemorate. Steps were accordingly taken to ascertain whether there was in existence any house actually occupied by Boswell; and it has been discovered that he resided for some time at 56, Great Queen street. The committee now recommend that a memorial tablet should be affixed in Great Queen-street, and that the resolution with regard to Great Portland-street should be rescinded. In connection with this work of indicating houses of historic interest, the committee have had under consideration the question of the erection of a memorial tablet in memory of Sir Francis Chantrey. The only residence of Sir Francis Chantrey suitable for commemoration was 102, Buckingham Palace-road; but as that house has been recently demolished, the committee report that there is no residence of Sir Francis Chantrey's in London to which they can recommend that a memorial tablet should be affixed.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock:—

DECEMBER 14.—"The Patent Laws." By CHAS. D. ABEL. ALEXANDER SIEMENS, Vice-President of the Society, will preside.

APPLIED ART SECTION.

Tuesdays, at 4.30 or 8 o'clock:—

DECEMBER 20 (8 p.m.).—"Street Architecture." By THOMAS GRAHAM JACKSON, R.A. DR. G. B. LONGSTAFF, will preside.

Papers for Meetings after Christmas:—

"The Navigation of the Nile." By SIR WILLIAM H. PREECE, K.C.B., F.R.S.

"The Protection of Buildings from Lightning." By KILLINGWORTH HEDGES, M.Inst.C.E.

"The Present Aspect of the Fiscal Question." By SIR CHARLES MALCOLM KENNEDY, K.C.M.G., C.B.

"British Woodlands." By THE RIGHT HON. SIR HERBERT MAXWELL, Bart., M.P.

"The Supply of Electricity." By JAMES NELSON SHOOLBRED, B.A., M.Inst.C.E.

"Time Development in Photography, and Modern Mechanical Methods of carrying it out." By R. CHILD BAYLEY.

"London Electric Railways." By the HON. ROBERT P. PORTER.

"Lake Baikal and its Connection with the Great Siberian Railway." By ARTHUR GULSTAN.

"Some Misconceptions of Musical Pitch." By JOHN E. BORLAND. (*a*) *Visual*—due to conventional but inaccurate notation; (*b*) *Aural*—volume of tone mistaken for depth, brightness for height. Illustrated by voices, instruments and diagrams.

"Wireless Telegraphy and War Correspondence." By CAPTAIN LIONEL JAMES.

"The British Art Section of the St. Louis Exhibition." By ISIDORE SPIELMANN.

"Popular Jewelry." By MONSIEUR LALIQUE (Paris). (*Applied Art Section.*)

"The Cape to Cairo Railway." By SIR CHARLES H. T. METCALFE, Bart., M.Inst.C.E. (*Colonial Section.*)

CANTOR LECTURES.

Monday evenings, at 8 o'clock:—

DAVID JAMES BLAIKLEY, "Musical Wind Instruments." Four Lectures (with musical illustrations).

LECTURE III.—DECEMBER 12.—*Reed Instruments.* —Single and double reeds—Conical and cylindrical tubes—Bagpipes—Shawms, oboes, and bassoons—Clarionets—Saxophones.

Programme of Musical Illustrations.—Oboe Solo, Concertino, *Guillhaut*, Mr. J. L. Fontayne.—Clarinet Solo, Concertino, *Weber*, Mr. Charles Draper.—Bassoon Solo, Adagio from Concerto, *Mozart*, Mr. E. F. James.—Trio, Oboe, Clarinet and Bassoon, *Huguenin.*—At the Pianoforte, Mr. R. H. Walthew.

JUVENILE LECTURES.

Wednesday afternoons, January 4 and 11, 1905, at Five o'clock, CARMICHAEL THOMAS, "The Production of an Illustrated Newspaper." (Two lectures.)

LECTURE I.—JANUARY 4.—A short history of the early days of illustrated newspapers—Preparations for illustrating events—How sketches are made—

Special war artists—Photography on the battlefield—The amateur photographer—Drawing from sketches Siege sketches by balloon post—Mafeking sketches by Colonel Baden-Powell—Production of process plates.

LECTURE II.—JANUARY 11. — Compositors at work—Preparation of stereos—Manufacture of paper—The printing office—Folding and stitching machines—Colour printing—Importance of good titles—The editor's waste-paper basket—Curious sketches: the Russian censor—Foreign illustrated newspapers.

The lectures will be fully illustrated by lantern slides. An exhibition of drawings will be shown on the walls.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, DEC. 12...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lectures.) Mr. David James Blaikley, "Musical Wind Instruments." (Lecture III.—Reed Instruments, with Musical Illustrations.)

Engineers, in the Theatre of the United Service Institution, Whitehall, S.W., 7½ p.m. Annual General Meeting.

Mechanical Engineers, Storey's-gate, Westminster, S.W., 8 p.m. (Graduates Section) Mr. A. C. Hess, "Gas-Engine Testing."

Chemical Industry (London Section), Burlington-house, W., 8 p.m.

Surveyors, 12, Great George-street, S.W., 8 p.m. Mr. Joseph Jopling, "Notes on Clay Working, more particular Bricks and Tiles."

Geographical, University of London, Burlington-gardens, W., 8½ p.m. Major Delme Radcliffe, "The Anglo-German Boundary Expedition in East Africa."

Camera Club, Charing-cross-road, W.C., 8½ p.m.

Medical, 11, Chandos-street, W., 8½ p.m.

London Institution, Finsbury-circus, E.C., 5 p.m. Mr. G. Clausen, "A Sketch of the Development of Painting."

TUESDAY, DEC. 13...Asiatic, 22, Albemarle-street, W., 3 p.m.

East India Association, Westminster Palace Hotel, S.W., 4 p.m. Sir W. Mackworth Young, "The Progress of the Punjab."

Medical and Chirurgical, 20, Hanover-square, W., 8½ p.m.

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Messrs. Arthur Wood-Hill and Edward Davy Pain, "The Construction of a Concrete Railway Viaduct."

Zoological, 3, Hanover-square, W., 8½ p.m. 1. Hon. Walter Rothschild, "Some Notes on Anthropoid Apes." 2. Dr. W. G. Ridewood, "The Cranial Osteology of the Clupeoid Fishes." 3. Prof. E. A. Minchin, "The Characters and Synonymy of the British Species of *Leucosolenia*."

Colonial Inst., Whitehall-rooms, Whitehall-place, S.W., 4½ p.m. Lieut.-Colonel James Hayes-Sadler, "Present-Day Uganda."

Horticultural, Drill Hall, James-street, Victoria-street, S.W., 3 p.m. Mr. T. Sedgwick, "Fruit Preserving."

WEDNESDAY, DEC. 14...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. Chas. D. Abel, "The Patent Laws."

Biblical Archæology, 37, Great Russell-street, 4½ p.m.

Chemical, Burlington-house, W., 5½ p.m. 1. Mr. V. H. Veley, "Hydrolysis of Ammonium Salts." 2. Mr. A. E. Dunstan, "The Viscosity of Liquid Mixtures." (Part II.) 3. Mr. J. A. Cain, "The Diazo-reaction in the Diphenyl Series." (Part II. "Ethoxybenzidine."). 4. Mr. P. C. Ray, "The Sulphate and the Phosphate of the Dimercurammonium Series." 5. Messrs. R. Meldola and L. Lynon, "A Method for the Direct Production of certain Aminoazo Compounds"

Japan Society, 20, Hanover-square, W., 8½ p.m. Dr. Vaughan Cornish, "Japanese Temples and Monasteries."

Royal Literary Fund, 7, Adelphi-terrace, W.C., 3 p.m.

British Archæological Association, 32, Sackville-street, W., 8 p.m.

British Astronomical, Sion College, Victoria-embankment, E.C., 5 p.m.

THURSDAY, DEC. 15...United Service Institution, Whitehall, S.W., 3 p.m. Mr. W. Kirton, "With the Japanese at the passage of the Yalu."

Royal, Burlington-house, W., 4½ p.m.

Linnean, Burlington-house, W., 8 p.m. 1. Dr. T. W. Woodhead, "The Ecology of Woodland Plants." 2. Mr. C. C. Hurst, "Experimental Studies in Heredity in Rabbits."

London Institution, Finsbury-circus, E.C., 6 p.m. Mr. J. S. Shedlock, "Bird Music."

Mining and Metallurgy, Geological Society's Rooms, Burlington-house, W., 8 p.m. 1. Messrs. R. Arthur Thomas and W. P. O. Macqueen, "The Dust in the Air and the Gases from Explosives in a Cornish Mine (Dolcoath), and the efficacy of methods of dealing with them." 2. Mr. E. F. Harris, "The Permanganate Chlorination Process at Bethanga." 3. Mr. L. H. L. Huddart, "St. David's Gold Mine, N. Wales." 4. Messrs. B. H. Bennetts and L. J. W. Jones, "A New Slag Car."

Optical, 20, Hanover-square, W., 8 p.m. Mr. Brown, "Direct Stereoscopic Projection."

Electrical Engineers, 25, Great George-street, S.W., 8 p.m. 1. Discussion on Mr. Searle's paper, "Studies in Magnetic Testing." Mr. W. P. Adams, "The Combination of Dust Destructors and Electricity Works, Economically Considered."

Historical, Clifford's-inn Hall, Fleet-street, E.C., 5 p.m.

Numismatic, 22, Albemarle-street, W., 7 p.m.

Camera Club, Charing-cross-road, W.C., 8½ p.m.

FRIDAY, DEC. 16...United Service Institution, Whitehall, S.W., 3 p.m.

Royal Institution, Albemarle-street, W., 8 p.m. Weekly Meeting, 9 p.m.

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Students' Meeting. Mr. R. H. Lee Pennell, "Folkestone Harbour: Cylinder-Sinking at the Root of the Old Pier."

College of Physicians, Pall-mall East, S.W., 5 p.m.

North-East Coast Institute of Engineers and Shipbuilders, Newcastle-on-Tyne, 7½ p.m. Mr. James Dickie, "Launch of the U.S.A. Cruiser, *South Dakota*."

Art Workers' Guild, Clifford's-inn Hall, Fleet-street, E.C., 8 p.m.

Quekett Microscopical Club, 20, Hanover-square, W.C., 8 p.m.

Mechanical Engineers, Storey's-gate, Westminster, S.W., 8 p.m. 1. Capt. H. Riall Sankey and Mr. J. Kent-Smith, "Heat Treatment Experiments with Chrome-Vanadium Steel." 2. Discussion on the November paper, "Impact Tests on the Wrought Steels of Commerce."

Journal of the Society of Arts.

No. 2,717. VOL. LIII.

FRIDAY, DECEMBER 16, 1904.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

NOTICES.

NEXT WEEK.

MONDAY, DECEMBER 19, 8 p.m. (Cantor Lecture.) D. J. BLAIKLEY, "Musical Wind Instruments." Lecture IV., (Flutes, with musical illustrations.)

TUESDAY, DECEMBER 20, 8 p.m. (Applied Art Section.) THOMAS GRAHAM JACKSON, R.A., "Street Architecture."

Further details of the Society's meetings will be found at the end of this number.

THE JOURNAL.

The members will have noticed that since the commencement of the present session the number of pages in the *Journal* devoted to miscellaneous matters has been slightly increased. It is intended, from the commencement of the New Year, to continue and to add to this enlargement.

The size of the *Journal* must, as hitherto, vary with the length of the Society's proceedings, which are published each week, but it is intended, as a rule, that the usual number of pages (including advertisements) should, in future, be 32 instead of 24, at all events during the session, and these additional pages will afford room for a larger amount of general information bearing on the objects of the Society.

The estimation in which the *Journal* is held, both by the members and the general public, is well-known, but if the members of the Society, especially those residing abroad, will assist by sending to the Secretary, information of a suitable character for publication, the Council believe that the value and interest of the *Journal* may be still further increased, and that it may be made even more useful to the members than it is.

The Council trust that they may rely on the active co-operation of the members in a matter so essential to the welfare of the Society.

JUVENILE LECTURES.

The usual short course of lectures adapted for a juvenile audience will be delivered on Wednesday afternoons, January 4th and 11th, at 5 o'clock, by Mr. CARMICHAEL THOMAS, Treasurer of the Society, on "The Production of an Illustrated Newspaper."

Each member is entitled to a ticket admitting two children and an adult.

A sufficient number of tickets to fill the room will be issued to members in the order in which applications are received.

Members who desire tickets for the course are requested to apply for them at once.

CANTOR LECTURES.

Mr. D. J. BLAIKLEY delivered the third lecture of his course on "Musical Wind Instruments," on Monday evening, 12th inst. The special subject was Reed Instruments, and musical illustrations were given on the Oboe by Mr. J. L. Fonteyne; on the Clarinet by Mr. Charles Draper, and on the Bassoon by Mr. E. F. James. Mr. R. H. Walthew accompanied the instruments on the pianoforte.

The first lecture of the course will be printed in the next number of the *Journal*.

PROCEEDINGS OF THE SOCIETY.

FIFTH ORDINARY MEETING.

WEDNESDAY, DECEMBER 14th, 1904; ALEXANDER SIEMENS, M.Inst.C.E., Pres. Inst.E.E., Vice-President of the Society, in the chair.

The following candidates were proposed for election as members of the Society:—

Bayley-Worthington, A. B., 8, Balfour-place, Mount-street, W.

Deadman, Thomas W., 58, Northcote-road, St. Margaret's, Twickenham.

Forbes, David, 5, Benedict-road, Brixton, S.W.

Hatschek, Emil, A.M.I.Mech.E., 24, West Twenty-fifth-street, New York City, U.S.A.

Haynes, Josiah Edward, Union Offices Stroud and Paganhill, Stroud, Gloucestershire.

Kerr, Rennie Malcolm, Gokak Falls, Belgaum District, India.

McLaren, William David, A.M.I.Mech.E., Thomason Engineering College Workshops, Roorkee, India.

Mitchell, Arthur Edward, 10, Lower Mount Pleasant-avenue, Rathmines, Dublin.

Nicholls, Captain Alfred Edward, Cotswold, Hornchurch, Essex.

Reynolds, Major James M., Burdett, New York, U.S.A.

Weiskopf, Alois, 3, Sophienstrasse, Hanover, Germany.

Wharton, William Henry, L.R.C.P., 1, Brick dam, Georgetown, Demerara, British Guiana.

Wilson, George Lewis, 522, High-road, Tottenham, N.

The following candidates were balloted for and duly elected members of the Society:—

Chambers, John, Mokopeka, Hastings, Hawke Bay, New Zealand.

Hippisley, Clare Robert, 4, Belgrave-terrace, Bath.

Moorcroft, William, Marsh-avenue, Wolstanton, Staffs.

Owen-Jones, John, Shortmead-street, Biggleswade, Beds.

Peacock, James, 13, Fenchurch-avenue, E.C.

Sapara-Williams, Hon. C., M.L.C., Lagos, West Africa.

Smith, Thomas Strethill, 32, West-hill-road, Southfields, S.W.

Watkins, John, 48, Westbourne-street, Sloane-square, S.W.

Weston, Edward, 645, High-street, Newark, New Jersey, U.S.A.

The CHAIRMAN stated that owing to indisposition Mr. Abel was unfortunately unable to read his paper himself. It would therefore be read by Mr. Abel's partner, Mr. A. G. Bloxam.

THE PATENT LAWS.

By CHARLES DENTON ABEL.

Having regard to the fact that laws relating to the grant of letters patent for invention have now existed in England nearly three centuries, and in some of the other principal States for about 100 years, one would have thought that an experience extending over so large a time would have resulted in some degree of uniformity in the administration of hose laws in most countries, but, curiously to relate, so far from this being the case, there are at the present time no two of the principal States in which any substantial uniformity in this respect exists. There was, however, up to two years ago, a broad line of demarcation which divided the patent laws of the different States into two principal groups, namely, on the one hand, in countries such as England and France, the grant of letters patent was practically unconditional, being only subject to a supervision to insure the compliance of the applicants with certain prescribed rules and formalities, while, on the other hand, countries such as the United States and Germany subjected all applications for letters patent to a rigorous examination as to the novelty of the invention, and refused the grant to all those applications which, in the opinion of the Patent Office officials, did not contain a sufficiently novel invention. This being so, the question forces itself upon one's mind as to which of these diametrically opposite systems is the correct one, or whether they are not both defective in some respect? Now, in order to consider this question properly, it is necessary first to see what are the interests involved that should govern the mode of procedure, and here we find that they are of a two-fold nature; on the one hand, there is the interest of the inventor, who, having made what he considers a valuable invention, and having perhaps spent considerable time and money in practically working it out, naturally desires to reap an adequate pecuniary benefit therefrom by means of patent protection; on the other hand, there are the interests of the community or of the State, which is willing to pay a certain price in order that its industries may benefit by the use of a really good and novel invention, but does not want to pay that price for an invention that is not new. From this consideration, it will be apparent that the indiscriminate grant of patents for inventions is against the interests of the State, and that if there really existed some perfectly reliable and equitable way of determining whether an invention is novel and useful or not, the system of examination in this respect, and of making the grant of a patent dependent upon the proof of novelty, would be the correct one, as an inventor cannot reasonably expect to be put in a position to derive pecuniary benefit by the grant of a patent for an invention which was made by others before him.

But unfortunately there is no perfect system in existence, and in my opinion there never will be. In all the States where this system

of deciding upon the patent ability of an invention is carried out, the practice is full of errors and anomalies; patents are there still granted for inventions that are old, and patents are refused for inventions that are new and valuable, thereby both doing great injustice to the inventor, and also detrimentally affecting the interests of manufacturing industries, inasmuch as an inventor who is refused protection for his invention has no incentive to devote his time and capital to perfecting it and getting it taken up, and the invention may thus be lost to the industry to which it belongs.

Now these defects in the system are mainly due to two causes, namely, firstly, to the fact that power is given to a single examiner, who may or may not be properly qualified, to refuse an application for a patent upon such grounds as he may think fit, and secondly, to the fact that, owing to a system of false economy, the examining staff appointed to do the work is totally inadequate for the purpose, so that an examiner is required in the space of a few hours, firstly, to instruct himself as to the nature and merits of an invention, and then to search in order to ascertain its novelty, with the result that owing to the want of proper time for deliberation, his decisions are as often wrong as they are right, and that he frequently totally misconceives the gist of the invention to begin with. As a proof of the above assertion, I need only point to the fact that both in the United States and in Germany cases are continually occurring where the primary examiner's decisions refusing the grant of a patent are reversed on appeal, a fact which I believe every patent agent in even moderate practice can confirm. It may, of course, be argued that as there exists this safeguard of appeal, there is no great harm done by the primary examiner's rejection. and if every inventor were a man of means, and in a position to employ a competent professional adviser in prosecuting his application for a patent that might be so. But, unfortunately, a very large proportion of inventors are not men of means, and, in consequence, not being able to afford the fees of a competent professional adviser, they either prosecute their applications themselves or employ some unqualified person for the purpose. As a result, when the primary examiner refuses the application of such an applicant, the latter may either believe the fallacious arguments of the examiner, and, consequently, abandon his application, or he may be prevented by lack of funds from going to the expense of an appeal.

In order to show that my statements as to the detrimental effects of the United States and German systems are not imaginary, I will first refer to a case that has lately occurred in the practice of my firm in respect of an invention of some importance, which, being about to be introduced on a large scale, may possibly interest my hearers. In the year 1901, Messrs. Vogt and von Recklinghausen applied for a United States patent for a method of and apparatus for producing motive power by causing an explosive charge to force a body of water into a chamber where it was stored at high pressure, and whence it was taken for working hydraulic motors. In order that the proceedings before the United States examiner may be thoroughly understood, I will describe broadly the construction and action of the machine for this purpose, referring to the diagram on the wall. In this diagram, which only shows the main operative parts of the machine, there is a cylindrical compression and explosion chamber, the lower end of which is surrounded by an annular chamber, wherein water is stored at a comparatively low pressure, the pressure being exerted by a cushion of compressed air in the upper part of the chamber. This low pressure chamber is adapted to communicate with the first chamber through openings which are, however, normally closed by means of a piston having passages through it controlled by a self-acting lift valve. Above this second chamber is another annular chamber which is adapted to communicate with chamber 1 through openings which are normally closed by a self-acting lift valve. This chamber 3 contains water subjected to a high degree of pressure by a cushion of compressed air at top. The chamber has an inlet for explosive charges, a discharge valve for the combustion gases and an air supply valve. The three chambers being filled with water to about the extent shown, the action of the machine is as follows: Assuming the upper part of chamber 1 to have been filled with air through the valve an explosive charge is admitted through a nozzle controlled by a suitable valve. Hereupon the piston is raised by mechanism, not shown, sufficiently to uncover the openings, so that the water contained in chamber 2 is forced through the said openings, and through the valve of the piston into the chamber 1, thereby forcing up the column of water therein and thus com-

pressing the explosive charge. This is then fired, and the resulting explosion drives the column of water through the openings into chamber 3, thus compressing the air-cushion to a greater extent and consequently subjecting the water to a higher degree of pressure. The water in chamber 1 having thus again sunk to about the level indicated, the escape valve and air valve are both opened and a scavenger blast of air is made to drive the combustion gases off. On the occurrence of the explosion, the piston and valve are forced down into their original position, shutting off the communication between 1 and 2. The water under high pressure stored by the above action in chamber 3 is led off through a pipe to any suitable hydraulic motor, the discharge from which, still under a certain pressure, is led back through a pipe into chamber 2 to replenish its store. The piston being again raised, the above-described action is repeated, and so on continuously. It will thus be seen that apart from the construction of the machine there is a two-fold action of the liquid, first in being forced up in chamber 1 so as to compress the explosive charge, and, second, in being forced by the explosion into the chamber 3. In the claims originally made in the specification of the United States application, the above-described action of the liquid was referred to in setting forth the construction of the machine. These claims were, however, objected to by the examiner as being "functional," under a peculiar rule of the United States Patent Office, which I have formerly explained in my letter in the Society of Arts *Journal*, July 29th, 1904. Separate claims for the method of operating were then drafted and submitted to the examiner, who, under another peculiar rule of the office (which has since been declared *ultra vires* by the Supreme Court in the case of Steinmetz *v.* Allen 1090 G 549, of which particulars are given in Appendix No. 4) refused to allow these claims to be included in the same patent with the claims for the apparatus, in consequence of which the inventors, acting under my advice, filed a separate application for the method of operating, in which the claims required to be so worded as to avoid all mention of the apparatus (in compliance with another peculiar rule of the office) as the following claim, which I quote by way of example, will show:—

"That improvement in the art of producing liquid under pressure which consists in providing a body of liquid under a head for performing work, and a second body of liquid under a lower head, which is made to compress an explosive charge, and causing the explosion of such charge to act upon a portion of the liquid of lower head and cause it to replenish the liquid under the higher head, substantially as described."

After various communications had passed between the examiner and my firm's representative at Washington upon the question as to whether there was a patentable method involved in this new application or not, the examiner finally refused to allow the patent, stating, "It is still thought, particularly in view of the Supreme Court decision in Busch *v.* Jones, that the alleged method presented by the claims is the mode of operation of the apparatus employed." My clients then appealed against this decision before the Board of Examiners in Chief, with the result that the examiner's decision was reversed and the patent was granted. As the Examiners in Chief's ruling on the question of the method claims being patentable or not is of considerable interest to inventors and patentees generally, I have given it in full in Appendix No. 1, as it would take too long to quote it here; I will only give here the first sentence as showing how emphatically they declared the primary examiner to be in the wrong:—

"As to the ground of rejection on the alleged absence of true method claims, the validity of these claims as true process claims under the decision of the Courts is too plain to admit of discussion."

It will be seen, from what I have stated, that in the first instance, the examiner obliged my clients to take out two patents instead of one, thus causing them double expense, and this on account of a rule of the Patent Office which, as before stated, has since been declared *ultra vires*; secondly, in denying the existence of a patentable method he put them to the additional expense of appealing against his decision.

Had my clients been of limited means, or had they been badly advised, they would probably have accepted the examiner's decision as final, and would thus have lost the most valuable part of their invention, because the apparatus for carrying out the method of operating could be constructed in various other ways than that which was covered by their second patent.

Many cases similar to the above could be quoted, both before the United States and the German Patent Offices, where the adverse decision of the examiner has been reversed on appeal, but it would lead too far to go

into these here. In Appendix 2, I have given a further case before a United States examiner, and in Appendix 3, I have given a case before a German examiner, in which he rejected an application simply because he quite misunderstood the purport of the claims. A further instance of the prejudicial effect that the action of a United States examiner may have upon the interests of an inventor, will be found in Appendix 4, which gives an abstract of the judgment of the United States Supreme Court in the important case of Steinmetz *v.* Allen, from which it will be seen that it took the petitioner *over seven years* to vindicate his rights, owing to the improper decision of the examiner, in refusing to allow him to appeal from the examiner's decision to the Board of Examiners in Chief.

How seriously the above system of examination, as carried out in Germany, operates against the interests of the inventor will be evident on considering the above Table, published by the German Patent Office, showing the number of patent applications and number of patents granted during the years 1901, 1902, 1903, particularising the applications made by the German inventors, and those of the inventors of all the other States. It will be seen from this Table, that the total average percentage of patents granted is only 38·5 per cent. of the applications, while for Germany alone the average only amounts to 34·2 per cent. (in 1903 it was only 30·9 per cent.), in other words, it shows that out of every three applications for a patent practically two are refused. It will also be seen from this Table that, with the exception of one or two minor States the proportion of rejections have gradually increased from 1901 to 1903—in the case of Germany from 63 per cent. to 70 per cent.

No one who has had much to do with patents for inventions would be prepared to say that the proportion of old inventions to new ones is anything like so large as this. From my own experience, extending over about 45 years, I should put the proportion in cases that have come before me, roughly at about one old invention to five or six new ones. Unfortunately no such Table as the above is published in the United States reports, but the latter give the number of applications for patents in the year 1903 at 49,289 and the number of patents granted at 31,046; that is to say 63 per cent. of the applications, or approximately double the percentage granted in Germany. Referring again to the Table, it may be as well to point out that this entirely dispels the erroneous idea entertained by many English patentees, that great favouritism is shewn in the German Patent Office to German inventors to the detriment of foreign inventors. It will be seen that the average percentage of patents granted to German applicants is only 34·2, while the percentage granted to United States applicants is 59·4, and the percentage of patents granted to English applicants is 54·1, so that as a matter of fact, the German inventors come much worse off than the foreigners.

I think that on considering the facts which I have given it will be generally conceded that

Patents Applied for and Granted in Germany, 1901-2-3.

my assertion that the system of examination as carried out by the United States and Germany is highly prejudicial to the inventor, is perfectly justified, and this being so, the question arises, is it not possible to devise some system intermediate between that of the indiscriminate grant of patents, and this very objectionable one, that would fairly satisfy the interests of the inventor and those of the community?

Now, fortunately, such a system *can* be devised, and was in fact proposed by me some forty years ago, and it is a matter of wonder to me why it was not until the year 1901 that our Government could be persuaded to take it into consideration and finally embody it in the Patents Act of 1902. This system, which is to be put in force by the Patent Office on the 1st January, 1905, consists shortly in this, that on an applicant lodging a complete specification at the Patent Office, a full and careful search shall be made by the examining staff among all patents taken out within the last fifty years, in order to ascertain whether the invention claimed is really new. If a prior patent should be found which, in the opinion of the Comptroller-General, more or less anticipates the invention, the applicant is to be apprised of this, and it is open to him either to amend his specification if he is convinced of the correctness of the assertion, or to argue against the Comptroller's opinion. If after hearing his arguments the Comptroller is still of opinion that the applicant is anticipated by the prior patent, he has the power, subject to an appeal to the Law Officer, to cause a reference to be inserted in the specification to the prior patent or patents in question. Thus any intending licensee under or purchaser of the patent is at once made aware of the alleged anticipation, and is put in a position to decide for himself what may be the value of the patent in the face of the prior publication.

I think it will be agreed that this system is a perfectly equitable one, as it still leaves the inventor perfectly free to take out his patent for whatever it may be worth, while, at the same time, it prevents him from imposing upon the public with a bogus patent. As long ago as the year 1855, in a paper that I read before the Society of Engineers, I very strongly advocated this system and, among other arguments, I stated as follows, in referring to the question of the novelty of inventions:—

"Of this, and of the other points, a duly qualified Board of Examiners would be quite competent to judge; they should, however, only have the power of absolutely refusing applications, the alleged inventions of what were based upon assumptions obviously at variance with known physical or mechanical laws, while in all other cases where their opinion differed from that of the inventor, the matter should be referred to a patent tribunal to which the inventor should, under any circumstances, have the power of appealing; and if the opinion of the examiners were endorsed by this tribunal, it should be appended to the specification of the patent."

It will be seen that the mode of procedure now adopted is based exactly upon these lines. The important question now arises, however, as to the manner in which the system is going to be carried out so as to be perfectly just to the inventor. This practically resolves itself into a question as to the amount of money that is to be spent for this purpose, that is to say, it depends on the one hand upon whether a perfect system of classification of inventions is to be provided, which will enable the examiners to ascertain in the shortest possible space of time all prior patents that may bear upon the invention of an applicant, and, on the other hand, it depends upon the number and quality of the examining staff that is to be employed upon this work. If money is to be stinted on either of these heads, then it would be far better to abandon the system altogether. Now both in the United States and in Germany, a system of parsimony prevails in this respect. It is true that in the United States a fairly perfect system of classification of inventions has been worked out, but as regards the examining staff the number of men engaged on the work is ludicrously inadequate, and this remark applies equally to the German Patent Office, as will be shown from the following data. Referring in the first place to Germany, there were in the year 1903, 28,313 applications for patents which had to be dealt with by an examining staff numbering 217. This gives as the work of each individual examiner an average of 130 applications to be dealt with in the year. As I am informed that there are about 1,940 official working hours in the year in Germany, this will give an average time of about 15 hours, during which the examiner must completely deal with one invention; that is to say, he must first thoroughly study the invention, he must then make a complete search as to novelty, and must argue the case at length with the applicant, involving in many cases a long correspondence and reconsideration of amended specification, claims and drawings, before he can come to a final decision respecting the application. All this

would have to be accomplished in the before-mentioned average time of 15 hours, a task which anyone acquainted with this class of work will admit to be a perfectly impossible one. In the United States the case is still worse; here, there were in 1903 no fewer than 49,289 applications for patents that had to be dealt with by an examining staff numbering 261, giving roughly 190 applications to be dealt with by one examiner in the year. The number of official working hours in the United States is about 1,911, thus giving an average time of ten hours for an examiner to deal with one application. Now the result of this very inadequate time allowance is, that the examiners do not, and simply cannot, efficiently do the work that is supposed to be carried out by them.

The applicant's invention is not carefully studied by them, and, as a consequence, is frequently entirely misunderstood; also, instead of making a careful search, and only drawing the applicant's attention to those prior patents that really more or less anticipate his invention, they simply pick out all patents that deal with the class of invention in question, and practically say to the applicant, "All these, in my opinion, anticipate your invention, prove to me that they do not." The unfortunate applicant then has to wade through perhaps a dozen or more specifications in order, possibly, to find that the majority thereof in no way relate to his invention at all, and that this is not anticipated by any one of them.

I am sure that anyone who has had to deal to a considerable extent with the United States and German Patent Offices, will bear me out in this statement. In order to give some idea of the inadequacy of the United States and German examining staffs for tho work they have to perform, I have requested one of the searchers employed by my firm to ascertain the average time occupied in effecting a search as to the novelty of an invention, for which purpose he has taken all searches made by him between June, 1903, and June, 1904. There were in all 31 searches which occupied altogether 2,440 hours, giving an average of 80 hours for each search. In comparing this time with the figures before stated, however, it is necessary to take the following points into consideration. Firstly, the searcher happened to have no searches of very short duration during that year, which would have reduced the average, the shortest one occupying 21 hours, and secondly, the patent office indexes and illustrated abridgments were the only means available to the searcher, while the official examiner would have his specially prepared detailed classifications of inventions to help him. Taking these points into account, I would be willing to put the average time of an examination and search, to be properly carried out by the Patent Office examiner, at a much lower figure than my searcher's average, say about 30 hours as compared with 15 hours and 10 hours now allowed respectively by Germany and the United States.

If my estimate is correct, then it would appear that the German staff should be at least doubled, and the United States staff trebled; I say "at least" because it should be stated that the work of the searcher in question would end with reporting to his employers the number of prior English patents relating to the invention found by him, and would not include the considerable additional work of searching among foreign patents and other publications. of carefully examining the patents and publications found, and subsequently reporting thereon, which the foreign official examiners have to do.

I now come to the important question as to what our Patent Office proposes to do when starting upon the new system. I am informed that the Comptroller-General proposes to start with an examining staff consisting of 24 chief examiners, 24 deputy examiners, and 131 assistant examiners, making a total of 179 examiners.

Taking the number of complete specifications to be examined in one year at 15,821, that being the number filed in 1903, this will give 88 specifications to be dealt with in one year by each examiner. Assuming the number of official working hours to be 1,430, that being the number given by the Comptroller-General in the official report of 1901, this would give 16 hours as the total time an examiner could devote to one application.

The next Table shows the above quoted data for the United States, Germany, and England, from which it will be seen that with the proposed staff of 179 examiners the system would be no more perfect than it is in Germany. It may be that the Comptroller-General only proposes this number to begin with and intends to increase it gradually as the work increases, and this would be right enough, because of course the full number of applications to be examined would only be reached at the end of the first year. I fear, however, that this is not

his intention, because in the report of 1901, when speaking of the results of the trial search which the Comptroller had had made, he gives it as his opinion that one examiner could deal with 111 applications in the year, which would give an average of only 13 hours for each case.

In considering this point it is to be observed that the work of examination in respect of English patent applications will be much heavier than either in the United States or Germany, for the following reasons :—

Applications for English patents contain as a rule a very much greater amount of subject-matter than is the case with United States and German applications, because, as is well known, the idea of what constitutes one invention is very much more limited in those States than in Great Britain. This is proved by the fact, that when United States inventions are sent over here to be patented, it is quite a common occurrence for the subject-matter of several of these to be included in one English patent. This was the case, for example, with a series of patents relating to mechanical cashiers, which I had under consideration some time since, one of which, No. 2130 of 1902, contained the subject-matter of four United States patents, and consisted of 21 pages of text, and 23 sheets of drawings. The apparatus described simply bristles with minute and complicated details, all of which were claimed and would have to be separately searched for by the examiner. How long it would take an examiner to deal properly with this specification, I should be afraid to say. This is by no means an exceptional case, a large number of similar patents, mostly of American origin, being taken out every year; to give another example, there is a patent, No. 2302 of 1902, on the subject of golf balls, which includes the subject-matter of no fewer than *nine* United States patents and contains 51 claims.

Thus, it will be seen that the English examiner who had to deal with this patent would have to do the same amount of work as the United States examiner expended on the examination of nine United States patents.

Here I may, parenthetically, draw attention to another example of the old story of English liberality in dealing with subjects of foreign States and the illiberality of those States in dealing with English subjects. While our Patent Office allows any number of United States or German patents to be combined in one English one, the Patent Offices of those not only do not allow this, but, owing to their peculiar views as to what constitutes one invention, they actually require a large proportion of English specifications to be divided up into a number of separate applications; thus, for example, my firm was obliged to divide the subject-matter of the English Patent No. 15286 of 1885 for the well known Welsbach incandescent light, into five United States applications, while another patent on the same subject, No. 3592 of 1886, had to be divided into four United States patents. Again an English patent for a typewriting machine had to be divided into five German patents, even after abandoning several of the improvements, thus involving the patentees in an expenditure of £1,312 10s. for keeping up these patents as compared with the cost of £99 for the British patent. It is a question, therefore, whether something should not be done in the way of retaliation, by our Patent Office refusing to allow more than one foreign patent to be included in one British patent.

In the new rules lately issued by the Board of Trade, some general provision has been made in this direction by the statement that

TABLE SHOWING THE AVERAGE TIME ALLOWED AN OFFICIAL EXAMINER FOR SEARCHING AS TO AND DETERMINING THE NOVELTY OF AN INVENTION.

Country.	Number of applications to be examined in 1903.	Number of examining staff.	Number of applications to be examined by one examiner in one year.	Official working hours in a year.	Average time afforded an examiner for dealing with one application.
United States	49,289	261 (*a*)	190	1,911	10 hours.
Germany................	28,313	217 (*b*)	130	1,940	15 hours.
Great Britain............	15,821	179 (*c*)	88	1,430	16 hours.

(*a*) Composed of 38 Chief Examiners, 42 First Assistant Examiners, 50 Second-class, 61 Third-class, 70 Fourth-class.
(*b*) Composed of 86 Chief Examiners, 131 Assistant Examiners.
(*c*) Composed of 24 Chief Examiners, 24 Deputy Examiners, and 131 Assistant Examiners.

"when a specification comprises several distinct matters, they shall not be deemed to constitute one invention by reason only that they are all applicable to or may form parts of an existing machine, apparatus or process," which rule, however, will of course apply not only to such cases as I have mentioned, but of view. Thus, on the one hand, in the United States a patentee is allowed to include in one patent several separate improvements on one and the same machine, but if an invention is capable of being carried out in variously modified ways and it is necessary to claim each of those modifications separately in order

Table Shewing the Divergent Views of the U.S.A. and German Patent Offices in the matter of Patentable Inventions.

	What constitutes a patentable invention.	*What is allowed to be included in a patent as one invention.*	*What form the claims are required to take.*
United States.	Any combination of devices that is substantially new is patentable. Such new combinations need not necessarily possess any particular technical advantage over similar-known combinations.	Several improvements relating to the same machine may be included, although they may not be dependent upon each other. Modification of an invention, if required to be claimed separately, have to form the subject of separate patents.	Claims for apparatus or machinery may consist o' a mere enumeration of the parts constituting a new combination without any statement of their relation to each other. Claims of a "functional" nature, *i.e.*, setting forth the operation, effected by the several parts of a machine enumerated are not allowed.
Germany.	A new combination of devices, no matter how different from known combinations for the same purpose, is not considered a patentable invention, unless it can be shewn that a substantially new technical advantage is derived therefrom. A very small modification of a known device, method or process, can constitute a patentable invention, provided it is shewn that a substantially new technical advantage is derived therefrom.	Several improvements relating to the same machine cannot be included in one patent unless they are necessarily dependent upon each other in their functions. In a patent for a substantially new machine, apparatus, or process, there may be included separate claims for modifications thereof.	Claims merely setting forth a combination of devices, without any statement as to how they operate, are not allowed. Claims are required to be of a "functional" nature, *i.e.*, they must set forth the operation of the parts enumerated.

generally to all patent applications, and the difficult question will arise as to the proper definition to be put upon the term "one invention." As I have before mentioned both the United States and the German Patent Offices have put a very strict interpretation upon this term, but, curiously enough, the rules in this respect are based upon totally different points to properly secure them, the Patent Office looks upon each such modification as a separate invention and consequently the inventor is obliged to take out a separate patent for each one.

In Germany, on the other hand, the applicant is allowed to include several modifications of an invention in one and the same

patent, but if the invention relates to several improvements in one and the same machine, which improvements have no direct relation to each other, then the German Patent Office says, that each of these improvements is a separate invention, requiring a separate patent. The German and United States Patent Offices are equally divergent in their views upon all other questions relating to patents, and by way of curiosity I have exemplified this on the preceding Table.

As an example of the lengths to which the German Patent Office will go, in subdividing inventions, I cited a case in my letter in the Society of Arts *Journal* of the 26th February, 1904, in which my clients were required to take out two separate patents for improvements in connection with one and the same lever device, because an improvement relating to means for connecting the one end thereof was not necessarily applicable in combination with another improvement relating to its fulcrum. Our Patent Office has hitherto taken a view which is equally divergent from both the United States and the German views on this question of one invention. The Comptroller has allowed a number of different improvements in one machine, and also several modifications of the same to be included in one patent, but when a certain improvement was claimed to be applicable to another class of machine, he has held that this was a separate invention requiring a separate patent.

From the paragraph which I have before quoted from the new rules, it would appear that the Comptroller is now going to adopt a definition similar to the German one, but let us hope that he is not going quite so far in this direction as in the instance which I have cited.

As I have before stated, the efficient carrying out of the new system depends probably quite as much upon a proper classification of the inventions as upon the number and quality of the examining staff.

The search as to the novelty of an invention is obviously enormously facilitated, if one has close at hand a complete synopsis of all prior patents in any way relating to the invention in question.

Now the most perfect system of classification in existence is probably that carried out by the United States Patent Office.

In this office, the subjects of invention are divided into 235 classes, and these classes are distributed among 38 examining divisions of the office. The plan according to which the different subjects are distributed among many of these divisions is somewhat perplexing, for example to division 5, we find allocated book-binding, fine arts, harvesters, jewellery, and music, and it is somewhat difficult to see how the examiner in charge of this division can be thoroughly at home in such diverse subjects as book-binding, harvesters, and music. Again, in division 25 we find such heterogeneous subjects as artesian and oil wells, butchering, mills, stoneworking, threshing, and vegetable cutters and crushers.

Furthermore, seeing that all other subjects relating to agriculture are included in division 1, it is difficult to understand why harvesters are put in division 5, and threshing-machines in division 25.

Division 20 again includes the various subjects of artificial limbs, builders' hardware, dentistry, locks and latches, safes and undertaking. However, it may be supposed that the chief examiner in charge of the division has under him assistant examiners, each of whom is more particularly conversant with one or more of the classes of the inventions in that division that are of a cognate nature. The several classes enumerated in each division are again divided into a large number of sub-classes, which, for example, in class 144, relating to wood-working, amount to over 300, each of which sub-classes relates to some special detail of a particular kind of wood-working instrument. Thus, for example, if the subject-matter of an application relates to a special kind of boring tool, the examiner finds to his hand no less than 21 classifications of tools or devices that come under this heading, and he can at once put his hand upon all the patents that relate to a boring tool of the nature of the invention in question.

But however complete this system of classification may be, it still does not, in my opinion, go far enough. There are a considerable number of inventions patented every year that include new or improved devices which are applicable generally to a great variety of machines or apparatus, and that may be termed "machine elements;" such for example as valves, levers, cranks, eccentrics, differential motions, stuffing boxes and other packings, &c., and these are frequently hidden away in machines or apparatus where one would scarcely expect to find them. Thus, I had before me a short time ago an invention relating to a flying machine, part of which consisted in a very novel and ingenious construc-

tion of sun and planet mechanism that might be applicable to a number of other purposes; also an invention relating to machinery for the manufacture of boot-lasts, which contained a novel construction of regulating valve for the hydraulic actuating mechanism, which was covered by a substantive claim. Now, there is provided in the United States classification a class No. 74 for machine elements which is allocated to division 12, and any patent that relates solely to a certain machine element would be referred to that division and class, in which, however, I may remark there is not included a sub-division for either valves, pistons, or a number of other common elements; the above-mentioned last-making machine, however, would be allocated to division 29, class 145, for wood-working apparatus and the examiner of that class on searching, and not finding, a prior patent anticipating the subject-matter of the claims, would report to that effect, and the patent would be granted in due course, although there might possibly exist a prior patent relating to an entirely different class of machine which contained exactly the same construction of valve as in the patent mentioned, and the publication of which would consequently invalidate the substantive claim for the valve made in the last-machine patent.

In order to remedy this imperfection, I would propose the following. A separate class should be established not merely generally for machine elements, but for every separate machine element, such as those I have before referred to, and the specification of every patent relating to machinery should be carefully analysed to see if it contained any new or improved machine element, and in the event of there being such, it or they should be entered into the corresponding class or classes.

Every division of the examining staff should then be supplied with a set of these classes for machine elements, so that, for example, the examiner in the before-mentioned class 145 for wood-working apparatus, after having examined all patents relating to last-making machinery, would then have to refer to the particular class for valves, in order to ascertain the novelty of the construction of the valve in question.

Now, no doubt the carrying out of such an elaborate analysis of all patents—and the before-mentioned required great increase in the examining staff—would entail a very considerably increased expenditure in the Patent Office, to which our Government would no doubt object, but I say that in view of the great advantages that would be derived therefrom, both by inventors and the public generally, that increased expenditure ought to be insisted upon. There has, in fact, been a great deal too much false economy practised heretofore by the Government in respect of the Patent Office, and this from the simple fact that neither the Government nor the public has ever estimated at its true value the great debt this country owes to inventors and their inventions. The British public accepts, as a matter of course, every new invention that is brought before it. It knows nothing of the toil, the expenditure of capital, the hard brain work to which inventors subject themselves in order to bring those inventions to perfection, and, consequently, it does not feel particularly grateful to them.

We delight to honour our great statesmen and warriors, even to the extent of decorating their statues annually, but who dreams of doing honour to our great inventors? Yet where would the former be without the latter? Where, I ask, would be the present widespread state of mental culture but for the invention of paper and the printing press? Where our great maritime commerce and our magnificent colonial possessions across the seas had it not been for the invention of the mariner's compass? Where, again, would be our great manufacturing industries and the commercial prosperity arising therefrom, but for the inventions of men such as Watt, Crompton, Arkwright, Stephenson, Huntsman, Whitworth, Fairbairn, Bramah, Bessemer, Siemens, and a host of others? Here, no doubt, many will say: Granted that these men deserve well of the nation, but they had their reward in the fortunes they made out of their patent rights.

No doubt some of them did so, but also many of them certainly did not; it is a well-known fact that many notable inventors died in poverty, and that it was only the manufacturers, who afterwards adopted their inventions, who made money by them. And even of those inventors who eventually did reap pecuniary benefit from their inventions, many, in their enthusiastic belief in their inventions, had spent almost their last penny in costly experiments before they attained success.

It is well-known that the late Sir Henry Bessemer spent nearly the whole of his capital upon his invention before he was rewarded with success. Again, the late Sir William Siemens himself told me that he had spent

over £10,000 upon his regenerative furnace invention before it was commercially successful.

Thus, it is as much the indomitable courage and perseverance of these inventors, as their inventive genius, that should command our admiration and gratitude.

If then we owe so much to inventors, without adequately recognising their merits, let us at any rate do full honour to an institution that may well be considered as the representative of their genius and labours. Let us make the Patent Office as perfect a technical institution as it is possible to be, thoroughly equipped in every respect for carrying out the duties it has to perform.

The German Empire, with its comparatively limited finances, is now spending nearly a million sterling upon a new patent office of palatial proportions; if we are content to forego such magnificence, let us at any rate not grudge a few thousands for perfecting the administration of our Patent Office. At the present day, considerably over £100,000 surplus income derived from the pockets of inventors flows annually from the Patent Office into the coffers of the Treasury. Every penny of this money and as much more as may be required should be expended in carrying out the most perfect system imaginable for enabling full justice to be done to the interests of inventors and the manufacturing community; and be it said that the Patent Office might advantageously take upon itself functions going far beyond the mere work of carrying out the Patent Laws. In this respect I will venture to quote another paragraph from the above-mentioned paper which I read before the Society of Engineers in 1865. After pointing out how, in my opinion, the work of indexing and classification as it was then carried out by the Patent Office should be improved, I went on to say—

"But besides completing and perfecting the information at present afforded by the Patent Office, its functions as technical guide and purveyor of useful knowledge to the inventor and to the public generally, might, with advantage, be greatly extended. The Patent Office should constitute a perfect technical encyclopædia. The inventor should then be able to obtain a complete knowledge not only of patented inventions, but of all and everything appertaining to arts, science, and manufacture that exists.

"No pains should be spared, no expense shunned, to procure, to sift, to classify the required information, and to put it in the hands of the inventor in such a form that he could readily make use of it. The proper fulfilment of such a task would be a noble object for the Patent Office, and would raise it to the level of one of the first institutions of the land. . . .

"A staff of competent officials should be appended to the Patent Office, whose duty it would be to travel about, both at home and abroad, and collect all such common knowledge, forwarding it to the Patent Office to be there digested and classified and put in a useful form before the public."

To those who would smile at the idea of going to the expense of sending a roving commission to other countries for the purpose of picking up useful information, I will only say that *this is precisely what the Germans did more than* 50 *years ago.* When I was a student at the then most important German Government Engineering and Technical College at Carlsruhe in Baden, during the years 1848-52, there already existed in the college portfolios upon portfolios of large scale drawings obtained by this means of English railway plant, detailed drawings of English locomotives and drawings of machinery obtained, goodness knows how, from some of our largest engineering establishments. The trouble thus taken by the Germans in those early days to afford the youth of the country a thoroughly scientific and technical education, has stood them in good stead, and quite explains the marvellous advance of German engineering and technical industry, which has now become such a formidable rival to England. We, on the other hand, in our insular pride and self-sufficiency, have all along scorned to take the trouble of ascertaining what was doing in scientific and technical matters in other countries, and as a consequence we have now been left behind in the race.

There yet remains another important point to be considered in connection with the new system of examination, namely, the question as to what will be the best course to pursue in carrying out the Act of 1902 for "giving notice to the public of any prior patents that in the opinion of the Comptroller-General more or less anticipated the invention," in those cases where the applicant refuses to refer to them in his specification.

Three modes of carrying out the said provision present themselves to one's mind; the simplest and most obvious would of course be, for the Comptroller merely to add a memorandum to the specification stating that such and such prior patents should be referred to when considering the particular invention; the second would be for the Comptroller to add to this statement his opinion as to how the said

patents affect the invention in question; and the third would be for the Comptroller merely to refer the public to the record of the proceedings in the matter before the examiner and the Comptroller. Now, according to the new rules, the Comptroller proposes to proceed according to the first system, and this would, in my opinion, be objectionable, because it might operate very prejudicially to the interests of the patentee, inasmuch as anyone contemplating taking an interest in the patent in examining the specification, and seeing possibly a long array of prior patents quoted against it, would in most cases be at once prejudiced against the patent, and decline to have anything to do with it.

The second system would be less prejudicial to the patentee, but to be equitable, it might entail a very long statement on the part of the Comptroller, and therefore cause a considerable expenditure of official time that could ill be afforded. The third system, which is similar to that proposed in a paper read by me before the International Association for the Protection of Industrial Property, is, in my opinion, the most practical and most equitable to the patentee. According to this, the complete record of the proceedings before the examiner and the Comptroller should be open to the public, who, on application should be able to obtain a copy thereof, as is the case in the United States Patent Office, where the system is very largely availed of, not only in connection with United States patents, but also in connection with the corresponding English patents, for the purpose of ascertaining whether the validity of the latter is in any way affected by what was disclosed by the United States Record. This information would put anyone interested in full possession of all the arguments both for and against the validity of the patent, so that he or his professional adviser could draw their own conclusion on this point.

Whether the Comptroller-General is at liberty to pursue this course in view of the wording of the Act which says that the Comptroller "shall . . . . determine whether reference to any, and if so, what prior specifications ought to be made in the specification," may be an open question, but it seems to me that if he referred to the record which sets forth the specifications in question this would amount to a reference to those specifications in compliance with the above clause.

A last remark I have to make refers to Section 7 of the new rules. This section provides that as soon as an examiner on commencing his search, finds that the invention has been wholly claimed or described in a prior patent, he shall at once make a provisional report to the Comptroller without proceeding further with the search, and if the Comptroller finds the examiner's opinion to be correct, the application shall be dealt with as provided by sub-section 6 of the Act of 1902; that is to say, the Comptroller may at once make a reference in the specification to the anticipating patent found. Now it may happen that if the examiner had continued his search to the end, he might have found one or more other patents that anticipated the invention more completely and indisputably than the one cited, and thus anyone desirous of taking an interest in the patent, and who might not agree with the Comptroller as to the completeness of the anticipation by the patents cited, would not be put in full possession of the facts on this point. The question of what constitutes a complete anticipation of an invention frequently turns upon such small differences between the two inventions, that the Comptroller and the law officer not being experts in the particular industry or art, might well overlook them, if the applicants fail to point them out. In view of this possibility, although the Comptroller proposes to inform the public that the reference is made in consequence of a provisional investigation only, I think that even when there is only the slightest and apparently unimportant difference between the two inventions, the search should be continued to completion.

In conclusion, I may be allowed to recapitulate shortly the main points which I have endeavoured to bring out in this paper.

I say firstly, that the system of examination with power given to the examiners to refuse the grant of a patent on the ground of alleged want of novelty as carried out by the German and United States Patent Offices, and those of many other countries, is detrimental alike to the interests of the inventor and to those of the State; that even admitting the system to be correct in theory, it is not practically possible to carry it out in such a manner as to be perfectly equitable to the inventor whilst safeguarding the interests of the community; that to attempt to carry out the system with the very inadequate staff at the command of the Patent Offices of those States constitutes a great injustice to the inventors.

Secondly, that it is an injustice to the inventor to oblige him to go to the expense of an appeal from the decision of a primary examiner; that when the views of the examiner differ from

those of the inventor it should be the duty of the former to lay the matter before the higher authorities, and only if these confirm his decision should the inventor be called upon to argue the case further. This, I am glad to notice, is the system provided for by the new rules of our Patent Office.

Thirdly, that the correct system of examination is that about to be adopted by the English Patent Office under the Act of 1902, always provided that an adequate examining staff be appointed and that the most perfect possible system of classification of the inventions be established for enabling the work of searching to be carried out in a perfectly efficient manner, so that the inventor shall not be put to unnecessary trouble in having to prove the novelty of his invention.

Lastly, that the Patent Office instead of being, as it now is, a mere branch of a second-rate Government Department, should be elevated to the position of an independent Government Department, directly responsible to the Cabinet and Parliament, as constituting the worthy representative of one of the main sources of England's greatness and prosperity.

APPENDIX I.

Vogt and Recklinghausen's Invention.

Ruling of the Examiners-in-Chief upon the decision of the primary examiner rejecting the application.

As to the second* ground of rejection, the validity of these claims as true process claims under the decisions of the Courts, is too plain to admit of discussion. See Cochrane *v.* Deever, 94, U.S. 780, 792, where the claim was:—

> "The hereinbefore described process for manufacturing flour, and then taking out the pulverulent impurities by subjection to the combined operations of screening and blowing, and afterwards re-grinding and re-bolting the purified middling."

J. K. Williams Co. *v.* Miller and Co., 970 g., 2308, where the claim was:—

> "The process herein described of applying a cigar wrapper to and around the filler, which process consists in holding the wrapper, by air pressure, flat on a perforated table, and in thereupon gradually rolling it around the filler, the unrolled portion being meanwhile held to the table by air pressure, substantially as specified."

In *re* Weston 940 g., 1786, C.D. 1901, p. 290, where one of the claims was:—

> "1. The described method of manufacturing a symmetrical movable coil for an electrical measuring instrument, consisting in first forming a supporting frame or spool by subjecting a short tube of metal to pressure until the desired conformation and shape is obtained, then winding the coil thereon and finally securing the pivot pins thereto in the axial line of the coil."

The Court also said:—

> "It seems to us from all these authorities the deductions to be drawn are the e:—First, that processes involving a chemical or other elemental action, if new and useful, are patentable; second, that a process, which amounts to no more than the function of a machine, is not patentable; third, that a process or method of a mechanical nature, not absolutely dependent upon a machine, although perhaps best illustrated by mechanism, may, if new and useful, be the proper subject of a patent, even though it involves no chemical or other elemental action."

Even though it be admitted that the result of the step of compressing the explosive mixture by a liquid piston is the same as if that compression had been effected by a solid piston, yet, in the former case, no moving mechanism is employed, and the intrinsic character of the step is clearly of the same character as the pneumatic steps in the first two cases above stated.

The question whether there is or is not a true process in these claims is determinable by the answer to the question whether there is any force operating it to effect the result other than the force of the mechanism employed, see Busch v. Jones, 990, g. 205. If the answer is no, there is no such process. If the answer is yes, then there is a process.

In these claims there are two forces which are not those of the apparatus merely; first, the force of a necessary body of water operating on a gaseous body to compress it, and second an expanding force of those gases when expanded, operating on that forcing body of water. Here are two forces co-operating, neither of them the force of the mechanism, to perform the useful result of the procedure, and these two non-mechanical forces operate on each other. It follows that the claims express an art in the meaning of the Statute.

APPENDIX II.

A United States patent was applied for for an evaporating apparatus, in which a series of upright walls of serpentine tubes, heated internally by steam, were placed side by side, and between each two walls were placed upright corrugated plates, the liquid to be evaporated being made to flow down both the tube walls and the plates, that flowing down the latter being evaporated by the heat radiated from the tubes. Previously, such apparatus had been constructed with the tube walls only, and by substituting for every intermediate tube wall a single plate, the cost of the apparatus and consumption of steam was considerably reduced, while the evaporative effect

* The first ground of rejection was an alleged anticipation by a prior patent which was also ruled to be erroneous by the Examiners-in-Chief.

obtained was shown to be practically the same in both cases. The United States examiner found that an evaporating apparatus had been previously patented, in which only upright plates had been used for the liquid to flow down, the evaporation thereof being effected by means of currents of hot air passed between the plates. In consequence hereof he refused the above application on the ground that there was no patentable invention in substituting for the alternate pipe walls of the one known construction the plates of the other known construction.

On appeal to the Examiners-in-Chief they reversed the decision of the examiner, with the following statement:—

"We are unable to ascertain that either of the references discloses vertical plates intervening between and near to vertical walls of pipes, and a feed for the liquid leading to both pipes and plates. We understand that the statement of the examiner admits this novelty, his contention being that the new construction is not a new invention.

"To this conclusion we cannot agree. Inventors have been continuously striving to obtain greater range of distribution of the liquid relatively to a coil of pipes carrying the heating medium. This arrangement gives a greater liquid evaporating surface for the contact of the air currents than any other arrangement of pipes affords; it is, therefore, an improvement in such structures. An improved result of a kind which is material in the art, affords a presumption of more than the effort of ordinary mechanical knowledge and experience. There is nothing in the record to overcome this presumption."

APPENDIX III.

A German patent was applied for in respect of an invention connected with ice-making machinery. The invention related to the compressor cylinder, one improvement relating to the cylinder itself, and another to the valves of the cylinder.

The examiner insisted that these were two independent inventions requiring two separate patents, and after long arguments on the point, the inventors complied with the examiner's request, and filed a separate application for the valve construction, limiting the original application to the cylinder construction. Now both inventions had a common feature, namely, that the higher temperature of the incoming vapours was utilised for warming these parts of the apparatus through which the colder outgoing vapours had passed, and thus preventing an accumulation of rime in the passages. Unfortunately in dividing the applications, a claim was added in the one for the cylinder construction in which this interchange of temperature was referred to and a similar reference to such interchange was also made in the original claim for the valve construction.

The examiner, in looking at the amended specification of the original application, saw these words in the claim in question, and without taking the trouble to read the claim through jumped to the conclusion that the inventors were still claiming in this patent the construction of the valves, and he thereupon without further ado refused the application on the ground of non-compliance with the request for the separation of the valve invention from that relating to the cylinder. The inventors were thus put to the considerable expense of appealing against the examiner's decision, owing to his carelessness in not properly reading this specification. The following further absurdity occurred in this case. As before stated, the inventors in compliance with the examiner's decision, lodged a separate application for the valve construction; for the proper understanding of this invention, it was necessary to show in the drawings the complete compressor cylinder, which, of course, also showed the above mentioned improvements in that construction; but, naturally, as according to the examiner's decision that the latter had nothing to do with the valve construction, the description of it was entirely omitted.

The examiner having considered this new application, was good enough to say that the subject-matter appeared to be patentable, but before passing the application he would require some description of the new cylinder and piston construction, to be inserted, as he considered it necessary that some explanation should be given in that respect. He thus contradicted his own previous decision that the two parts of the invention had no relation to each other.

APPENDIX IV.

Supreme Courts of the United States. United States *ex. rel.* Steinmetz *v.* Allen, Commissioner of Patents. Decided February 23, 1904. Abstract of the Judgment of the Court. Statement of the Case.

This is a petition in mandamus filed in the Supreme Court of the District of Columbia to compel the Commissioner of Patents to require the Primary Examiner to forward an appeal, prayed by the petitioner, to the Board of Examiners-in-Chief, to review the ruling of the Primary Examiner requiring petitioner to cancel certain of his claims in his application for motor-meters.

The Supreme Court dismissed the petition, and its action was affirmed by the Court of Appeals.

The writ of error was then sued out.

The decision of the Primary Examiner was based upon Rule 41 of practice in the Patent Office, and the case involves the validity of the rule under the Patent Laws. The petitioner filed an application in the Patent Office, November 21, 1896, for a patent for "certain new and useful improvements in motor-meters." He expressed his invention in thirteen claims. The first six were held by the Primary Examiner to be claims for a process, the balance of the claims to be for an apparatus; and on the 15th

May, 1900, ordered that the latter—that is, claims, 7, 8, 9, 10, 11, 12 and 13, be cancelled from the application.

In other words, he required a division between the process claims and the apparatus claims in accordance with Rule 41. That rule is as follows:—

41. Two or more independent inventions cannot be claimed in one application; but where several distinct inventions are dependent upon each other and mutually contribute to produce a single result, they may be claimed in one application.

Claims for a machine and its product must be presented in separate applications.

Claims for a machine and the process in the performance of which the machine is used must be presented in separate applications.

Claims for a process and its product may be presented in the same application.

Petitioner persisted in his application as filed, and the Primary Examiner repeated his order for a division of the claims. Petitioner regarded such order as "a second final rejection" of his claims to the apparatus, and appealed therefrom to the Board of Examiners-in-Chief. The Primary Examiner refused to answer the appeal and to forward the same with his answer thereto, and the statements required by the rules of the Patent Office.

Thereafter, on the 20th August, 1900, petitioner petitioned the Commissioner of Patents to direct the Primary Examiner to forward said appeal, which petition was denied. It was repeated to the present Commissioner, defendant in error, and by him denied on the 7th February, 1902. These facts constitute petitioner's claim to relief.

* * * * *

Mr. Justice McKenna, after stating the case as above, delivered the opinion of the Court.

After deciding upon the question of the jurisdiction of the Court, he said:—

"The issue is well defined between the parties, both as to the right and remedy, in the Patent Office. As to right, the petitioner contends that a union by an inventor of process and apparatus claims, which are essentially the same invention, is given by the Patent Laws, and that Rule 41, so far as it takes that right away, is repugnant to those laws and invalid. As to remedy, that the decision of the Primary Examiner constituted a final decision upon the case, and petitioner was entitled to an appeal under Patent Laws to the Board of Examiners-in-Chief. The latter proposition depends upon the first.

Assuming the right in an inventor as expressed in the first proposition, the Primary Examiner denied the right. True, a distinction can be made between his ruling and one on the merits, if we regard the merits to mean invention, novelty, or the like. But in what situation would an applicant for a patent be? If he does not yield he will not be heard at all, and may subsequently be regarded as having abandoned his application (see 4894, R.S.) A ruling having such effect must be considered as final and appealable.

Whether, however, to the Examiners-in-Chief or to the Commissioner, and from the latter to the Courts, we may postpone answering until we have considered the right of an inventor to join process and apparatus claims in one application.

There is nothing in the language of the Section 4886 of the Revised Statutes which necessarily precludes the joinder of two or more inventions in the same application. But the section does distinguish inventions into arts (processes), machines, manufactures, and compositions of matter, and the earliest construction of the law denied the right of joinder. An exception, however, came to be made in cases of dependent and related inventions. The decision would seem to imply that not the statute but the practice of the Patent Office required separate applications for inventions, but the cases cited were explicit of the meaning of the Statute.

Can it be said that a process and an apparatus are inevitably so independent as never to be "connected in their design and operation?" They may be completely independent (Cochrane *v.* Deener, 94 U.S. 780), but they may be related. They may approach each other so nearly that it will be difficult to distinguish the process from the function of the apparatus.

* * * * *

The Patent Office has not been consistent in its views with regard to the division of inventions; at times convenience of administration has seemed to be of greatest concern; at other times more anxiety has been shown for the rights of inventors.

The policy of the office has been denominated that of "battledore and shuttlecock" and Rule 41, as it now exists, was enacted to give simplicity and uniformity to the practice of the office. Its enactment was attempted to be justified by the assumption that the Patent Laws gave to the office a discretion to permit or deny a joinder of inventions.

But, as we have already said, to established a rule applicable to all cases is not to exercise discretion.

Such a rule ignores the differences which invoke discretion, and which can alone justify its exercise, and we are of opinion, therefore, that Rule 41 is an invalid regulation. Having settled the right of appellant, we may now return to the consideration of his remedy.

* * * * *

The Commissioner justifies his decision by the rules of the Patent Office, and a long practice under them. If there is inconsistency between the rules and statute, the latter must prevail. But the Primary Examiner did not follow the rules.

The rules provide that if an appeal be regular in form he shall within five days of the filing thereof furnish the Examiners-in-Chief with a written statement of the grounds of his decision on all points involved in the appeal, with copies of the rejected claims and with the references applicable thereto.

If he decide that the appeal is not regular in form, a petition from such decision may be made directly to the Commissioner. The regularity of the appeal in form is not questioned in the case at bar, and it was the duty of the examiner to answer the appeal by furnishing the Examiners-in-Chief, the statement provided for in Rule 135. A petition to the Commissioner was not necessary except to make the examiner to perform his duty.

The judgment of the Court of Appeals is therefore reversed, with directions to reverse that of the Supreme Court to grant the writ of mandamus as prayed for.

NOTE.—It is of interest to observe from the above, that it took the inventor, Steinmetz, over seven years (from 21st November, 1896, date of his application, to 23rd February, 1904, date of judgment) to establish his rights as against an improper rule of the Patent Office, and the improper action of the examiner.

DISCUSSION.

The CHAIRMAN, in opening the discussion, said it could not be denied that the question of how the patent laws ought to be framed for the benefit of the proper parties was a very difficult one, and the mere fact that in all countries the way of carrying out the patent laws was different, showed that there was still an uncertainty as to what was the right way to frame them. With the two first conclusions of the author he was absolutely in agreement, but he would go a little further and say that all official examinations of patents were an evil. The author did not say that the proposed system of examination of English patents had exactly the same faults as the German and United States examinations had. The remedy lay, in his opinion, in making the inventor search for himself. It was a curious thing that the author in 1865 stated exactly what was the right thing, viz., that the Patent Office should be made a technical guide and purveyor of useful knowledge to the inventor and to the public generally; then if anybody had an idea which he thought might be made into a patent, instead of going and filing a description of the idea, he ought to be able to go to the Patent Office and say to one of the officials, "I have got an idea for a new set of bearings; will you please direct me to that part of the office where information can be obtained about bearings," and then the inventor could sit down and study the subject. The inventor himself knew perfectly well what his invention was, and what advantages attached to it, and he could read all prior applications for patents for bearings with a totally different mind to that of an official examiner. The author had given instances, which occurred every day, where the examiner did not understand the invention or had not troubled to make himself perfectly acquainted with it, and had stated that an enormous staff of examiners was required to deal adequately with the question. The staff of the Patent Office should be employed in registering all information that came in, and he thought the idea of a roving commission was an extremely good way of collecting information. The information should be indexed and analysed as much as possible, so that when an inventor came for certain information he could get it quickly. His objection on the subject was that the original Statute of Monopolies did not say that the inventor should be the person who benefited; the statute said "The privilege shall be granted of the sole working and making." It referred to the privilege of working and making, and not to inventing, and that was the object of the law. It would be seen also that "Communications from abroad" were placed on exactly the same footing as original inventions. It was not the man who suggested a new idea who ought to be rewarded, but the man who introduced it; but it must not be forgotten that in most cases he was one and the same person. For instance, the names of Bessemer and Siemens were mentioned in the paper; they were inventors certainly, but they also introduced their inventions, and it was not for the inventing that they got their reward, but for the introducing, and that was really the point on which the whole patent legislation of the present time in all countries went wrong. It was easy to invent, there was nothing in that, but it was extremely difficult to introduce a new manufacture, and the people who did introduce new manufactures ought to be the people who were rewarded. If the judgments in important patent cases were read, it would be found that the Judges were of exactly that opinion, and it was also in conformity with the principle that the real proof of the value of an invention was its adoption. If an invention was not worth adopting it was not worthy of reward. It was a common mistake to say that there were lots of inventors who went about but could not get a manufacturer to adopt their invention, and that therefore good inventions went begging and the public lost. That appeared to be so, and the inventor who said that was no doubt perfectly honest. For instance, if an inventor came to him with an electrical invention it was ten to one that he (the Chairman) knew more about it than the inventor did. If it was a thing on which his firm had made experiments a few years previously, and knew that it was commercially impracticable, he said to the inventor that he was very sorry he could not make use of the invention, but if he gave reasons, the inventor would begin to argue, and, as Sir William Siemens used to say, when an inventor came to him, he knew he would lose two hours of his valuable time, and would make an enemy for life. It was a mistake of the patent laws of all countries to try to reward an inventor simply because he had made an invention. That was not enough; he ought to introduce it, because by its introduction he proved that it was valuable. There was no other proof, and if the man succeeded in introducing it, then the law ought to go further, and grant him

a real monopoly. The author had instanced a case in which it took an inventor seven years to induce the United States Patent Office to allow an appeal, and even then his patent was worth nothing until he had fought a law suit. Under the present patent laws, in any country a real patent was not obtained until it had been fought through a court, but, in his opinion, when an invention was introduced commercially, a patent should be granted to it which could not be upset, and thereby the introducer of the invention would get a real benefit.

The SECRETARY read the following letter from Sir Lloyd Wise:—Being under engagement to preside at a large gathering this evening, I am, unfortunately, not in a position to avail myself of the courteous invitation of the Council to attend to-day's meeting of your Society. This I regret the more because, having co-operated for nearly thirty-five years with my friend and professional colleague, Mr. C. D. Abel, in the promotion of patent law reforms, I should have been peculiarly interested in hearing his paper read.

I, of course, do not know that particular branch of the subject he will deal with, much less the views to which he may give expression. But, in the interest of inventors, I desire, if in order, to direct special attention to the new patent rules, which seem to me highly objectionable.

In my opinion they point to about the most obnoxious method that could possibly have been devised of carrying out the provisions of Section 1 of the Patents Act of 1902. This is the more unfortunate because effect might readily be given to those provisions in a manner that would prove advantageous both to inventors and the public.

I suggest, in particular, that the utmost possible pressure should be promptly brought to bear with the view of getting the rules so far modified that in carrying out Section 1 of the Patents Act, 1902, the special forms of reference to prior patents set out in Rule 10 of the Patents Rules, 1905, shall apply only in cases where the applicant has not already mentioned the prior patent in his specification, and has been duly notified of the Comptroller's determination that a reference to a prior specification ought to be made, and has failed to embody in his own specification, in his own way and within a specified reasonable time, a reference by number, year, and name to such prior specification.

As I see that Mr. Alexander Siemens is to preside, I can, perhaps, best illustrate my meaning by referring, by way of example, to one of his firm's own patents, in obtaining which Mr. Abel's firm acted professionally. It is No. 6220 of the year 1899, and in the complete specification there is given an outline of the state of the art, and a prior specification of Jablochkoff's, No. 1996 of 1877, is specifically mentioned.

That is one example of the sort of unobjectionable reference I contemplated when giving evidence before the Departmental Committee in 1900. But according to the new Rule 10, if the applicant once goes the length of troubling the Comptroller to determine whether reference ought to be made in the applicant's specification to any, and if so, what, prior specification or specifications by way of notice to the public; then, should the Comptroller's decision be affirmative, an official notice is to be placed upon the unfortunate applicant's specification in these terms:—

"Reference has been directed, in pursuance of Section 1, Sub-Section 6, of the Patents' Act, 1902, to the following specification of Letters Patent, No. ....granted to......................."

Where the reference is inserted as the result of a provisional report, under Rule 7, a statement to that effect is to be added to the reference.

Surely an applicant should be allowed to take a patent at his own risk, provided he (himself) specifically mentions the prior patent or patents, reference to which is regarded as necessary for the protection of the public. The mention thereof by No., year, and name, would obviously be a notice to the public, inasmuch as his specification is addressed to the public. Why, then, should it be in any way made known, to his prejudice, that he referred to the prior patent under compulsion? The contemplated practice will be tantamount to publication of an official report to the effect that, in the opinion of the Comptroller, the patent is invalid.

What justification can there be for thus handicapping inventors whom the patent laws are intended to encourage? Why not give the patentee absolutely fair play?

If the framers of the Act had contemplated the sort of practice seemingly intended to be set up, surely they would not have expressly prohibited, as they did in the Act, publication of reports of examiners, which, as a matter of fact, formed an essential part of the original scheme as approved by the Society of Arts, after full discussion, in 1877, and submitted by me, as the Society's delegate, to the International Congress at Paris in 1878.

In conclusion, I may mention that the whole subject is pretty fully dealt with in a leading article which appeared in *Engineering* of Friday last, 9th inst.

Mr. P. M. JUSTICE said he was in thorough accord with the bulk of the author's suggestions. He thought that if an examination was to be made, as it was now settled it was to be made from the 1st of January next, it should be as complete as possible. But, in his opinion, Mr. Abel had omitted one of the essential features of the examination, viz., the fact that the examination would in no way determine the validity or non-validity of the patent. Those who were familiar with patents knew that it was just as easy to anticipate a British patent, by the publication of the German specification or the American specification, so long as it was sufficient, as by an English specification. The examination in this country was to be limited simply to British specifications, not to British

or foreign publications, and he thought Mr. Abel might with advantage have pointed that out in his paper. He agreed thoroughly with the author that the examining staff should be increased. Apparently they did not have to work for so many hours as the poor German examiner, who topped the list. He had been told by the German examiners that they found it a physical impossibility to get through the examination of their cases in office hours, and that three nights in the week they took their papers home to work upon them. He did not think that ought to obtain in this country, and he hoped the examiners would not be overworked; at any rate he felt perfectly certain that we ought to have the best examination the examiners were capable of giving. He also believed there was going to be a very fair subdivision of inventions. Many present were aware of the Chairman's strong opinion, that it was the man who produced or worked the invention who should be rewarded, but he (Mr. Justice) ventured to say that the Chairman's firm had several hundred patents on their books, which were either in existence or which they had allowed to lapse, which they had never really worked as patents, and he would like to ask whether the Crown or the public was deprived of anything by the granting of those patents. If an inventor went to the Patent Office, and his patent was valid, he obtained a monopoly for fourteen years; if the invention was no good he did not work it, or get anybody else to work it, but no one was harmed thereby. He thought the Chairman might well cry quits to such an inventor. He agreed that where a man was successful in introducing an invention, he should be remunerated, if possible, and he saw no practical means of his securing such remuneration except by the grant of a patent.

Mr. G. G. HARDINGHAM thought the Legislature had scarcely appreciated the fact that inventions were peculiar things to deal with, which changed from day to day. The English system was based, to a large extent, upon the assumption that an invention was something of a definite character. So far as his experience went, it was of an indefinite character, and that was where a great many troubles arose, particularly in connection with the Provisional Specification system. It was very difficult to see how the system which was to be brought into operation in January next could be worked satisfactorily with the prevailing system of initiating applications on provisional specifications. It was true that the examination was to be made upon the complete specification, but inasmuch as complete specifications had necessarily to be founded upon provisional specifications, he thought very considerable difficulties would arise; and he hoped the system would be modified to the extent of abolition, because it was a thoroughly bad system. If a man was entitled to go to the State and ask for a patent, he should be able to define the invention for which that patent was sought, and he was not entitled to a grant which he could put in force against the public until he had defined the invention. Inasmuch as English patents were dated back to the date of the application, which, in the majority of cases, was that of the provisional specification, it would be seen that the patent was really granted upon something which was of an indefinite character, because it was founded upon the provisional specification. The difficulty turned upon the question of date, because patents were dated back in that way. If patents were dated from the date of the complete specification he would have no objection whatever, but until that inherent difficulty was abolished, he was afraid a satisfactory system would not be obtained. He had noticed, as Mr. Justice had pointed out, that the author had made no reference to the fact that the proposed examination was of a quite incomplete character. It seemed to him perfectly futile to examine merely a small branch of publications. A patent might be upset in this country upon the ground of prior publication, which might be found in the specification of a British patent within the last fifty years, or in the specification of a United States, German, French, or any other specification or publication, and to introduce a system of examination of that extremely partial character would be simply useless, and very misleading. English patents would be upset quite as often, as they were at the present day, on the specifications of United States patents as on the specifications of British patents. He entirely failed to see why, if there was to be an examination at all, it should not be the very best kind of examination procurable. If the United States and the German examiners could examine other specifications than their own, surely the British could.

Mr. OSCAR GUTTMAN thought the new system ought to be given a chance, but he was afraid the new examination would not be of much use. He agreed with Mr. Hardingham that an examination based upon British patents which only went back fifty years was, especially in the chemical industry, quite useless, and would exclude a very large source of information with regard to prior inventions contained in English and foreign literature. In a good many cases with which he was acquainted the search in foreign literature had been so fruitful of anticipations, in law cases and otherwise, that to limit the search in the way proposed was quite ridiculous. Another objection was with regard to the quality of the examiners. He happened to know the quality of the junior examiners in Germany, and also knew the standard for the assistant examiners who were selected in this country for positions under the new patent law. He was afraid the Germans would come out better in that respect, but he did not wish to discourage the young men who would be assistant examiners; probably in a year or two they would have greater experience than they at present possessed. In Germany an assistant examiner must have been at some works and had some practical experience, or he must have undergone a course

of very severe study. In this country assistant examiners were chosen, not according to the record of their study or work, but by means of the wonderful competitive examinations which existed in England, where generally not the clever men were at the top but those who went through an examination best, and it was well known what a curse the examination system had been in this country in all sorts of professions. The author had referred to a lecture he gave before the Society of Engineers, in which it was stated that the examiner should not have power to refuse any patent, except when it referred to some nonsensical matter. He did not think even that power should be given to an examiner. He knew of a case where the patentee applied to the German Patent Office, and an eminent professor told him that although the German Imperial Patent Office might grant a patent on an invention which might not prove useful, it was not the object of the Patent Office to grant a patent for nonsense, and that that patent was nonsense. The inventor thereupon requested the Patent Office to send a Commission to his works, and proved, to the astonishment of the Commission, that it was not nonsense and that it worked, and, strange to say, the famous Professor, who had given the previous opinion, later on wrote a book on the usefulness of the invention. He believed a great dea of harm was done by the system of examination in Germany, inasmuch as it was possible for an examiner to throw every obstacle in the inventor's way. The author had mentioned a case where a patent was delayed for seven years in America, and he (the speaker) was now investigating a patent which had been delayed for four years in Germany. The poor inventor, therefore, only had six or seven years left in which to develop his invention and make it useful, and this was very unfair to him. On the other hand, it was quite impossible that the inventor himself should search in the way suggested by the Chairman. The inventor was, in most cases, a child; he was so infatuated with his invention that he would not listen to reason. Whatever he read, he would find an argument in his own favour, and there must be somebody, either an expert outside or an expert in authority, who would tell him that he was wrong. There was another way of dealing with the question, namely, to give the public generally a right to object to a patent, which was the system prevailing in Germany, but the English patent law had set its face against that proceeding, and would continue to do so. Nobody in this country could oppose a patent unless he had a prior patent himself, which on some grounds or other was similar to the new one. If the outside public were allowed to search, and as a result of their search to oppose a patent, and a reference was then made, he thought the search would be useful, but not otherwise.

Mr. WALTER F. REID wished to express his agreement with most of the points raised in the paper, especially that which related to the searches which took place in Germany and the United States. If the searches were carried out in England in the same way as in the United States, they could only be an evil. The objections raised in the United States Patent Office were sometimes of a most stupid character; anything that bore in the most distant way on the invention was sent to the poor inventor to find a reason why it did not anticipate his patent. He hoped the English Patent Office was not beginning a state of affairs which at all resembled the procedure in America. He thought the figures given in the Table of the number of hours spent by the officials in searching were not altogether comparable. It must be borne in mind that the search which the English officials would have to carry out would be a very limited one; therefore, possibly the number of hours and the method they employed would be quite sufficient to do the work fairly, because, as he understood it, they would have only to investigate prior specifications in this country for 50 years, not the whole of the literature, as was done in Germany and the United States. He wished to dissent from the Chairman's remarks with regard to the introducer and the inventor. It might not always be quite so easy as it appeared to invent a thing, because it pre-supposed a very considerable study of the subject before one was in a position to invent; and it must also be remembered that some of the greatest inventors had been outside the particular business which was engaged in working the subject matter of the invention, Bessemer being a notable example. The quotation which the Chairman made was also rather antiquated. That was the view held some hundreds of years ago, but the present view was totally opposite. For instance, the patent for the Parsons turbine was prolonged simply because it had not been introduced, which he thought was fair, because an inventor might have spent a great deal of time in inventing his article, and yet it might not be introduced commercially, although it was a good invention. Therefore he thought the present view was much fairer than the old view which the Chairman had mentioned.

The CHAIRMAN, in proposing a hearty vote of thanks to Mr. Abel, which he requested Mr. Bloxam to convey to that gentleman, said he did not desire to alter the way in which English patents were granted at the present time; he only desired that when the patent was introduced it should then automatically become a real monopoly, without a law suit.

The resolution was then put and carried unanimously.

Mr. BLOXAM, in replying on behalf of Mr. Abel, thanked the audience for the kind vote of thanks which had been passed. He did not know that he could venture to undertake to express Mr. Abel's opinions in reply to the points which had been raised in the discussion, but he thought Mr. Abel would be disposed to say to the Chairman that in patent

matters more than in anything else the old adage, "So many men, so many opinions," applied. With regard to the inventor searching for himself, when an inventor came to a patent agent, the first question he was asked was whether his invention was new, and the prompt reply was given that it was, and that he had spent so many days at the Patent Office searching, and could not find a single anticipation. The patent agent then produced his volume of abridgements, and turned up the anticipation at once. The inventor was very seldom sufficiently well informed in the art of searching, because it was a very considerable art to be able to discover anticipations of inventions. The remarks made by other speakers were very much to the point, and he could only thank them for having taken part in the discussion.

COUNTY COUNCIL SCHOLARSHIPS.

The scholarship systems both of the School Board and the London County Council have stood the test of time. At the end of the last financial year the total number of scholars and exhibitioners holding awards under the Council was 3,174. During last year there were 3,416 candidates for the Junior County Scholarships, 952 for the Intermediate, and 100 for the Senior. The county scholarship system has formed a ladder to carry on the junior scholars from the public elementary schools, and that the Council has been enabled to secure able candidates for its scholarships is shown by the fact that during last year alone no fewer than eleven of the Council's scholars obtained scholarships in the universities, or institutions of university rank. Many senior county scholars obtained degrees in honours, while in 1902 the Senior Wrangler was a London County scholar who had received his early education in a public elementary school. On the more technical side one scholar has recently been appointed a probationary constructor to the Admiralty. Many have been awarded research scholarships in science by the Royal Commissioners of the 1851 Exhibition; several of the Council's senior county scholars have assisted in the conduct of important research work; many of the Council's intermediate scholars have obtained good appointments in engineering works; and there are many instances of artisans improving their positions through the aid of the courses which they have pursued as evening exhibitioners in science or technology. But one of the results of the Education Acts of 1902 and 1903 is to compel a complete recasting of the scholarship system which the Council, through its Technical Education Board, has administered since 1893.

The Education Committee have now submitted to the Council a very bold and almost revolutionary scheme. The existing educational ladder from the board school to the universities is to be greatly enlarged. It is proposed that the present 600 scholarships shall be increased to 3,000, at a cost, when the new scheme is in full operation at the end of five years, of £275,200. The committee propose to abolish all examinations except the elementary test in arithmetic and English composition, or, to quote their own words, "Simple common-sense problems in arithmetic (including alternative questions so as to deal evenly with all candidates) and an exercise in English composition calculated to test not only handwriting and spelling, but more particularly intelligence and powers of observation and expression." The committee say that the objects of this choice and limitations of subjects are (*a*) to supply the indispensable element of comparison among the candidates from the whole of London without encouraging special preparation; (*b*) to enable the examiners to judge intelligence rather than mere memory work, and (*c*) to leave open to candidates of varied tastes a way of displaying that intelligence. It was urged upon the committee that the system of selecting the ablest children from London as a whole results unfairly to the children in the poorer districts, and that a proportionate quota of scholarships should be allotted to each district. The committee dissent from this view. Experience shows, they say, that the winners of the Council's scholarships during the past eleven years have come from every part of London, poor as well as rich. "A considerable number of these scholarships have been won by children coming from extremely poor homes, the sons and daughters of dock and other labourers, porters, carmen, charwomen, needlewomen, &c. Though the proportion per district of scholarships to the children in public elementary schools has varied in particular examinations from 0 per 1,000 to 2·7 per 1,000, this variation by no means corresponds to the poverty of the constituency, the districts standing lowest on the list being Paddington (South), Westminster, the Strand, and the City, as well as Finsbury (East), St. George's-in-the-East, and Holborn; whilst relatively poor neighbourhoods such as Rotherhithe, Hackney (Central), Deptford, and Finsbury (Central), have secured high places." The committee feel that to allocate a definite number of scholarships to each district must necessarily diminish the keenness of the competition, lower the general average of quality, and result in the exclusion of able children in some districts by less able candidates from other districts. The local distribution of scholarships seems rather to depend upon the character of the schools, and the amount of attention paid to the matter, than the relative poverty of the district. Moreover, even within each district there are poor streets and relatively rich ones, highly efficient schools and schools working under less favourable conditions, so that, in the opinion of the committee, the allocation of a fixed grade to a district would fail to secure scholarships to the poorer streets and the weaker schools.

Hitherto only children whose parents were earning not more than £3 a week have been eligible for junior county scholarships. The committee propose that

any child who has attended any elementary school for two years may become a scholarship holder. In the opinion of the committee, the restriction of the competition to the children of parents below a certain income is invidious. It lowers the average standard of quality by excluding some able children whose parents may not really be in better circumstances than others below the limit. To quote from the Report, "The Council's scholarships should be, it is said, not badges of poverty but titles of honour. Moreover, it is desirable, on many grounds, that a mixture of social classes in the public elementary schools should be encouraged. Especially is it important that the present growing tendency of middle-class girls to enter the teaching profession should not be discouraged, and that the way should be left open for the future pupil teachers to be drawn from all social classes. On the other hand, we feel very strongly that it is only by the firm retention of an income limit, at any rate, as regards the payment of maintenance, that access to the scholarship ladder can be made really effective to the clever childen of the poorest homes." The junior county scholarships will, as we have said, be open to all children living within the administrative county, who have been for at least two years attending an elementary school, and with regard to a money payment (maintenance allowance) in addition to free education, the committee recommend that it should be dissociated from the widely published scholarship award and granted separately by the Council only to those scholars who require it. By this separation, the Committee think the Council can combine "the very great advantage of making its junior county scholarships titles of honour without being badges of poverty, whilst continuing to confine its maintenance grants to those who need them. It would no longer be possible to identify a junior county scholar as necessarily coming from a poor home."

A scheme so wide in its scope, and so costly to the ratepayers—in addition to the £275,200, there must be a heavy outlay for more secondary schools—is certain to be hotly discussed. The objections most likely to be urged may be summarised as follows:—(a) The drafting of 3,000 children every year into the secondary schools. (b) The abolition of all examinations, except an elementary test in arithmetic and English composition. (c) The hostility shown to special scholarship classes. (d) The selection of twice as many girls as boys. (e) The restrictions on the continuance of the scholarships after 14, unless a bond to become teachers is entered into. (f) The injustice to some of the poorest scholarship holders in depriving them of advantages to which they are justly entitled, by reason of their parents' inability to enter into a bond that their children (then 14) shall become teachers at 16, and enter a training college at 20. The last three criticisms are urged in a memorandum to the committee presented by the London Teachers' Association, which considers that "the great blot in the whole scheme appears to be the desire to secure candidates for the teaching profession, rather than to improve the general education of the children."

*TECHNICAL EDUCATION IN INDIA.**

When India passed under the rule of the Crown, the Government found a more or less widespread, but very rudimentary, system of education in vogue. There were Hindu village schools, generally of a secular character, and Muhammadan schools primarily devoted to religious instruction. From an early date also the missionary societies have played a prominent part, both in educating the low castes, aboriginal races and female populations, and in maintaining institutions attended by the more advanced sections of the population. Of the primary and general education mention need not be here made. On the other hand the scope of the professional and technical training afforded is so vast and of such importance to the welfare of our Indian Empire generally as to merit a brief review. The principal subjects are law, medicine, engineering and surveying, agriculture, veterinary science, forestry, commerce, art, and industry. Law is taught mainly in the Government law colleges, situated in the capitals of the various provinces. Medicine is taught in two grades, the upper at four large Government colleges, and the lower at eleven Goverment schools. The colleges train students for the assistant-surgeon class for employment in State hospitals and dispensaries, the schools training students for a lower or hospital assistant class.

The work of the engineering colleges at Rurki, Sibpore, Poona, and Madras in preparing subordinate officers for the P.W.D. is well-known. Sibpore and Poona, have, however, an agricultural side, while other institutions such as the College at Saidapet, and special schools at Cawnpore and Nagpur are purely devoted to agriculture. The various colleges and schools devoted to veterinary science, together with the Imperial Forest School, train their students mainly for positions in Government employ.

The writer of the report does not regard the present condition of commercial teaching with much favour. There is very little of an advanced character. A number of schools teach shorthand and type-writing, and a smaller number give more or less elementary instruction in book-keeping, correspondence, commercial geography and kindred subjects.

There are four schools of art under Government control. Their special function being to restore, develop, and improve the application of oriental art to industry and manufacture. Of these schools that at Madras, on its industrial side, deals with the manufacture of bricks, tiles, pottery, water-pipes, smith's work, &c. The connection between decorative art and this department is therefore very slight. On the

* "Progress of Education in India." Fourth Quinquennial Review, Cd. 2181, 2 vols. Published by Eyre and Spottiswoode. (1904.)

technical side, drawing, painting, modelling, wood engraving, and copper-plate engraving are taught. This school does not seem to be in a very flourishing condition. The number of students has fallen steadily from 633 on March 31st, 1897, to 321 on the same day in 1902. Higher fees, and a rule requiring unpaid apprentices to pay class fees for attending drawing classes, are ascribed as partial causes of the decline. Further, the Government technical examinations held in 1901 were not very favourable to the school.

The Bombay School of Art dates back to 1857. At present (in addition to the Reay art workshops opened in 1891) the institution comprises a drawing school, modelling and painting classes, together with drawing teacher's course, and an architecture and draughtsman's class. The trained pupils find ready employment, its students having executed much of the decorative work which adorns the city of Bombay. In the art workshops house painting and decoration, enamelling, gold and silver work, carpet weaving, copper, brass, and iron work, wood-carving and pottery are each taught. The number of students, which fell on account of the plague, has since increased greatly, and the institution is both flourishing and improving.

The Calcutta School of Art, on account of the sparsity of indigenous art in Bengal, has no manufacturing industrial side. Systematic instruction is given in drawing and design, for teachers, draughtsmen, artisans, and art designers. Wood engraving, lithography and modelling are taught. The number of pupils has fallen slightly during the quinquennial period under review.

The Mayo School of Art at Lahore gives instruction in the arts of design, with special reference to the indigenous industries of the Punjaub. The majority of the pupils—whose numbers are increasing—are of the artisan and trading classes. Some of its pupils have been employed as designers in the Punjaub carpet factory. Of the twenty-eight pupils who left in 1901-02, all but two have obtained suitable employment ,none, however, appearing to follow the indigenous handicrafts, which it is the special province of the school to encourage and foster.

Space does not avail for the treatment, even in abstract, of the various industrial schools, of the Government, local board, reformatory or "aided mission" types. Generally speaking, these have not been very successful. In many cases, it has been necessary to attract pupils by means of stipends, the stipend-holders, being often boys of the non-industrial classes, who attend merely for the sake of the literary instruction which is combined with the industrial training. To those who consider Blue-books dull or tedious, this quinquennial report may well be commended. It is likely to interest even those who do not study educational systems. To those, however, who are interested in education, primary or secondary, this record of progress will be almost invaluable, as treating of problems which confront no other governing race in the world.

THE SHANGHAI RIVER CONSERVANCY

The following information respecting the important question of the improvement of the Shanghai River Navigation (*see ante*, vol. lii. 860), is from *The Times* correspondent at Shanghai, dated December 2nd:—

Sir William Bredon, Deputy Inspector-General of Customs, goes to Pekin to-morrow. He intends to submit for the consideration of the Wai-wu-pu and the Diplomatic Body certain proposals, approved by the Nanking Viceroy, Chou-fu, for a scheme with reference to the Shanghai River Conservancy, to be embodied in a new convention to take the place of Annex 17 of the Peking Protocol. The scheme follows generally the lines of the recent despatch of Sir Ernest Satow to the Wai-wu-pu accepting the principle which was originally enunciated by the Viceroy Liu Ku-nyi, that China should carry out the work at her own charges under the supervision of the Maritime Customs, giving guarantees for its due performance.

With regard to the nature of the guarantees the Viceroy was unable to accept Sir E. Satow's conditions, which are stringent, but he expressed a desire to begin the undertaking forthwith and stated that there could be no difficulty as to funds being regularly forthcoming in advance. A memorandum setting forth the proposals is now under consideration by the Chamber of Commerce and the Municipal Council, and it is probable that these and other local bodies will support them. It is evidently desirable that the Diplomatic Body should seize the occasion of the new progressive Viceroy's appointment in Nanking to supersede the unworkable Protocol by a practical solution of this important question.

The Viceroy, Chou-fu, during his stay in Shanghai has created a universally favourable impression. His appointment to Nanking is timely because his influence is calculated to counteract the policy of Chang Chih-tung at Wu-chang, which since 1901 has steadily become more reactionary and ill-advised.

CORRESPONDENCE.

THE BRITISH CANALS PROBLEM.

As I understand Mr. W. D. McConnell, he admits:—

1. That the utility of our waterways may be largely increased.

2. That some remedy for the existing condition of the waterways should be found.

But he argues:—

1. That if private owners have a fair field for their enterprise they will not hesitate to incur expenditure in the improvement of their property.

2. That it would be a disastrous policy to give power to local authorities to add to their burden of debt.

3. That it is doubtful if sufficient data can be given to show even a probability of a sufficient increase of canal traffic to justify such a course.

In reply I contend :—

1. That it is impossible for private owners of canals to get a fair field for their enterprise so long as it is the deliberate policy of railway companies to crush canal traffic by carrying to competing points under cost, making up the loss thus sustained by increased charges to places where effective competition by water has been destroyed or does not exist.

2. That the cost of transport to inland towns of imported goods of universal consumption falls on the community as a whole.

3. That capital subscribed from private sources and expended on developing a waterway so as to reduce the cost of transport may be deprived of all return by a consequent reduction in railway freights. In this case all pecuniary benefit being reaped by a local community (*a*) at the expense of the private capitalists aforesaid; (*b*) at the expense of other localities who may have to pay higher railway rate to make good the loss sustained at the competitive point.

4. That to point to an increase of debts without considering any increase in the value of assets is not reasonable. It may, for example, be contended that the railway companies increased their burden of debt from £560,000,000 in 1872 to £1,217,000,000 in 1892, but this increase of debt would hardly be considered as evidence that the railway companies were pursuing a policy which would land them in bankruptcy.

5. That the Midland district, of which Birmingham is a centre, annually consumes 3,000,000 tons of imported food stuffs, timber, iron ore, lead, and zinc, of which 35 per cent. enters by way of the Bristol Channel ports; that a capital expenditure of £600,000 would enable craft to be loaded from ocean steamers and discharged in Birmingham without transhipment, and that such an improvement might cause such a reduction in existing rates as would effect a saving of a minimum of £150,000 a year in the cost of transport now paid by the local community served through Birmingham. ARTHUR LEE.

Hayes, Middlesex,
Dec. 11th, 1904.

MILK IMPURITIES.

Sir EDMUND VERNEY, Bart., writes:—On page 74 of the *Journal* the author of the very interesting article on milk impurities advocates "that the County Council should be empowered to act in default of the local authority;" surely they are so empowered at this moment; also that "it should be the duty of the Local Government Board to intervene in the ultimate resort." I should have supposed it was their duty already. The Bucks County Council cannot be persuaded to do anything for the sanitation of the county; for several years councillors have vainly endeavoured to get the council to act, and it would be quite useless to bestow upon them powers they would be certain not to exercise.

The writer of the article sends the following reply to Sir Edmund Verney's letter:—If Sir Edmund will turn again to the article to which he alludes he will find that it is the report of the interdepartmental Committee on Physical Deteoriation that makes the recommendations to which he refers. They are on page 53 of the report. And if he will turn to the evidence of Mr. Litheby, Assistant Secretary of the Local Government Board, in charge of the Public Health Department (page 501 of the "Minutes of Evidence"), he will find that no effective pressure can at present be exercised. Sir Edmund Verney's pamphlet on "The Sanitary Condition of Bucks" shows how necessary it is that in the last resort the Local Government Board should be in a position to compel.

OBITUARY.

LIEUT.-COLONEL C. SEBASTIAN SMITH, V.D.—Mr. Sebastian Smith, mining and land agent, died on Tuesday, the 6th inst., at his residence at Shipley, near Derby. He was born on March 11, 1841, and was educated at Leamington College. He was admitted a solicitor in 1866, but early in life he became a land agent. He was an ardent supporter of the volunteer movement, and was one of the first to join the Leicestershire Rifle Volunteers in 1859, in which corps he served thirty years, retiring with the rank of lieutenant-colonel. The Society of Arts Gold Medal for exhibits in the International Health Exhibition was awarded in 1884 to the Compressed Lime Cartridge Company (Shaw Trust) for Mr. Smith's improved method of breaking down coal, and he had previously obtained the bronze medal at the Amsterdam International Exhibition. Mr. Smith was elected a member of the Society of Arts in 1888.

GENERAL NOTES.

RUBBER AND COTTON CULTIVATION IN CEYLON.—The *Ceylon Times* announces that a notice will shortly be issued giving full details of the term and conditions on which the Government is prepared to lease land at specially low rates for pioneer cultivation. These terms are that if the purchaser will undertake to plant the land with cotton, rubber, or some other product approved by Government, a lease for 50 years at a minimum rate of 50 cents per acre will be granted him, or Rs.2·50 an acre, if irrigable from a Government tank.

CANADIAN WHEAT AND AMERICAN MILLERS.—The Washington Treasury Department has taken a step that must have far-reaching consequences. The exports of wheat flour from the United States, which in September, 1903, were 1,873,981 barrels, fell in the corresponding month of this year to 850,475, and the American millers found themselves within sight of the time when their export trade would disappear through failure of home material. And so they thought then of the supplies of Canadian grain over the border. But the American duty on wheat is 8s. 4d. per quarter, and constituted an effective bar to Canadian supplies. The Washington Treasury Department now consents to regard wheat as a raw material and flour as a manufactured article, and therefore to allow upon exports of American flour made from Canadian wheat 99 per cent. of the duty paid upon the importation of the latter. The result must be that large quantities of Manitoba wheat will be diverted to Minnesota, the centre of the milling industry of the United States. Given American free trade in Canadian wheat, the Canadian farmer is likely to find it more advantageous to send his grain to Minnesota than to forward it by way of an Atlantic port 2,000 miles distant for shipment to Liverpool. It may be remembered in this connection that Mr. Chamberlain proposes to "put such a duty on flour as will result in the whole of the milling of wheat being done in this country."

INDIA AND OUR WHEAT SUPPLY.—In the *Journal* of December 2nd attention was directed to the great shrinkage in the imports of wheat from the United States. It was shown that whilst in 1900 the United States sent us nearly as much as Argentina, Canada, Russia, and India combined, in the first three months of the current year these countries sent us nearly nine times as much as the United States. The trade returns for November show a heavy increase in the imports of wheat as compared with the corresponding month of last year, but the United States sent very little of it. At present nearly half our wheat imports are coming from India and Russia, a pregnant change from the days when we got most of the wheat we wanted from the United States. Commenting upon it the very able military correspondent of the *Times* writes, "These figures are very important. They are of course liable to variations from year to year owing to the failure of crops in one country or another, but as they stand they show that half our wheat imports come from India and Russia, and that with the cessation in case of war of Russian exports of grain by sea, India stands as our first and most important source of supply. It has become the granary of the Empire. The security of India is, in its last terms, a question of the preservation of the food of the people of England."

PRICE OF MEAT.—In a paper read a few days ago by Mr. H. C. Cameron on "The Products of New Zealand, with Specific Rreference to the Dairy Produce and Frozen Meat Industries," the lecturer said that "the introduction of frozen meat to this country had not curtailed the use, nor lowered the price, of home grown meat." On the contrary the price has advanced, as shown by the following figures which are taken from a Parliamentary Return on Wholesale and Retail Prices:—

	1886. d.	1903. d.
Fore quarters of Mutton	7½	8
Hind quarters	9½	10
Legs	10	10½
Chops	13	14

The price of New Zealand mutton was the same in 1903 as in 1889, but in the interval it had fallen considerably. On the other hand there was a marked rise in American beef coming to London in the same period, as will be seen from the figures below:—

	1899. d.	1903. d.
Sirloin	9½	11½
Fore ribs	9	9½
Silver side	7½	9
Beef steak	9	11
Rump steak	12	15

No doubt the importation of frozen meat kept the price of the home product from going higher than it has gone, but Mr. Cameron appears to be right in saying that prices are not lower since the importation of frozen meat began. As shown above they are higher.

BOARD OF TRADE RETURNS.—The trade returns for November show large increases. The imports are valued at £50,670,846, an increase of £1,947,255, equal to 4 per cent., and the exports at £26,113,288, an increase of no less than £3,075,495, equal to 13·3 per cent. It has, however, to be borne in mind that the month under review contained one working day more than November, 1903. It is noticeable that raw cotton is higher in quantity by 111,195 cwt., and in value by £551,129, equal to 4·5 and 7·8 per cent. respectively, due to larger receipts from the United States. Including the entrepôt trade, amounting to £5,713,065 (an increase of £907,786 as compared with the corresponding month of last year) there was a total turn-over in the over-sea trade of November of £82,497,000, or at the rate of £989,964,000 per annum. These are record figures. It should be noted that although the receipts of wheat were much heavier last month than in November, 1903—9,270,500 cwt. as against 8,745,000—the chief arrivals were from Russia and Argentina, very little coming from the United States.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock:—

JANUARY 18.—"Wireless Telegraphy and War Correspondence." By CAPTAIN LIONEL JAMES. SIR WILLIAM HENRY PREECE, K.C.B., F.R.S., will preside.

JANUARY 25.—"London Electric Railways." By the HON. ROBERT P. PORTER.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

JANUARY 19.—"The Highlands of Sikkim." By DOUGLAS W. FRESHFIELD. SIR WILLIAM LEE-WARNER, K.C.S.I., will preside.

COLONIAL SECTION.

Tuesday afternoons at 4.30 o'clock:—

JANUARY 24.—"The Manufactures of Greater Britain. I. Canada." By C. F. JUST.

APPLIED ART SECTION.

Tuesday evenings, at 8 p.m.

DECEMBER 20 (8 p.m.).—"Street Architecture." By THOMAS GRAHAM JACKSON, R.A. DR. G. B. LONGSTAFF will preside.

JANUARY 31, 8 p.m.—"Calligraphy and Illumination." Two Papers. By EDWARD JOHNSTON and GRAILEY HEWITT. LEWIS FOREMAN DAY will preside.

CANTOR LECTURES.

Monday evenings, at 8 o'clock:—

DAVID JAMES BLAIKLEY, "Musical Wind Instruments." Four Lectures (with musical illustrations).

LECTURE IV.—DECEMBER 19.—*Flutes.* [illegible] ern limitation of the name—Action of t[illegible] air-reed—Recorders and flageolets—Cone and cylinder flutes.

Programme of Musical Illustrations. Flute Solo, *Godard*, Mr. H. Warner Hollis. — Horn Solo, Romanza, *Karl Maty's*, Mr. T. Busby.—Concertstuck, *Reitz*, Flute, Oboe, Clarinet, Horn, Bassoon, and Pianoforte, Messrs. Hollis, Fonteyne, Gomez, James, and Busby.—At the Pianoforte, Mr. R. H. Walthew.

JAMES P. MAGINNIS, Assoc.M.Inst.C.E., M.Inst.Mech.E., "Reservoir, Fountain, and Stylographic Pens." Three Lectures.

January 23, 30, February 6.

JUVENILE LECTURES.

Wednesday afternoons, January 4 and 11, 1905, at Five o'clock, CARMICHAEL THOMAS, "The Production of an Illustrated Newspaper." (Two ectures.)

LECTURE I.—JANUARY 4.—A short history of the early days of illustrated newspapers—Preparations or illustrating events—How sketches are made—Special war artists—Photography on the battlefield—The amateur photographer—Drawing from sketches Siege sketches by balloon post—Mafeking sketches by Colonel Baden-Powell—Production of process plates.

LECTURE II.—JANUARY 11. — Compositors at work—Preparation of stereos—Manufacture of paper—The printing office—Folding and stitching machines—Colour printing—Importance of good titles—The editor's waste-paper basket—Curious sketches: the Russian censor—Foreign illustrated newspapers.

The lectures will be fully illustrated by lantern slides. An exhibition of drawings will be shown on the walls.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, DEC. 19...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lectures.) Mr. David James Blaikley, "Musical Wind Instruments." Lecture IV. (Flutes: Action of the air-reed—Recorders and flageolets—Cone and cylinder flutes. With Musical Illustrations.)

Faraday Society, 92, Victoria-street, S.W., 8 p.m. 1. Mr. Adolphe Minet, "The Electric Furnace: its origin, transformation, and applications (Part II.). 2. Messrs. F. Mollwo Perkin and W. C. Prebble, "Electrolytic Analysis of Cobalt and Nickel." 3. Mr. F. Gelstharp, "The Electrolytic Preparation of Tin Paste." 4. Mr. F. Gelstharp, "Note on the Electrolytic Recovery of Tin."

British Architects, 9, Conduit-street, W., 8 p.m. Messrs. Lacy Ridge and J. S. Gibson, "Architecture and Building Acts."

Actuaries, Staples-inn Hall, Holborn, 5 p.m.

Camera Club, Charing-cross-road, W.C., 8½ p.m.

TUESDAY, DEC. 20...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Applied Art Section.) Mr. Thomas Graham Jackson, "Street Architecture."

East India Association, Caxton Hall, Westminster, S.W., 4 p.m. Mr. T. Durant Beighton, "The Possibilities of the Indian Tobacco Industry."

Civil Engineers, 25, Great George-street, S.W. 8 p.m. Discussion on paper by Messrs. Arthur Wood Hill and Edward Davy Pain on "The Construction of a Concrete Railway Viaduct."

Statistical, in the Theatre of the United Service Institution, Whitehall, S.W., 5 p.m.

Pathological, 20, Hanover-square, W., 8½ p.m.

WEDNESDAY, DEC. 21...Meteorological, 25, Great George-street, S.W., 7½ p.m. 1. Discussion on Mr. F. J. Brodie's paper, "Decrease of Fog in London during recent Years." 2. Dr. W. N. Shaw and Mr. W. H. Dines, "The Study of the Minor Fluctuations of Atmospheric Pressure."

Geological, Burlington-house, W., 8 p.m.

Microscopical, 20, Hanover-square, W., 8 p.m. Mr. J. W. Gordon, "The Theory of Highly Magnified Images."

NOTICE.—Two recent numbers of the *Journal* are missing in the set of the Public Library of New South Wales, Sydney, viz., Nos. 2,561, 20th December 1901, and 2,569, 14th February, 1902. The librarian of that library has made application for these, but unfortunately they are out of print. The Secretary will be greatly obliged if any member of the Society is able to spare these two numbers so that he may be enabled to supply them to the Public Library.

Journal of the Society of Arts.

No. 2,718. VOL. LIII.

FRIDAY, DECEMBER 23, 1904.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

NOTICES.

JUVENILE LECTURES.

The usual short course of lectures adapted for a juvenile audience will be delivered on Wednesday afternoons, January 4th and 11th, at 5 o'clock, by Mr. Carmichael Thomas, Treasurer of the Society, on "The Production of an Illustrated Newspaper."

Each member is entitled to a ticket admitting two children and an adult.

A sufficient number of tickets to fill the room will be issued to members in the order in which applications are received.

Members who desire tickets for the course are requested to apply for them at once.

CANTOR LECTURES.

On Monday evening, 19th inst., Mr. D. J. Blaikley delivered the fourth and last lecture of his course on "Musical Wind Instruments," the special subject being "Flutes." The musical illustrations consisted of solos on the flute by Mr. H. Warner Hollis, on the horn by Mr. T. Busby, and a quintet on the flute, oboe, clarinet, horn, and bassoon by Messrs. Hollis, Fonteyne, Gomez, Busby, and James. Mr. R. H. Walthew accompanied the instruments on the pianoforte.

The Chairman proposed a vote of thanks to the lecturer, and to the gentlemen who had so ably performed the musical illustrations, which was carried unanimously.

ST. LOUIS EXHIBITION.

List of Awards to Members of the Society of Arts.

The following is additional to the list as already printed in the *Journal* (see November 11, 18, 25).

Edwin Thomas Beard, A.M.I.C.E., Engineer of the Marine Drive Works, Scarborough, Silver Medal.

PROCEEDINGS OF THE SOCIETY.

APPLIED ART SECTION.

Tuesday, December 20th, 1904; George Blundell Longstaff, M.A., M.D., in the chair.

The paper read was—

STREET ARCHITECTURE.

By T. G. Jackson, R.A.

The subject on which I have been asked to speak to you to-night, is "Street Architecture." Two years ago, in this room, I had the pleasure of hearing a very thoughtful and suggestive paper on the same topic by Mr. Beresford Pite, and of taking part in the discussion that followed. The choice of his subject arose, naturally, from the alterations in the Strand, and between the Strand and Holborn, which were then either begun or about to be begun, and concerning which there was considerable difference of opinion. Since then, great progress has been made with the new streets and approaches, though it is still too soon to pass a final verdict on the architectural result. The old Strand which has delighted our eyes for so long, and which I remember saying on the former occasion had always struck me as being one of the most picturesque streets in Europe, is gone, and gone for ever, and it remains to be seen whether its successor will charm us equally, though in a different way.

It is right that when occasions arise involving sweeping changes on a grand scale, like those that are transforming this part of London at the present moment, the principles, if there are any, which ought to govern street architecture, should be sought for and examined. But these principles should not be kept for those occasions alone. These great schemes demand our attention only now and then, and it is important that the true principles of street architecture, if we can discover them, should be applied to works on a small scale

as well as to those of grand dimensions, to individual as well as to general cases. There is nothing, for instance, but good principles to prevent any freeholder from building or rebuilding his house in some incongruous fashion which will spoil a whole street. The sober dullness of such thoroughfares as Harley-street or Wimpole-street may be and has been rudely interrupted by new houses, in which individualism seems to have been provoked to excesses by the very monotony of its surroundings. The principle which has inspired these performances would seem to be a desire to show off at the expense of the neighbours, a principle not generally held to be commendable elsewhere than in architecture, and certainly not in keeping with English ideas of good taste or polite manners.

One principle, then, which ought to govern street architecture is surely that consideration should be had for neighbouring buildings. Because street architecture is social architecture, and it ought to conform to those rules of convention by whch men in society are governed. Buildings in a town street cannot indulge in the freedom that is permissible to a house in the country any more than the owner can live in town with the same easy disregard of appearances that he enjoys when he is away. In town, living under the eyes of his neighbours, he must submit to many social restraints of habit and costume in order to conform to the ways of the society in which he moves, or he will be thought an ill-bred person; and in the same way architecture, when she takes up her abode in the streets, must conform to social conditions, and show respect to the company in which she finds herself, provided of course that it be respectable. Architecture may be guilty of social offences quite as much as the architect. Violent interruptions, startling contrasts of demeanour, disregard of the conventions of society, efforts to shout down and overpower his company, which would put a man outside the pale in the civilised world, find a very close analogy in the pretentious buildings that one often finds thrust into the streets and squares of London without the least regard for the style of the work they interrupt or the scale of the buildings they overshadow. Can anyone look without irritation at the north side of Cavendish-square, where the fine symmetrically placed houses in the severe classic of 1770 are crushed by an enormous pile of nondescript architecture on one side of them; or look with satisfaction at the strange sky-scraping structure that mars the wholesome brick architecture of Hanover-square; or view without dismay the appalling intrusions that are breaking up and destroying the design of Regent-street, the one fine and consistent piece of street architecture in London? Many other instances will readily occur to the memory, where all conditions of scale and sight have been violated by the invasion of buildings which even if they would have been tolerable elsewhere, which as a rule they would not be, are doubly intolerable where they are on account of their incongruity.

These offences are more flagrant and mischievous in proportion to the architectural value of the neighbouring buildings that suffer by them. An example is to be seen at Great Malvern, where a huge pile of building has been allowed to grow up actually touching the west end of the Priory Church, and overshadowing it. There is another at Bath, where a monster hotel overtops the east end of the abbey close by. A familiar instance is to be found at Milan, where the west front of the Duomo, despite its enormous size, is crushed into comparative insignificance by the new buildings, and the prodigious front of the Galleria on the north side of the Piazza. I need not, perhaps, dwell on the mischief done to street views by the intrusion of engineering works, for this raises questions beyond the limits of our present subject. One may also hope that such enormities as the iron girder bridge across the foot of Ludgate-hill would not be permitted now-a-days, especially since railways in London have taken to burrowing like moles underground.

Nowhere, perhaps, is this architecture of self-assertion and disrespect for what is entitled to deference more offensive than at our ancient Universities. There, if anywhere, ought the public buildings, Academic and Collegiate, to be allowed precedence, for it is they that form the glory of the town and differentiate it from any other. But, inspired one might suppose by the old rivalries of Town and Gown the streets both of Oxford and Cambridge are being invaded by gaudy, vulgar architecture, as if to outshine the Colleges, reaching its climax in a smart Bank of dubious architecture and unspeakable splendour at Carfax, where the four main streets of Oxford meet.

The first principle, therefore, that I would lay down for town architecture is that there should be a consistency, a regard for the surroundings, an absence of vulgar rivalry in

display, corresponding to that consideration for others, which is the essence of good manners among individual men and women; that ordinary houses should subordinate themselves to buildings which, from their public uses or their architectual importance may fairly claim precedence; that, in fact, there should be a "comity" of conduct in architecture as well as in society; any violation of which should be condemned by public opinion as in bad taste, inartistic, and intolerable. How far we are from general acceptance of this standard of criticism, we can all judge by sad experience.

Another consideration that arises out of this, especially when there is a question of cutting through old towns and forming new thoroughfares, is that when the alterations approach or touch beautiful buildings, whether old or new, they should be designed so as fit them, and bring out their beauties and enhance their architectural effect. This is a principle that has been much more attended to abroad than with us. The Louvre must have gained enormously by the construction of the Rue de Rivoli, and the old Tuileries by the formation of the gardens and the Place de la Concorde. With us, hitherto, this principle seems rarely if ever to have been thought of, new streets and roads having been planned solely for convenience, easy gradients, and economy, with very little thought of artistic effect. What splendid opportunities have been missed, for instance, when the alterations were made at Hyde-park-corner, which, though they have facilitated traffic to some extent, have destroyed the little there was of orderly arrangement, when Decimus Burton's arch and screen stood in some sort of relation to one another. Now we have a shapeless expanse, a wilderness of irregular roads, dangerous to cross, in the midst of which float three island-refuges of various shapes, with a statue that seems to have lost its way. A still worse failure is that at the site of the old circus where Regent-street joins Piccadilly. This has destroyed Nash's fine plan, and given us an amorphous space, with the relics of the old circus on one side and nothing definite elsewhere, a mere accidental clearing in the middle of houses, where Mr. Gilbert's fountain seems to float in space without any relation to its situation. Imagine what a fine thing might have been made of this if Nash's scheme had been respected, his circus enlarged into a larger circus, or developed into a square with the fountain in the centre; or, better still, prolonged into a rectangle like the Piazza Navona at Rome, in which, besides the fountain, room might have been found on its axial line for Cleopatra's Needle, now so absurdly perched on the parapet of the Embankment, quite as one might say accidentally, without any relation to the architecture behind it, and certainly none to the river in front. It is not so that the obelisks have been treated at Rome and Paris, where they are made the focus or pivot of "place" or piazza. I could not help being struck, when walking from the Pantheon down the Rue Soufflot, with the fact that the Eiffel Tower, in the dim distance, faced me exactly on the central line of the street. The Eiffel Tower is not perhaps the most beautiful thing in the world, but so placed it had from that point of view a meaning—it acquired a certain value by its relation to circumstances and conformity to place, which it would not have had otherwise. I can hardly suppose this effect to be accidental; I would rather think it designed; but I am sure that no such conception would ever have entered the minds of our street engineers in London.

The fault, however, does not always lie with those who lay out thoroughfares in London. Considerations of economy, very properly, have to receive attention, and they very often come in to mar the fairest schemes. It does not, however, follow that these considerations should always be allowed to prevail over every other. When unusual opportunities occur of making a beautiful street, as for instance in the alterations of the Strand now in progress, it would be unworthy of a great capital to treat the matter solely or even mainly from the commercial point of view. Something must be conceded to the dignity of a great city; some generous allowance must be made for the desire of every worthy citizen that his thoroughfares should be beautiful as well as convenient. It must not be forgotten that the present chance of making a fine thing will not occur again, and that a mistake made now from a too parsimonious motive will lay up a store of disgust and irritation in the future, and a bitter regret for a wasted opportunity. This, however, is what we are threatened with in the case of the Strand between Wellington-street and the Law Courts. As far eastward as the end of St. Mary's Church there seems nothing to complain of in the frontage line adopted. A wide thoroughfare has been formed on the north side of the church sufficient for the whole traffic going eastwards. Other dangers threaten this part

of the scheme, which I will return to by-and-bye. The debateable line is that east of St. Mary's, running from it to St. Clement's, about which there has been a great deal of discussion and will probably be more.

The first line laid down by the London County Council seems to have been suggested with the intention of giving a sufficient and convenient roadway at the least possible cost. As long as it had a minimum width of 100 feet, that was enough from a utilitarian point of view, and carried with it the approval of the economists who regarded the scheme commercially. This, however, at once provoked a protest from those who looked beyond these considerations. It violated our second principle, that alterations which approach or touch beautiful buildings, should be designed so as to fit them, and to bring out and enhance their architectural effect, instead of obscuring it. Somerset-house, with its fine entrance—worthy in my opinion of comparison with that of the Farnese Palace at Rome—fortunately was not in the way; but the two churches of St. Mary-le-Strand and St. Clement Danes, planned carefully to suit the old lines of the street, presented an interesting problem for the new. It will be remembered that the first idea of the County Council was to demolish St. Mary's Church entirely, so that Londoners might drive in a straight line over its site from Charing Cross to Temple Bar, and if St. Mary's had gone, St. Clement's would, in all probability, have followed suit. The curious thing is that if they had disappeared at that time, the general public would have seen them go without any consciousness that they had lost something worth keeping. A protest which some of us published in the *Times*, was received with surprise, and almost incredulity:—

"The question of the artistic right of the Church of St. Mary's-le-Strand," writes one newspaper, "to continue and obstruct one of the main thoroughfares of London has now I suppose been settled. That the crumbling old pile is one of our most beautiful buildings from the loss of which we trust the finer sense of the community will save us is the sealed, signed, and delivered opinion of about thirty of our leading artists, architects, decorators, sculptors and actors. . . . No doubt it will be difficult for any vandal to deride the artistic qualities of this venerable ruin after so strong an expression of opinion."

This architectural critic was not alone in his astonishment at finding that Gibbs's fine church had merits. The London County Council, who received a deputation on the subject plied us with questions which showed that our objections had taken them also quite by surprise. We must do them the justice to say that when the value of the churches had been explained their destruction was countermanded, and they are now we hope safe, every subsequent plan being contrived so as to spare them.

But it is not enough merely to leave these buildings standing. Our principle requires that the new frontage lines should be disposed so as to fit the lines of the churches, and to bring out and enhance their architectural merits instead of obscuring them, and this the line laid down by the London County Council for the north side of the widened Strand signally failed to do. The difficulties were no doubt considerable; the two churches lie at different angles, accommodated to the old direction of the street, and they were both designed to be viewed endways and not sideways. To the artist's eye it was obvious that these difficulties were not met, had perhaps not even been observed by those who drew the proposed frontage line. Beyond St. Mary's it slopes away southward at a very awkward angle with the church, which will seem to stand all awry, and it cuts into the middle of St. Clement's west front, so that the church will have the effect of peeping round the corner, by which it will be half hidden when seen from the north side of the street.

The discussion which this scheme provoked was begun by a letter in the *Times* from Mr. Hamo Thornycroft, who proposed a new line considerably farther to the north and lying parallel to the flank of St. Mary's Church. This would have made a magnificent street, almost a "*place*," and have done ample justice to the two churches. It required, however, so great a sacrifice of building land as to be beyond the range of practical politics, and it was, I believe, afterwards modified by Mr. Thornycroft himself. The modification, however, did not affect the principle by which it had been inspired, which must commend itself to every artist and every one capable of appreciating the true architectural difficulties of the problem.

Other suggestions, calculated with more regard to financial considerations, followed. The Institute of Architects, who were good enough to invite me as well as Mr. Thornycroft to co-operate with them, proposed another frontage line, which was of the nature of a compromise. This, starting from the same point at St. Mary's as the line proposed by the Council, was pivotted round northwards till it cleared the front of St. Clement's Church into

which the former line had so awkwardly cut. A third line was proposed by Mr. Riley, the architect to the London County Council, which lies a little further to the south than the others, and so sacrifices less ground, but still clears the angle of St. Clement's. Both these plans naturally involve giving up a certain area of building land, and, of course, a corresponding increase of expense, Mr. Riley's plan being the more economical of the two. Poles were put up and lines drawn to show the effect of the various frontages, the result being to confirm the opinion of those who may be considered experts as to the defects of the frontage proposed by the Council. The Council's first plan, however, saved most money, and on that ground, I regret to say, it has, for the present, triumphed.

In the report of the Improvement Committee, dated October 20, 1903, it is calculated that the value of the land surrendered to the public by Mr. Thornycroft's plan was £350,000, representing rates to the amount of £5,583 a year. A plan submitted by the "further Strand Improvement Committee" involved the sacrifice of ground valued at £239,400, with a rateable value of £4,230; the plan of the Royal Institute would cost £70,000 in ground value and £1,097 in rates, and Mr. Riley's plan £59,000 in ground value and £962 a year in rates. All such calculations are naturally to a great extent conjectural, and must be taken on trust for what they are worth. For the uncommercial mind it is difficult to carry the imagination to the higher figures I have quoted. The report of the committee goes on to recite, at some length, that a width of 100 feet is "in every way ample for the present and prospective traffic," which nobody ever questioned, the objection being taken on quite other grounds. The only exception taken to their plan appears, they proceed to say, "to partake of the nature of an æsthetic proposal," which they seemed to think might safely be put aside as of no importance, and the Report was accordingly approved by the Council, and the original frontage line confirmed. The stone kerbing of the roadway is now laid down and the hoarding fixed which gives the frontage line of the future buildings, and anyone may satisfy himself of the ill-effect it will have on the two fine buildings which might so well have been worked into a regular plan on good architectural lines.

The plan will have an accidental haphazard character, with none of the dignity given by regularity, and it is one in which the very elements of true architectural treatment are not so much neglected as deliberately rejected. I venture to think that in no other capital of Europe would the economical question have been allowed to prevent so grand and important a scheme from being carried out in the best way possible.

As ratepayers, suffering from the steady increase in our municipal burdens, we are, of course, grateful when the Council lays a restraining hand on the expenditure of public money, but—

"There is that scattereth and yet increaseth; and there is that withholdeth more than is meet, but it tendeth to poverty."

On such an occasion as this, the Council could not fairly be accused of extravagance, if it sacrificed something to those æsthetic considerations which have been brushed aside as if they carried their own condemnation with them. May I be forgiven if I remark that the estimated cost of the least expensive among the proposals I have described, is about the same as that of the cheap lodging-houses or shelters which the Council are about to build, and which we are told on the authority of Mr. Loch and others will encourage the loafer and spread the area of pauperism.

It is a pity when modern improvements are so contrived as to obliterate ancient lines of communication which have perhaps become historical, or at all events bear the traces of an old civic life. Sometimes they mark the growth of a town, and the accidents which attended its expansion, and it is interesting to trace the reasons for queer twists and irregularities to circumstances of ownership, or of older settlements. For instance, till Mandeville-place was cut through, not so many years ago, High-street, Marylebone, ended abruptly near Manchester-square where Marylebone-lane falls into it. It was at first nothing but the High-street of an outlying village, in Hogarth's time still so remote and semi-rural that he makes it the scene of the Rake's clandestine marriage. It was approached from London by the narrow tortuous Marylebone-lane, that then wound between green fields and hedgerows as it now does between houses. In the same neighbourhood are, or were—for it is dangerous to speak of anything in London as still existing which one has not seen for ten years—two detached fragments of what was to have been a continuous Henrietta-street, but is cut in two by Stratford-place with no way through.

This preserves the memory of a building scheme which was baulked by the refusal of an intervening owner to sell. Portland-place, again, owes its unusual and stately width not to any grandiose idea on the part of the builder, but to the condition laid upon him not to build in front of Foley-house, which stood across the southern end. The same reason probably causes that twist in Langham-place round the hotel; for Nash, no doubt, would have liked to carry Regent-street in continuation of Portland-place in a direct line had he not been prevented. These are a few random instances of local history, not perhaps very important of themselves, one might almost say trifling, but yet sufficient to awaken interest when one comes across them, and to be worth preserving when there is no serious reason for wiping them out. But the argument carries much greater weight when one comes to the consideration of the more important historical features of a town, such as the Boulevards of Paris or the Ring at Vienna, which mark the lines of the old fortifications, or the streets of London which still define imperfectly the old Roman boundaries, the obliteration of which would be a serious loss to all who care to realise the past history of the town they live in, and to trace it in its monuments and visible features.

I think then that another principle to be observed in altering or improving an old town should be that the general lines of the main streets ought to be respected whenever it is possible, and the general conformation of the plan as little altered as is consistent with public convenience. Above all, this is desirable in the case of a city that is not only old but has been the scene of great events in the history of a nation; one whose streets possess associations that would lose much of their force if our eyes no longer rested on the stage where these events were performed. In the Paris of to-day, remodelled under the second Empire, the want of historical character must often have disappointed those who visit it with memories of the past. One would willingly spare a good deal of modern splendour if one could have something of the Paris of the Valois, or even be able to trace out better the scenes of the Great Revolution. London, which has better preserved her connection with the past up to the present, having been spared the blessing of a Napoleon or a Haussmann, is now in danger of losing it rapidly. It will be a great pity if such improvements as the enormous traffic of the day demands are carried out without due regard to historical associations on one hand, and on the other to the preservation of interesting or beautiful buildings that lie dangerously near the line of alteration.

Considerations of convenience on the one hand and beauty or sentiment on the other are seldom wholly irreconcileable; their claims may generally be met by a compromise such as that which has saved the church of St. Mary-le-Strand. To shut our eyes to any considerations but those of bare utility is to hand our cities over to the Philistines. Easy locomotion from point to point is not everything. Streets are not, or should not be mere mechanical contrivances for getting to our destination as speedily as possible; they have never been so regarded at any age but our own; one might almost say they are not so regarded now in any country but this. They should be beautiful and interesting, and so disposed as to show off their buildings to advantage, and to preserve faithfully their historical traditions; and Londoners ought to be able to take the same pride, and find the same enjoyment in the streets of their great city, that the burghers of Florence or Venice, Nuremburg or Ghent, did and can still do in theirs.

One very awkward result, moreover, would be avoided if the lines of old thoroughfares were taken in laying out new ones. Everybody must have noticed the sharp triangles to which corner houses come in most of the new streets that have been driven through crowded districts of London. They are caused by the fact that the general trend of the old streets lay obliquely to the line chosen for the new ones. In the new Kingsway, now under construction, towards the Holborn end the line is fairly square with the streets it passes through, but as it comes south the streets bear off obliquely, and this unsightly result will have the usual bad effect, unless the adjoining streets are altered also for some way outwards.

But bad as these sharp-ended sites are for architectural effect, and inconvenient as they must be for internal plan—for anybody can imagine that a room shaped like an equilateral triangle cannot be a pleasant one to live in—they are not so bad as the rounded ends and corners which have been the fashion in new streets. Rounded angles are seldom agreeable in architecture, and are best avoided. They deprive one of the firm outline and positive drawing which the eye demands in builder's work, and substitute for it a certain weak indefiniteness which is

destructive of true form, and confuses the elements of proportion. Whether in large or small buildings this rounding of the mass is equally injurious. Small buildings, perhaps, need sharp square forms and positive outlines even more than large ones, and yet nothing can be less satisfactory to the eye than these rounded fronts on a great scale, as, for instance, the Grand Hotel at the corner of Trafalgar-square, a huge pudding of a building without a single firm line to define its shape or proportions.

These rounded angles are, I think, a matter of paper architecture, by which I mean that that they look well in a drawing, and have a show of convenience which is not based on practical experience. Those long easy curves, which look well on paper, are not, I believe, found to save the horses, for they mean a long bearing on one rein, which is more wearing than turning a sharp corner and having done with it. Some of us, who have been oarsmen, will remember how much worse it was to have the rudder against one round a long curve than round a shorter one, and may form from that some idea of the views a horse might be imagined to entertain on the matter. If it is ever absolutely necessary to take off an angle for the sake of foot passengers, and I quite admit that this need may occur when there are no areas between house and street, let the corner be canted off with a flat front, which will give two bounding lines at the angles. Foot passengers, however, do not run very much against one another and need never do so if everybody observed the rule of the footway. A few more direction labels—"Keep to the Right"; put up on lamp-posts and elsewhere in our crowded thoroughfares, and some insistence on the rule by the police, who I have observed always walk on the wrong side themselves, would enable us to build our corner houses with that squareness and definite outline which is one of the first conditions of tolerable architecture.

In the original plans for the new "Kingsway" all the corners were shown to be rounded off to such an extent that some parts of the street would have resembled a row of huge band-boxes rather than a street with parallel sides. We may thank the architect of the Council, Mr. Riley, for having persuaded them to modify these extravagant curves, and substitute canted angles of more reasonable dimensions.

In the case of a street that is entirely new from end to end, such as the Kingsway, it is plain that many difficlties are absent which present themselves when it is a question of altering an old one, where there are buildings that must be respected. This is particularly so in the matter of scale. The buildings that are to line Kingsway may be as large as they please; there is nothing to compare with them, nothing that they would injure by overpowering it. They will only be judged by one another, and there is nothing to confine them to any established proportion. In the case of the Strand this is not so. The proper scale there is given by the two churches and Somerset House. These are public buildings, and in every view of the street they have always predominated very happily, as they are entitled to do, over the private houses around them. Here is a scale to which on artistic grounds the new buildings must conform if they are not to spoil the picture. Unfortunately this is not likely to be a consideration with either the London County Council or the lessees and purchasers of the new sites, if one may judge by the beginning that has been made. The new Gaiety Theatre is far enough from St. Mary's to do it no particular harm, but an enormous building has been run up to a still greater height next to it which overtops both theatre and church. If this is to give the scale of the other houses that are to follow on eastwards the churches will be reduced by comparison to the size of toys; their architectural importance will be ruined, and the street view will suffer. I sincerely trust it is not too late to put some limit to this overbuilding and to induce the Council to fix a height for the Strand front which will be properly proportioned to the scale of the old buildings which give the Strand its particular charm—a charm, however, which may easily be broken by injudicious and disproportionate surroundings, Let the houses in Aldwych and Kingsway adopt a scale of their own, but let the Strand front be restricted to the scale given already by the fine buildings which will remain the greatest ornament of the street if it is judiciously laid out. There is a serious danger lurking behind the words of the report by the Improvements Committee, that "it will be possible to secure under the Council's scheme an imposing effect for the buildings to be erected on the northern side of the Strand." We do not want an imposing effect on the north side of the Strand. We want houses, lofty perhaps, but of a reasonable loftiness that will not crush the public buildings into

insignificance, nor contrast too violently with the buildings on the other side of the way. Let the imposing effects be reserved for Aldwych and Kingsway where they can have the field all to themselves and injure no one.

And yet even there I think we may express a hope that that megalomania which is one of the vices of the age will not be allowed to run riot. The sky-scraping architecture of New York is fortunately illegal in this country, but without breaking the law we can and do get nearer the sky than is agreeable to those who walk on the earth. In hot countries where the sun is an enemy to be shut out, narrow streets between lofty houses are reasonable. But in England the sun is a visitor who never or very rarely outstays his welcome, and we want as much of him in our streets as we can get. The houses of Regent-street and Oxford-street, and of the untouched parts of the Strand, have always seemed to me of the ideal height for our dim, murky London climate. Those streets always look bright and cheerful, while, for sombre melancholy and awful gloom, I know nothing to approach Victoria-street, Westminster, with its monster mansions on either side.

As things are however at present, it seems that those who build along the new frontages will be allowed to do much as they please in the matter of height and style. The only condition is that they shall submit their designs to the London County Council, who it is supposed will form a committee of taste to pass or reject what is shown them. This suggests another question as to the best way of laying out street architecture on a general scheme. Should it be treated as one whole—a single design to which every builder of a part must conform, or is the building line to be the only rule to which everyone must work, all else, style, scale, and architectural treatment being left to the individual taste of the several builders? Is the architecture of the street to individual or collective, accidental or regular? There is much no doubt to be said for either alternative. If we recall to memory the streets that have delighted us above all others in our travels, I fancy the picture that will rise in the mind's eye of most of us will be the street irregular, winding perhaps among the magpie black and white houses of Shrewsbury, or the carved and overhanging timber fronts of Hildesheim which seem almost too quaint to be off the stage of a theatre; or the High-street of Oxford, with its stately series of colleges and churches set off by the more modest buildings that serve as a foil to their beauties; or the arcades of Bologna and many an old Italian city; or the shadowy eaves of Berne and Lucerne; or Lisieux with its slated house fronts; Caen and Rouen; or such streets as abound in the old cathedral and county towns of England, with fronts of mellow brick or hoary stone, and here and there a glimpse of a trim garden or masses of foliage from overhanging trees—these are the streets we love and of which we cherish the memories rather than the formal splendours of modern improvements. But these streets that we love are not to be had for the asking. They are the outcome not of design but of accident. They are the creation of individualism, of each man's desire to house himself according to his own taste, and so each house has in its degree an historical interest. The result is not so much architectural as picturesque. The Strand of three or four years ago was, and the western part of it still is, a street of this kind, eminently picturesque, deriving its interest from variety of colour, skyline, and height, all combining when seen in perspective into a certain agreeable confusion and intricacy of detail that was pleasing, although when one came to examine the buildings severally, except the few that had survived from the 17th or 18th century, there was hardly a good one among them. Such a street cannot be designed, it must come of itself, and it requires time and weather to ripen it to perfection.

But the new Strand cannot wait for time and weather; the buildings along the new frontage have begun to rise and will continue to spring up with magic rapidity. The north side of the street will soon be lined with buildings of some kind or other, and the question is whether they should be drilled into regularity as was done in the case of Regent's-street and the terraces on Crown land facing the Mall and those in Regent's-park, or else be left to the individual taste of the owners, subject only to their satisfying the taste of the County Council. The latter is the plan proposed at present, though perhaps it is not too late to revert to the other should it be thought desirable. I confess to regarding the unrestrained or practically unrestrained genius of the commercial architecture of to-day with misgiving. If we may judge by what is now going on in the Brompton-road the result will probably be a competition in which every house will try to outshine its neighbours by cramming on more ornament, overpowering

it in splendour, and overtopping it in height. Better far than this the monotony of Gower-street or the unloveliness of Wimpole-street—but the days for sober building of that kind it is to be feared are gone for ever. The tide of self-advertisement is rising; it has risen high enough to capture the last stronghold of journalism, and it has laid nine-tenths of our architecture at its feet. It is held that architecture to be good must be smart; art is supposed to consist in ornament, and ornament is valued in proportion to its quantity not to its quality. Nothing has done more to help this principle into practice than the introduction of terra-cotta as a building material. After the first cost of the model, it is as cheap to cast ornamental work as plain, and as the ornamental work makes more show for the same money, there is no end to its abuse. To the fatal facility afforded by this dangerous material we owe the trimmings round door and window which have violated the respectability of Russell-square, the unspeakable gorgeousness that disturbs the repose of the purlieus of Berkeley-square, and the elaborate arcades and great dome that seem to ride insecurely on the edge of plate-glass windows in the Brompton-road. It is a great pity that terra-cotta should have been so misused. Properly employed as it was in many towns of North Italy, notably at Cremona and Pavia, and in the fine roundels at Hampton Court, or the tombs at Layer Marney, terra-cotta is a noble material, and when glazed it may rise to the dignity of Robbia ware. But cheap repetition of ornament vulgarises it; when once used the moulds should be destroyed except in case of simple mouldings, or such conventional embellishments as the egg and dart, or dentils, and such like simple ornaments which alone admit of repetition to any extent without awakening feelings of fatigue and disgust.

But the mention of plate-glass reminds me that I have scarcely time left to speak of what is perhaps the crucial difficulty of street architecture, namely, the shop window. In this age of display and self-advertisement, when commercial modesty would seem to have fled like Astræa to the heavens, it is thought necessary to abolish the front wall of the ground floor, and substitute huge sheets of plate-glass behind which the wares can be exhibited in lavish profusion. There are a few exceptions, but very few. I suppose a tailor who broke out one of these large windows and displayed his wares instead of the usual wire blind would lose his customers; and now and then one finds a shop deliberately retaining the modest window and small panes of 50 years ago, and I think one always feels instinctively that the wares in that shop must be above average. But the rule is the other way. These open shop fronts have come—as the slang phrase goes—"to stay," and architects will have to reckon with them just as the sculptor has to reckon with the modern trouser and frock coat, which cause him equal distress and perplexity. Accepting, then, the great plate-glass ground floor as inevitable, how are we to treat it architecturally so as to make it tolerable, or if possible more than tolerable, actually an element of beauty in the façade? For it ought to be possible to do this if it is one of the glories of architecture, as we believe, to accommodate itself to circumstance and necessity, and not only to construct suitably but to satisfy the eye and give pleasure by expressing the conditions of the construction.

This, then, is the problem. The ground storey must have no front and no partitions and no supports except against the party wall on either side; but the upper storeys must be enclosed for habitation and be divided by partitions into rooms. The whole mass of this upper part, sometimes of enormous height, has to rest on an iron girder at the ceiling level of the ground storey, a girder which has no supports but an iron stanchion at each end. How are we to treat this on the orthodox principle that architecture should be the expression of the construction, when the real construction of such a building has so little with which to appeal to the eye? It may of course be argued that the old construction with piers and arches satisfied the artistic sense and pleased the eye because we knew from experience that it was sufficient for support, and that when we find from experience that two steel stanchions and a beam across them will do as well, our artistic sense will or should adapt itself to the new conditions, and rest equally satisfied in them. This is no doubt a hard saying, but yet there is truth behind it. To bring this construction within the domain of art it is only necessary that it should be visible. What support there is must be seen, for art only deals with what meets the eye. It will not satisfy the artistic sense to know that the support is there unless it can also be seen, and then the eye, appreciating the difference between the properties of iron and those of brick and stone, may learn to be satisfied, and admit the novel construction

into the domain of art. There seems no reason why the stanchions and bressummers should not be shown and treated architecturally. But so far from this being done now, the practice is to hide them carefully as if there were something disgraceful in being obliged to prop the upper storeys, and the necessary columns or stanchions are either concealed behind stone facings to give a fictitious appearance of stone construction, which, if real, would be wholly unequal to its apparent duty, or else they are encased in mirrors which prevent their being seen at all. So long as the building appears to be supported on the edge of its plate-glass shop-front its architectural redemption is past hoping for.

The same inconsistency prevails in the upper storeys. The solid lower storey is done away with to suit a novel requirement. But the builder puts above it just the same upper storeys that would have been there if the lower part had been built in the old way. This cannot be right: so radical a change in the supports ought to affect the character of the whole elevation. We cling to the old traditions in one part though we abandon them in the other, and the result is ludicrous when it is not offensive. What can be more ridiculous than the oriel window we often see insecurely balancing itself on the middle of a girder? These features belong to the old way of building, and have no place in the new. Till we recognise this and make up our minds that if we accept the new mode of construction by iron we must break definitely with the traditions of brick and stone, there will be no hope for us.

The best solution I can suggest is that as the lower storey must be of iron construction the upper storeys should be so too, as far as is consistent with their purpose. To manage this we must start with a full recognition of the difference between the properties of iron or steel and those of stone or brick. The strength of masonry or brickwork, setting aside the cohesion of mortar which should be regarded rather as an accessory, consists in its weight and its resistance to downward crushing loads. If exposed to lateral force its stability depends either on its *vis inertiæ*, or on the equilibrium of forces acting in opposite directions. It has no tensile strength and no elasticity or very little, and the only lateral tie it has to depend on is that of the bonding or interlacing of the stones or bricks that compose it. Contrast this with the methods of carpentry. Timber construction has all the properties that are wanting in masonry or brickwork. It has tensile strength and elasticity, and it can be framed so as to tie the fabric securely together. Good carpentry hangs together by its joints and framing, and will submit to considerable distortion before it gives way. The half-timbered houses of England and France afford many instances of this: they are often out of the perpendicular, leaning forward, falling backwards, or inclined sideways, and yet, so long as the timber is sound and the tenons hold, they remain secure.

This half-timber construction, be it observed further, is a reversion from arcuated construction—it is in the literal sense of the word a *trabeated* style—a style of posts and beams, quite as much so in its own way as the Parthenon and the older buildings that preceded it, and reproduced in stone the elementary forms of wooden construction.

Now, in these half-timbered houses I think we may find a suggestion of what might be done in the way of construction with iron and steel. Iron construction, after all, is very like carpentry. It is a trabeated style. It has the tensile strength, the rigidity, and the elasticity of timber, but in a superior degree, and it hangs together by its joints, cleats, and bolts, much as carpentry does by its tenons and mortices. Just as the half-timbering forms the skeleton of a Surrey cottage or a Shropshire mansion, which is filled in with the flesh and skin of brick nogging or cob and plaster, so might a skeleton of iron framing contain a similar wall-veil or curtain to make the interior of the upper floors habitable.

Let us imagine, then, the street front of a row of shops below with several storeys above. The supports of the great bressummer would be exposed to view, made preferably of cast-iron, and between them, not as now in front of them, would be the great plate-glass screen enclosing the shop. The bressummer itself would also be exposed to view, protected by some salient feature to throw off the wet, and thus the eye would be contented by the exhibition of the supports. The upper storeys would be formed by a skeleton of iron or steel, filled in with brick or stone, but showing itself on the surface just like the half-timbering which was its precursor. The strength of the building would consist in this framing, and the filling in might therefore be only so thick as was necessary to secure an even temperature in the rooms. Probably two four-and-a-half inch walls with bonders and a hollow space

between would suffice, the inner lining being contrived so as to cover the iron frame and prevent mischief from condensation. The interior partitions would, of course, be formed in the same way and the floor would naturally be constructed of iron and concrete. Following again the precedent of half-timbered houses, the upper floors might be made to overhang by projecting the joists of each storey successively beyond the face of that below. In this way I can conceive an admirable effect being produced. The filling in might be either plain or modelled with plaster in relief, or faced with glazed bricks or coloured terra-cotta, or decorated with sgraffito, or treated in a dozen different ways suitable to the embellishment of plain surfaces, for let us hope there will be no oriel windows hanging in air, nor any fantastic freaks such as we are now suffering from.

M. Viollet-le-Duc in his lectures on architecture — lectures which, like the Verrine orations, were written but never delivered—has several sketches for construction with iron supports. Some of them are suggestive but the majority seem to cling too closely to the Gothic art he loved, to be pleasing in combination with the new principles he is advocating. Gothic vaults of masonry, springing from stone capitals which have no columns below them, but are supported by inclined struts of iron projecting from a distant wall, do not impress one favourably, nor does there seem any object in retaining the Gothic vault at such a sacrifice. But he shows a street front constructed somewhat in the manner I have described, which commends itself at once as sensibly contrived.

Whether or no anything of the kind has ever been built I cannot say. It seems to me an experiment that it would be most interesting and instructive to carry out.

Whether this iron construction will prove durable or not is another question. One has been told that the life of a girder exposed to changes of temperature is not more than that of a generation. It depends a good deal on the thin skin of paint that protects it. What will happen in the inside of box-girders that can never be painted remains to be seen. What will happen in case of a great fire is also a grave question. But after all, these buildings are not intended for immortality; if they last for a generation it may be enough. The constant changes that London undergoes make doubtful the permanence of anything one does. A house I built in Dover-street some seven or eight years ago has been already pulled down to make way for a station on the Tube railway. The great mass of Walsingham-house, just destroyed, and about to be replaced by a monster hotel, had only enjoyed a life of some 20 years. It fell to my lot to demolish an expensive marble staircase and entrance hall of one of the city Companies which had only been built thirty years. Thirty years hence the new marble staircase I made in another part of the building will perhaps follow its predecessor into oblivion, and the city Company itself may conceivably have ceased to exist. The changes in London are so incessant and of late so sweeping that he would be a bold man who would prophesy a long life to any building in it whether old or new. The number of Sir Christopher Wren's fine city churches is being diminished. One by one they are being pulled down and their sites covered by banks and offices. Huge piles of chambers cover what ten years ago or less were the pleasant retired gardens and courts of New Inn and Clement's Inn, and Clifford's Inn is doomed to a similar fate. If these monuments of architectural and historic interest are unable to save themselves why should we expect or wish for the ordinary shop front more than an ephemeral existence?

But though street architecture may be evanescent, the streets themselves—at least the more important of them—will probably continue to run on their present lines more or less, and if, as now happens, any great innovation has to take place it is important that the new lines should be properly laid down. When one considers the enormous cost of altering the Strand, it is not likely that it will ever be altered again for centuries, and I would once more express a hope that the success of the new plan may not be imperilled by any misplaced economy. It may not be too late to persuade the London County Council to reconsider the decision in favour of their original frontage line and to place some restriction on the scale of the new buildings facing the Strand. Possibly the important society I have now the honour of addressing might bring its influence to bear on the matter. Æsthetic considerations after all do go for something though they are lightly esteemed by the Improvement Committee. Never was there so much talk about the advancement of art and art education. Art schools cover the country, national prizes and scholarships are showered on the students, and we shall surely stultify ourselves if, when the time comes for putting

our pretended interest in art to the test, we choose the worse way of doing an important work instead of the better from purely utilitarian motives.

The SECRETARY of the Section read the following letter from Mr. Walter Crane:—I should have liked to have been present at Mr. Jackson's lecture on Street Architecture — a subject which in the present state and transformation of London one would think must claim universal attention. We seem to be in a terrible fix. The appalling cost of the ground in London, owing to our having allowed private owners to reap the fruits of the community to which it owes its value, stands in the way of really drastic improvements, and makes the struggle with London traffic almost hopeless, and the effect of our street architecture dependent upon such clearances as can be made to relieve the congestion of such traffic. The policy of huge stores and flats upon the top of plate-glass walls knocks everything else near them out of scale; while posters and mammoth lettering for commercial purposes make even the best efforts of the street architect look ridiculous. We have tasteful and capable architects among us, but somehow their influence is not so great as it ought to be, and even their efforts are liable to be stultified by the commercial monstrosities alluded to. The great fire of 1666 gave Wren his opportunity. The great clearances of the London County Council ought to give our best modern architects their opportunity, but our chance of gettting really beautiful buildings or streets seems quite haphazard under our present system. Why should not every municipality have a council of advice on architecture and street arrangement?

DISCUSSION.

The CHAIRMAN said he thought the great problem was to impress upon municipal bodies—of course, primarily in London, but also over the whole country generally—the importance of æsthetic considerations which were now so much neglected. From his experience of various municipal bodies, he thought one of the great difficulties was that the work of the municipality was necessarily very hard and very tedious work, and it wanted a certain class of men to do it. Unfortunately one did not often find the æsthetic perceptions combined in the same individual with that sort of character which would lead that individual to go day after day to his county or town-hall, and toil over committee work. He thought that was the real point. He did not think as a rule the municipal bodies fairly represented the taste of the nation. By a process of natural selection, they might be said to represent what was somewhat below the average taste of the nation. A great deal was heard about art nowadays, but, in his humble opinion, not nearly enough importance was attached to architecture as an art. Too much time was spent over drawing and painting without considering architecture. He had long considered that the glory of architecture was that it was the poor man's art. The exterior of a fine building was equally visible to all, and, moreover, it was a lasting art: the average duration of a building was at least two or three centuries. Other works of art as a rule were inaccessible to the public, and only to be seen on special occasions. Architecture was in every respect a most difficult art. That, he thought, was evident from the number of architects who did not succeed conspicuously in their profession. It was extremely difficult for the amateur to acquire sound ideas upon the subject, however much he might desire to do so, and it seemed to him that that was a great gap in English education. If architecture were more taught, especially in association with history, and if it was taught in connection with such elementary teaching of art as was already in existence, people might have better canons of art. The author in his paper said that people did not know what was good art and what was bad, and until they did know what was good and what was bad, it was hopeless, he was afraid, to expect them to do what was good. The most hopeless thing to his mind in the present day in town architecture was the height of buildings. At the same time, looked at in the spirit of compromise, he did not see the slightest hope of restricting buildings to a lower height than that allowed now by law. As they knew, a limitation was imposed not very long ago. The great cost of land, and the great desire of everybody to be as near the centre of town as possible, made that inevitable. London was not so bad as New York. He was afraid that poor St. Mary's—he was pleased to have been connected with the preservation of the church—would be smothered by the imposing structures on the north side of the Strand, when the County Council succeeded in selling the land, but even that would be nothing to the fate of Trinity Church in New York, which stood between two skyscrapers, and could not be discerned unless one was right opposite it. As a general rule, the fates were on the economical side rather than on the side of doing the thing well. There was one point to which the author did not allude, although he knew that he recognised it, viz., the constant warfare that was waged against the best buildings of the architect by the bill-poster. There had been two widenings in the Strand, and anyone going through the Strand, and looking to the east or west, would see at the widening that the blank ends of the adjoining buildings were covered with advertisements, which always suggested that the building was not finished. He saw a member of the Improvements Committee present, and that gentlemen and himself endeavoured to purchase one of the houses, but unfortunately it was a public-house of enormous value, and the owner of the house persisted in sticking advertisements upon the wall.

Sir John Wolfe-Barry, K.C.B., F.R.S., said he found himself very much in accord with all the author had contributed to the question, which was one of great importance. He thought the time was very opportune for the matter to receive public attention, because, as most people knew, there was a Royal Commission sitting upon the question of the congestion of traffic in London. He thought anybody who read the evidence given before that Commission would realise that whatever might be said about the necessity for better modes of locomotion, the broad fact stood out conspicuously that the streets of London were inadequate for the traffic which they had to accommodate. Some people seemed to think, and he rather fancied that that was the trend of the evidence given by the police, that the traffic should be made, by a variety of restrictive regulations, to fit the streets, but he did not think that was the reasonable thing for a great city. The streets ought to be made suitable and adequate for the traffic of its inhabitants. In all probability, dating from something like the present time, there would be a great effort made to make new and wider streets in London to fulfil the object which was now most urgent, and which could be assessed, even in a money point of view, as entailing, from the narrowness of the streets, an enormous loss to those who daily frequented them. It was interesting to see that the money loss, such as it was, fell more particularly upon the wage-earning class, and it is to be remembered that they formed the class of all others to whom time was money, more so perhaps than to even the middle classes of the community. That being the case, it seemed to him highly probable that large street improvements would be the order of the day; and it was most desirable that the street improvements should be considered in an artistic as well as from a utilitarian point of view. He did not know that he would go quite so far as the author in saying they should consider the artistic point of view first. He thought the great point for a new street was that it should adequately accommodate the traffic in the direction which was most convenient, and he had not the least doubt in the world that the modern architects would rise to the occasion just as the older architects did, and would deal with the problem which they had to solve, the main lines being more or less prescribed as matters of necessity. In that connection he most cordially agreed with the great desirability of considering the question of vista, and the grouping of streets and public monuments. He thought that had been much neglected in London, with very great disadvantage. The only real effort historically in that direction was the valuable work of Nash in the laying out of streets in the time of the Regency. There was some attempt made then in making the street point in a direction which was agreeable, and in placing public monuments where they could be seen in proper directions. When they came to consider the more immediate question of the paper, the modern style of street architecture, he could not help thinking that the architect of the future must discard a great deal of what he had been taught of Grecian, Roman, and Gothic architecture, which only fitted special buildings, and was not suitable for the commercial life of the present generation. Just as the freer style of architecture took the place of the more cramped style in former times, so in his humble judgment the modern architect would have to study steel and iron construction, and show them how it could be made artistic. He was, from the point of view of taste, one of those benighted persons called civil engineers, and, therefore, he would not express any opinion upon what was artistic and what was not, but he was quite certain that the architect of the future must make steel and iron work to serve his purpose as an artist. Thus he thought it was most valuable to hear what the author had said on what he called the trabeated form. It carried the germ of what he (the speaker) had in his mind, which was a development of structural steel and iron work to produce a harmonious whole, and for himself he did not see why that should not be the case. They knew that very beautiful things could be done in steel and iron construction. He always admired extremely Southwark-bridge, which was a building of a most bold conception made of cast-iron. He thought it would be very difficult to improve on some of the lines of general beauty of Southwark-bridge, and he could not see anything but encouraging results in Blackfriars-bridge, the great arches of which were, in their way, quite as beautiful as a stone arch. If it was right to discard the idea of stone construction when stone limited the span of arches in a way that was inadmissible in their work, why should not it be right to adopt the same idea in the design of domestic architecture? A shop window was a necessity of commerce; if that was recognised—and he did not think anybody for a moment could doubt that it must go on—the trabeated form was the form which could best adjust itself to the conditions. How that was best to be done was a matter which he thought could be left to the best architectural talent of the day. That was the problem that had to be faced, and he was quite certain it could be faced by persons of the attainments of Mr. Jackson, and other architects who gave their mind to it. He could not help thinking that architects up to the present time had been too much the slaves of construction based upon materials which were no longer capable of fulfilling the work of modern requirements. Until they shook themselves free of those fetters, people would always be confronted with bastard styles of construction, which were ludicrous in themselves and did not satisfy the eye as to strength or fitness. He recollected the navies of the present day being quoted as an example, and remembered when people said nothing could be more hideons than the modern iron ships. But they had come to stay, and, to his mind, apart from the sails of former times, the hulls of the modern ships

were quite as beautiful as the old wooden ships which they had replaced. He did not mean to say that two or three funnels on a ship were as beautiful as a cloud of sails; but when one got rid of the idea of a sailing ship, the hull of a modern ship was every bit as beautiful as the hull of an old three decker. He thought everybody was much indebted to an architect of the distinction of Mr. Jackson for coming and telling them so frankly that what was to be done was to deal with the necessities of commercial architecture. It was a new departure, he thought, in architectural discussions. It seemed to carry with it the ideas which they ought to follow, namely, that it was perfectly hopeless for architects any longer to consider that they could make commercial requirements fit the architectural knowledge of 200, 300, or 500 years ago! Iron construction was the construction of the future. It had so many advantages that it was not likely to be set aside, and he thought it was most encouraging that Mr. Jackson should have indicated, however slightly, the way in which he would deal with what he called the trabeated form of architecture, and so render it possible to adopt sound idea of proportion and detail to the comparatively modern building material of iron and steel.

Mr. REGINALD BLOMFIELD said that as a member of the humble profession of architects he had been particularly edified with Sir John Wolfe-Barry's remarks. Architects knew that their shortcomings were very considerable; they were used to being lectured, and even sermonised, by eminent engineers, and were very grateful to them for it. He was very glad to hear what engineers expected of architects, but he could not precisely follow Sir John Wolfe-Barry in one or two of his remarks, because he pointed out that iron and steel should be of trabeated construction, and then stated that he could not see the difference between the iron arch of a bridge and the same arch in stone. There seemed to be something wrong there. Then again Sir John asked architects to show how iron and steel were to be treated in an artistic way, but surely that was the engineer's business. Architects were waiting for the engineers to show them how they were to deal with iron and steel, and they would be only too delighted to follow their lead. He was grateful to the Chairman for having made some appreciatory remarks of the profession of architecture; he realised that it was a profession which had a good deal to think about, and which ought to be consulted more than it was at present. The subject of street architecture was a very important one, which had apparently been very little studied in this country; in fact, the public seemed to be altogether indifferent on the matter. The author had formulated three very valuable principles in regard to the method of dealing with the proper principles which regulated street designs, the first concerned the designers of houses and buildings in streets, and the other two were addressed to the authorities who controlled the designer. The first principle he termed very happily the principle of architectural comity, which was a point that all architects ought to lay to heart a great deal more than they did. There had been some glaring instances lately of the total disregard of adjoining buildings with disastrous results. He did not think any artist, if he seriously considered the matter, would entirely ignore the setting of his building, and he thought it would be unsportsmanlike of him not to consider the interests of adjoining buildings as well. The difficulty was, who was to control the man. If there was a committee, or even a Ministry of Fine Arts, they were not much more than a stalking horse for the professional man behind them, and he did not think there was at the present moment in England a sufficiently established authority on the standard of taste to warrant the establishment of such an artistic ministry. In France, where such things were done much better than in England, the great superiority was due to taste, which dated back many years. There was nothing of the sort in England, and he was afraid that all they could do was for individual designers to appeal to architects themselves. The other two principles which the author formulated were, first, the principle of vista, and, secondly, the conservation of places of historical interest. He thought they were both excellent principles, but did not think they were quite compatible. The author had given an interesting example of how the house at the end of Portland-place prevented the continuation of Regent-street right through to Portland-place. What was wanted was some definite principle of the designing of the streets. There was no doubt that streets could not grow; they had to be designed and laid out, and it seemed to him that the proper principle to control them was really the æsthetic one, *i.e.*, architectural and artistic considerations, of course after utilitarian purposes had been satisfied. In order to obtain that there must be some controlling spirit. The author had congratulated the London public on never having had a Haussmann or a Napoleon. He did not agree entirely with that, because some such spirit as a Haussmann was wanted if a great vista was to be obtained, and Napoleon cleared the way to a large extent for the very stately city which Paris was at the present day. There was no such thing in England, and the authorities did not seem to be conscious of the possibility of it, and it was to that they owed such horrible fiascos as had distinguished the work of the London County Council. Northumberland-avenue appeared to have been laid out so that the eye settled on the signal posts and the lamps of Charing-cross bridge! He hoped better things would come out of the Strand improvement than had happened so far. The difference would be seen if such undertakings were compared with those carried out in Paris. In the Place de la Concorde there were grand views on

all sides. In the Place de la Opera, although he did not admire the Opera House, he admired the way it was placed. Then the very fine new bridge, "Alexander the Third," had been laid with direct regard to the Invalides at the end of it; and was one of the finest things in Europe as a piece of municipal architecture. It was not only a question of placing the things, but spacing them, and in England there was no idea of scale at all. He thought the biggest square in London was Russell-square, and a terrible affair it was at present. The biggest public parade in London, apart from the Horse Guards Parade, was Trafalgar-square, and compared with any of the famous 'piazzas of St. Mark's, or St. Peter's, or Milan, it would be seen what a rubbishy affair it was. He thought the corner of the crescent in the piazza at Milan was about 500 paces, whereas Trafalgare-square was the same in feet, which showed how deficient England was in that respect. Another instance was the City-square at Leeds. There was a figure in the middle by an eminent sculptor, and around it many charming figures holding lamps; there were four statues exceedingly well done, but the whole effect was stultified by a poor sort of balustrade of Aberdeen granite quite out of keeping with the rest of the monument. The real gravamen of the paper was that such things were left to people who had neither time nor ability to study them. The author had described, with a great deal of quiet humour, a really touching surprise of the London County Council that the church of St. Mary-le-Strand had some architectural merits, and he also described the very agreeable candour with which they amended their decision in regard to it. He hoped that might be a sign of better times, and of some awakening intelligence; he hoped the paper would rouse them up to a keener sense of their duties as the guardians not only of the pockets of the ratepayers, but also of the beauty of the city in which they had to live.

Mr. J. J. STEVENSON thoroughly agreed with what the author said with regard to Piccadilly-circus, where so beautiful and regular a scheme was turned into an amorphous fiasco. It seemed to him that had arisen from those who laid it out endeavouring to make the most curved lines so that a cab should have no serious turnings to make. Another thing which he thought those who laid out streets placed more stress on than was necessary wes that the widths of the streets necessary produced a good architectural effect. After all people walked on the ground, and what was required was that the size of the streets should be in a sense proportioned to the size of the building. In laying out streets a great mistake had been made through the mania of making them perfectly straight. Straight streets always produced the most dreary effects. All the beautiful old streets of the world had been erected, not in a straight line but curved, and one reason why that produced a better effect was that the buildings were turned towards the onlooker. That was most noticeable in Venice, where not only the buildings were turned, but where they were separated from each other by narrow canals, so that each building had a side as well as a front. He believed that was one reason why the author very properly said that the old Strand, with its comparatively poor buildings, produced a great artistic effect. It might be difficult nowadays to have other than high buildings in streets, where considerations other than artistic beauty applied, but one hoped that, at least in the country, they would have been allowed to make buildings which were picturesque as well as convenient. He thought one of the great calamities of recent times had been that, almost all over the country districts, the new municipal laws were importing into quiet country districts what were really little bits of the mean streets of London.

Mr. T. BLASHILL said that Mr. Blomfield had confirmed what he himself thought, namely, the difficulty of laying down any new principles unless they were permanent. In his experience taste had radically changed every 20 or 25 years; there was no kind of permanence about it. He never heard of the picturesqueness of the Strand until quite recently; it was never thought of until quite modern times. The author had deprecated the alterations which were made in Harley-street. He called to mind some 40 or 45 years ago the howl of derision with which a company of gentlemen, in such a meeting as the present, received Mr. Beresford Hope when he spoke of the architecture of Harley-street and Upper Baker-street. Nothing would induce him to live in Harley-street; it was a narrow and gloomy street; and even if the whole of it were rebuilt and made as lively as the author feared, it would not come up to his scale of cheerfulness. The author had spoken against terra cotta and oriel windows. He remembered when terra cotta was looked upon as the coming salvation of architecture; everybody rushed for it, and it was simply the impossibility of getting the material within six or eight months that prevented the whole of the buildings of London then in course of erection being built in terra cotta, and now Mr. Jackson was discouraging it! Then the author had said that consideration should be given for neighbouring houses. Of course, they all liked to be polite, but he did not think any of the buildings which they admired, whether old or new, had been dictated to any great extent by consideration for the neighbours. That very fine building at the corner of Pall Mall and St. James's-street, the Alliance Bank, a rich building, not only in its outline but in its decorative features, seemed to him to have been dictated not very much by the architecture near to it. The author was in favour of designing neighbouring houses to accord with a particular structure. One instance of that was the bridge at Conway, and the imitation of the Castle, which most people would wish was not there, so that there was something to be said on both sides. With regard to the Arch at Hyde-park Corner, he would say ten times

as much as the author if he could on that subject. If he remembered right, that piece of business was arranged by the Commissioner of Works without much appeal to public taste. They heard one day that it was going to be moved at a cost of £10,000, and he thought most people wished that the arch had been kept where it was; in fact, it was worth £10,000 to put it back again. The author had raised the question of individualism and collectivism. He was strongly of opinion that individualism was likely to prevail in the future, and he thought it ought to. People who spent money on buildings would not spend it to please the municipalities; in fact they were not very anxious to take public advice at all. If the public wished elevations to be made to suit them they would have to pay for it in some shape or another. The Holborn-viaduct was begun with the intention of making everybody build to one design, but owing to the restrictions the land was not built upon for some years. The same thing happened with Northumberland-avenue. People were not anxious to take such property. He wished to make a few remarks about the method of getting rid of land for building purposes. It was now let by auction. When land was let by auction to a person, even although his plans had to be approved, there was a limit of time in which one could reject his attempts to make a decent design. In the case of the streets which Mr. Blomfield had mentioned, there was great anxiety on the part of the public authorities to get the ground covered. One could not confiscate the man's right which he had obtained by buying the land at auction; the land would have to be sold or let again, which would mean delay, and probably it would not sell at the same price as before. Why should not the authorities in London, if they desired to have control, make it clear that they had certain plots to let, and wanted a certain amount of money for them? If that were done an entirely different state of affairs would arise. Under the old style a certain set of architects made it their business to get hold of the land, and whoever wanted to build on it must get the land through them and adopt their designs. He thought that was the root of the difficulty. If the plan which he suggested was followed any man who wanted a plot would go to some well known architect, get a good design at no great expense in order to show what he meant to do; he would then go with that design to the County Council, and say he would give so much for the plot, and show the sort of building he intended to put on it. In that way the design would be seen before the bargain was made. Under the present system the thing was settled in the auction-room, and then a fight began between the Council and its tenant.

Mr. HALSEY RICARDO exhibited a diagram which expressed his views on the principles on which one might construct a street, showing some of the possible advantages of the trabeated style of iron and steel work. The overhanging of the upper storeys would give shelter to the ground floor. In order to get a wide street, the upper parts of the building would be set back in order to let more air in. The people in the residential rooms on the top storeys would have a little forecourt, which they could use for observing what was going on in the street below. The real object of the diagram was to show how the difficult problem of the question of the traffic might be solved. In the roadways, provision would be made for vehicles of two speeds, quick and slow, and the rule of the road would be strictly kept to. The same provision was made on the pavements. There were two classes of people who used the streets, business people who get along as quickly as possible, and a second class who desired to walk slowly and look into the shop windows without being jostled and hurried. Provision was made for those two classes of people on the pavement in exactly the same way that provision was made for fast and slow traffic in the road.

Mr. MARK H. JUDGE was very glad the author had referred to the Strand improvements at some length, and finished his paper by expressing the hope that something would be done to induce the County Council to alter the line of frontage. He agreed with Mr. Blashill that some alteration should be made in the method of the disposal of land by the County Council in connection with the great improvements which were being made. There was evidently something wrong when land in that central situation, perhaps the principal thoroughfare of London, remained unsold and unoccupied for a long period, and it was not in the public interest that that should be so. Efforts ought to be made to cover that land with buildings in the quickest possible time, and he thought it would be a very great advantage if some steps were taken to force on the London County Council the suggestion made by the author.

Mr. BLASHILL said he did not take upon himself the responsibility of advising a change in the system, except if the Council desired to retain the kind of control Mr. Jackson and many others wished to have over the elevation.

The CHAIRMAN, in proposing a hearty vote of thanks to Mr. Jackson for his exceedingly able and interesting paper, thought Mr. Blashill's suggestion was a very pregnant one. He thought the suggestion made that land should be sold subject to the condition that the buildings erected were designed by a well-known architect would get over the difficulty quite easily. That system was adopted by the Duke of Westminster, with very satisfactory results.

The resolution of thanks being carried,

Mr. JACKSON, in reply, said there was a good deal he would like to say in reply to the gentlemen who had addressed the meeting, but as time was short he

must necessarily curtail his remarks. He thought the question of iron construction should be taken very seriously into consideration by architects. He was delighted to hear what Sir John Wolfe-Barry had said as to the necessity of abandoning the archæological way of looking at architecture, which not only on that but on many other grounds was the view architects were coming to themselves. The time had come when they must face the new conditions, and try and adapt their architecture to them, in the first place, considering that people in former days built buildings in a style which was very likely entirely unsuited to present necessities. With regard to what Sir John Wolfe-Barry said on the subject of abandoning the old styles, he had been much struck with the remark that they ought never to be afraid of showing the iron construction. He once had the privilege of going under Sir John's magnificent Tower Bridge when it was a naked structure of iron and steel, before it was disguised with the stone, and he was immensely struck by it. It seemed to him that was a new departure, not only in engineering but in architecture, and he believed he was right in saying that, among others, Sir John regretted when it was masked by the superstructure of stone which now disguised it, and gave it the fictitious appearance of its being supported by pillars of masonry, which would be utterly inadequate to the task they fulfilled. The iron structure should be visible, and should not be treated as if it were something to be ashamed of.

CANTOR LECTURES.

MUSICAL WIND INSTRUMENTS.

By D. J. Blaikley.

Lecture I.—Delivered November 28th, 1904.

Music stands in a unique position among the fine arts in this respect, that the conception of the artist obtains its realisation to a very large extent, by means of the mechanical arts and sciences, without which all music would necessarily be limited to the voice. In this characteristic it differs widely from poetry, which is absolutely independent of the knowledge of any designer, or the skill of any craftsman in dealing with the properties of natural bodies; it is more nearly allied with architecture, for as the architect has to consider how far the beauties of form and proportion which may present themselves to his mental vision are consistent with the properties of the materials at his disposal, so also has the musician to adapt his work to the instruments by means of which it is to be rendered, and to bear in mind not only their different qualities and mechanical peculiarities, but also the limitations they severally impose upon his executants. And it may be suggested that in proportion to the extent that the existence of these limitations is realised by the composer, so will he be able to produce work which will impress the hearer as being bound only by the laws of artistic beauty and fitness, and as being altogether unfettered by mechanical necessities.

This condition under which the musician labours has its counterpart or reflection in the work of the instrument maker, whose province it is to minimise to the utmost the impediments placed in the way of the artist by the mechanical nature of instruments: so that the æsthetic or psychical impression to be conveyed from the mind of the composer to the audience through the language of music, shall not be unduly weakened by difficulties in the way of the executant musicians. The ideal condition is that the player should be left free from all thought of mechanical work, or of forcing particular notes or intonations foreign to his instrument: the instrument should be in his hands so entirely responsive to every impression as to place him as nearly as possible in the position of the singer in the use of his vocal organ. Deliberate design to this end implies a knowledge both of the physical laws of sound and music, and of the physiological conditions ruling the technique of the fingering, handling, or blowing of an instrument, and such design is of comparatively recent date. The unsurpassed excellence of Stradivarius in his violin work, however, shows how much may be achieved by careful observation and experiment, ruled, perhaps, by a certain intuitive perception, approaching in character to an artistic faculty.

For ages, the art of musical instrument making was chiefly directed by the "rule of thumb," tempered by the application of the results of accumulated experience, and illuminated from time to time by the genius of men who, though ignorant of the physical principles underlying their work, yet had that artistic intuitive perception just referred to. When it is borne in mind that it is only since the date of Prof. Helmholtz's investigations that there has been any clear understanding of the nature of tone-quality, this state of things cannot be wondered at; but with the spread of the knowledge of acoustics, the art of musical instrument making is gradually becoming a branch of applied mechanics. It would be going much too far to say that all that is comprehended in the term "music" can be

explained by mathematics, for the principles of no fine art can be thus demonstrated, yet it is true that individual musical sounds come within the scope of measurement, and it is recognised that every musical instrument is as strictly subject to the laws of physical science as a chronometer or a locomotive.

In the year 1891 the late Mr. Hipkins delivered a course of Cantor lectures on "The Construction and Capabilities of Musical Instruments," and one of his three lectures was devoted to the "wind" section. The treatment adopted by Mr. Hipkins leaned rather to the musical use and position in the orchestra of the various instruments, than to the scientific or mechanical principles underlying their design, and as it is this latter side of the subject to which your attention will on this occasion be chiefly invited, any repetition of matter that was then so ably put before this Society, will I trust be borne with, as being led up to from a different point.

The three great groups under which all instruments are classed are the String, the Wind, and the Percussion, and it is the second of these which forms our subject. The Wind, however, for our purpose will be held to exclude all instruments such as the organ and the harmonium, which are played with a keyboard, and this limitation is customary. We have, therefore, to consider all such instruments as are blown directly from the player's lips, either with or without a vibrating tongue or reed. These, in combination, constitute the "wind band" in the orchestra, and practically the whole strength of the military band. They are commonly classed in two divisions as the "brass-wind" and the "wood-wind." terms which are recommended by custom rather than by accuracy: the further division of the "wood-wind" into reed instruments and flutes, introduces a better basis for classification, as these definitions neglect the material of which an instrument is made, and are based upon the means employed for tone-production. If to these two, "reeds" and "flutes," we add "cup-blown" or "lip-reed" in substitution for "brass," we have three definitions which are both accurate and practically convenient, and each one of these three groups will be the subject of the three subsequent lectures.

A complete survey of the history of wind instrument development lies outside the scope of these lectures, for our purpose is rather to deal with such instruments as they are, than as they have been, yet it may be of interest to pass in review the more important stages of progress.

The Table of classification here given shows the different families of wind instruments, with examples of each grouped under the three classes.

CLASSIFICATION OF WIND INSTRUMENTS.

Class.	Family.	Examples.
Brass or Lip-Reed.	Tubes of Fixed Length.	Trumpet, Bugle, French Horn.
	Length varied by Slide.	Trombone, Slide Trumpet.
	Length varied by Finger-holes or Keys.	Key-Bugle, Serpent, Ophicleide.
	Length varied by Valves.	Cornet, French Horn, Saxhorns of all kinds, Euphonium, Bombardon or Tuba.
Reed.	Enclosed Reeds.	Bag-pipe, Cromorne.
	Open or Mouth-Reeds (double).	Oboe, Bassoon, Cor Anglais.
	Open or Mouth-Reeds (single).	Clarinet, Saxophone.
Flute or Air-Reed.	Flûte-à-Bec.	Recorder, Flageolet.
	Flûte-à-Traversière.	Pandean Pipes, Cone Flute, Cylinder Flute.

As rudimentary types of these three classes I have here an Indian conch shell, kindly lent by Mr. Algernon Rose, a bag-pipe drone reed, and another short piece of reed stopped at one end. These may be compared respectively with a compensating four-valved euphonium or bass saxhorn, a modern clarinet, and a flute on Boehm's system.

There is good reason for the opinion that wind instruments, which in their present forms are of much more recent date than the string, are, in their primitive forms, older. The rudest string instrument would require for its construction more manual skill and mechanical aptitude than would be required to convert a conch shell or a hollow bone or tusk into an instrument which, although not musical in our sense of the word, would be useful for signalling either in war or in the chase. Particular illustrations of old instruments coming within historical times will be instanced as each group comes in review.

In the examination of wind instruments, one consideration comes very prominently before

us, and that is, the means they afford of obtaining some insight into the action of the human vocal organs. It is manifest that the voice proceeds from a wind instrument, highly complex, it is true, but approached more nearly by our comparatively simple wind instruments than by any other others, whether string or percussion. If I am right in this view, as I believe I am, our subject should be interesting not only to the specialist in wind instruments, but to the student of that most marvellous and perfect of all instruments, the human voice.

You may have noticed on the syllabus the statement that "every wind instrument is a vibrating column of air," but this definition requires some amplification. Expanding the definition, we may state that every wind instrument is a column of air of fixed or variable length and of definite proportions, capable of being put into longitudinal vibration of certain definite periods. To isolate such a column of air from the general mass it is necessary to avail ourselves of a tube of some rigid material, such as brass, silver, or wood, and it is this tube which, in common language, is called the instrument. The material of the tube, however, has but very small influence on either pitch or quality; the all-important factors are the exact form of the contained or isolated mass of air, and the means of exciting vibration. Here are three straight horns: two of them are of the bugle type, one being made of copper and the other of brown paper. You will notice that there is very little if any difference between them as regards their power and quality. The third horn is smaller in its general calibre, and for a considerable portion of its length is cylindrical instead of tapering. It is, in fact, a high-pitched trumpet, and you will notice the marked difference in tone-quality between it and the other two horns. Again, as an illustration of the effect of the means of exciting vibration, I will sound a few notes on the saxophone, a reed instrument; first by means of its proper reed and mouthpiece, and then by means of a trumpet mouthpiece, the general proportions of the instrument necessarily remaining exactly the same under each trial.

To put before you briefly the chief points influencing the results obtained in insrument making, I must ask you to follow me in considering the main facts in acoustics in so far as they concern our subject.

Acoustics may be defined as that branch of physical science which treats of vibratory motion as perceived by the sense of hearing. That a body giving forth sound is in a state of motion can in many cases be recognised by the senses of sight and touch, as when we see that a large string of a double bass is oscillating, or as when we touch a sounding-bell or drum-head. And we notice that anything which checks such motion, also checks sound: for instance, when we touch a wine-glass or tumbler at table which has been accidentally knocked; touching it with the finger, we stop its vibratory motion, and in so doing we stop the sound. That the air which is the medium of conveying sound from the vibrating body to the ear, is itself in vibration, is not generally self-evident, but when large and powerful pipes are sounded on the organ, we are sensible of the air in the neighbourhood of the instrument being in a state of tremor.

Before considering that variety of wave-motion evidenced by sound, the character of the motion of any particular particle under vibration must be understood, and this may be described as its recurrent motion about a defined position of rest. The most convenient illustration of this is the swinging of a common pendulum; for our purpose, let the amount of its swing be so small, that the curve of the path of its bob is not noticeable, and neglecting the wire or rod, we would have the bob travelling forwards and backwards over a short and apparently straight line. Let its position of rest be O and its total course of swing be from A to B:

O

A ——— A′ ——— ——— B′ ——— B

its motion from A to B, and back again to A, or from O to B, from B to A, and from A to O, constitutes a complete vibration, and the time occupied in the vibration is called the periodic time, or more briefly the period. The extent of the course from the position of rest O to the extreme position A or B is called the amplitude. The period is independent of the amplitude, for although the course of the bob should be only from A′ to B′ its time would be the same as if swinging from A to B.

This statement, that the period is independent of the amplitude, is subject to modification when the excursion from the position of equilibrium is very great, but it is true of such vibrations as we are concerned with in music, and anything like a *crescendo* or variation from *piano* to *forte*, would be impossible if this were not the case. Pitch is determined by the period or frequency of the vibrations, and

loudness by their amplitude, and if these two conditions were not independent of each other, music as we understand it would be almost impossible, for no variation in the intensity of a note could be produced, without an alteration of pitch.

Pitch and intensity in themselves, however, are not the only properties of musical sounds by which we distinguish one from the other. We easily recognise that sounds of the same pitch and intensity proceeding from different instruments vary greatly, and this variation we define as quality. This characteristic, quality, is due to departures from the simple condition of vibration illustrated by the swing of the pendulum. Such a vibration as that of the pendulum is known as simple harmonic, and is obtained from a large tuning-fork vibrating gently; it produces on the ear the effect of the vowel "oo" as in the word "food."

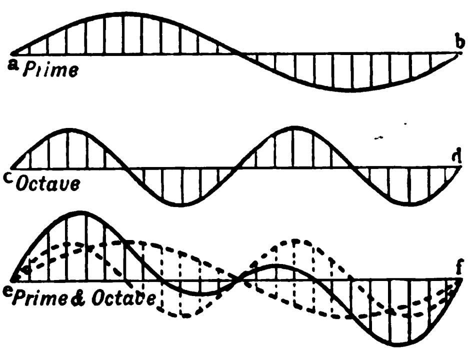
An illustration will assist us in understanding how two vibrations which are alike in period and in amplitude can differ in any way. Let a foot-race take place over a course say from starting-point A, to post B, and back again. It is evident that different runners may perform the race in the same time, and yet not keep together throughout the course. For one may keep an even pace throughout, another may improve a generally slow pace by occasional spurts, while a third may begin at a great speed and occasionally slacken, and a fourth may gradually improve his pace from beginning to end. Particles of air may behave just in the same manner in their courses or oscillations, and each such variety in the way vibrations otherwise similar are executed, affects the ear with the sensation of difference of tone-quality.

The diagram shows two simple wave-forms, *a—b* and *c—d*, corresponding to a prime and its octave, and one wave-form *e—f*, compounded of these two.

The amplitudes of the waves *a—b* and *c—d* are similar, and each of these curves is shown by dotted lines for comparison with the compound curve. It will be seen that the displacement from the straight line of any point in this compound curve (represented by the full line) is equal to the sum or difference of the displacements of similar points in the curves *a—b* and *c—d*.

We shall presently consider the transmission of sound from a vibrating body to the ear by aerial waves, but in the mean-time may note that the varieties of pitch and quality which produce such deep impressions upon our faculties, "from grave to gay, from lively to reverse," depend, as a matter of measurement, upon exceedingly small divisions, both of time and of space. Musical sounds vary in period from about $\frac{1}{40}$ to $\frac{1}{5000}$ part of a second: as the higher limit of pitch is approached, the distinctions of quality get weaker, but if we take a period of about $\frac{1}{500}$ of a second, or about the middle note of a soprano voice, we must acknowledge that at that pitch we can recognise innumerable differences of quality, and the only rational explanation we can give of these differences is that they depend upon the various ways in which a particle of air may travel over a minute space in a minute interval of time, which in the particular case named is $\frac{1}{500}$ part of a second.

Thus far, we have mentally isolated an individual particle, but in nature a single particle cannot have vibratory motion imparted to it



without influencing other particles in its neighbourhood, for all substances, whether solids, liquids, or gases, have their particles associated or linked together in equilibrium by certain forces, such as attraction and repulsion, and elasticity. The result of inter-action among particles thus associated is wave-motion, and it is by wave-motion in the air that the vibration excited in a solid or gaseous body reaches our ears.

We may consider what takes place when any given particle is displaced from its position of rest, say from left to right. The particle next to the displaced one has the equilibrium of elasticity on each side of it disturbed, and moves on to re-establish equilibrium, and so with each particle in succession.

By the time the particle first displaced has completed a vibration a series of particles has been put into motion, and another particle at a certain distance is ready to commence a

similar course. A wave-length is the distance between a particle in a given position, with motion in a given direction, and the next particle in a similar position and with motion in the same direction. Thus while an individual particle performs one complete vibration, the wave, consisting of a condensation and a rarefaction, advances by one wave-length. The impulse is passed on from particle to particle and the result is wave-motion.

Wave-motion may consist either of a rising and falling across the direction in which the waves travel, of which variety sea-waves, or the waves caused by wind under a carpet are examples; or of a swinging forwards and backwards in the direction of the wave's progress: this latter variety of wave-motion may be seen at times when a field full of corn is agitated by the wind, the swaying of the corn under the wind gives a better idea of vibrations in air than sea-waves give. A complete wave contains both a condensation or compression and a rarefaction or expansion; the air or other substance in the condensed portion of the wave occupies less than its natural space, and that in the rarefied portion occupies more.

The velocity of sound is the rate at which sound waves travel, and is independent of the period, the amplitude, and the form of the wave. It is dependent, however, upon the elasticity and density of the medium through which the wave passes, and in air, the only medium which we have to consider in these lectures, it is about 1,120 feet per second at 60° Fahrenheit, varying with the temperature in a manner which will be referred to later. In cylindrical tubes of the sizes used in wind instruments the velocity is very slightly less than this, but the difference is too little to require consideration in ordinary practical work. In this connection it may be interesting to note that wind instruments, which in their dimensions are determined by this velocity of sound, and which range in size from the piccolo flute to the contra-bass saxhorn, fall within limits of size and weight which can be conveniently handled, and such limits would be impracticable if the medium were hydrogen gas instead of air. For as the velocity of sound in hydrogen is nearly four times as great as in air, the little piccolo would have to be about a yard long, and the contra-bass would be about the length of a cricket-pitch.

The following Table shows the relationship between velocity, wave length, and frequency, or number of vibrations. The standard of pitch (c'' = 512 vibs.) generally used in scientific work has been chosen, but the method of constructing the Table is independent of the particular pitch.

Velocity of sound { 1,120 feet = / 13,440 inches. } per second at 60° Fahrenheit

Note.	No. of Vibrations.		Wave Length.	
	Absolute	Relative	Relative	Absolute
				Inches.
c'''	1,024	8	$\frac{1}{8}$	13·125
b♭''	896	7	$\frac{1}{7}$	15
g''	768	6	$\frac{1}{6}$	17·5
e''	640	5	$\frac{1}{5}$	21
c''	512	4	$\frac{1}{4}$	26·25
g'	384	3	$\frac{1}{3}$	35
c'	256	2	$\frac{1}{2}$	52·5
c	128	1	1	105

Now although the number of vibrations giving various notes, and the corresponding absolute wave lengths, are of great importance to those who have to design and make instruments, they are points which have no supreme importance in our general scheme of examination. The really important columns on the diagram are those with the heading "Relative," in which is to be seen the relationship between frequency and wave length for different notes in harmonic relationship, apart from any particular pitch, high or low.

It has been abundantly proved that the more perfect and satisfactory musical intervals depend upon simple ratios between the vibrational times or frequences of the notes producing the interval. The intervals given in the Table are those of the harmonic series, or the series of open notes on a brass instrument (*i.e.*, notes that can be produced on such an instrument without any contrivance for altering its length), such as a bugle. Comparing the numbers in the third column with the corresponding notes in the first, we notice the extreme numerical simplicity ruling the most important musical intervals. For instance, in the common chord *c—e—g*, for every four vibrations of *c* there are five of *e* and six of *g*. [These chords were given on tuning forks.] Sonorous vibrations are mainly of two classes, transverse and longitudinal.

When a stretched string, such as a violin string, is thrown into vibration, it is usually by a displacement which causes oscillation *across* the direction of its length; this is an instance of transverse vibration. But by lightly drawing a resined rag *along* such a string or along a wooden rod, such as is fixed in this vice, it can be thrown into longitudinal vibration.

Experiment.—Rod in transverse and in longitudinal vibration.

Experiment.—Weighted steel coiled spring illustrating transverse and longitudinal vibrations.

We can throw a gaseous rod or column of air into longitudinal vibration, as illustrated by the wooden rod and the spring, and confining our attention in the first place to cylindrical tubes, we must endeavour to arrive at a clear conception of the distinction betwen progressive waves and stationary waves.

The wave, which on this revolving disc appears to issue from the centre and travel to the circumference, represents a sound-wave, as it travels through free or unconfined air, or through a tube of indefinite length: every particle of air through which it travels takes up in turn exactly the same motion, making allowance only for the gradual enfeeblement of the wave. By such progressive waves our ears receive the sensation of sound from musical instruments, but the waves set up in the instruments themselves are of the class known as stationary waves. This variety of wave can be illustrated by means of another disc.

When a pulse of condensation as from a tuning-fork, passes along a tube with a closed end, it is there reflected, and when the period of such a double passage agrees with the half-period of the fork, a powerful resonance is the result. During the other half-period of the fork, a pulse of rarefaction is similarly travelling over the length of the tube twice. [Experiments were here shown to illustrate these points.]

In a tube closed at one end, a pulse has to travel over the length of the tube four times to complete its cycle, that is, to and fro as a pulse of condensation, and to and fro as a pulse of rarefaction. The lowest note to which such a tube can give a perfect resonance has therefore a wave-length four times the length of the tube.

A tube open at both ends, behaves, when sounding its lowest note, as if it were two closed tubes such as we have been experimenting with, placed with their closed ends together.

As the waves from each end travel in opposite directions, they meet in the centre, and are reflected, just as they would be from a solid surface. In neither case can the oscillation of the air-particles pass this plane of reflection, and the consequence is that at this reflecting surface the air is at rest, but its density varies between a state of maximum compression and maximum rarefaction.

This action is more easily traced when a tube is taken of sufficient length to comprise two or more nodes; the nodes, or surfaces, where the air is at rest, then alternate is position with points or surfaces called anti-nodes, or loops, where it is in a state of maximum motion.

The condition of any node varies with the motion of the air on each side of it, which is in contrary directions, and at the loops, midway between the nodes, the density of the air remains unchanged. The distance between two adjacent nodes or loops is a ventral segment, and the distance between two nodes which are in the same condition is the wave length, which, for any given note is equal to the velocity of sound divided by the number of vibrations producing that note.

It is because a node is a point of no motion, but of reflection, that a tube may be closed at such a point without influencing its note, but at no other point, and that only those notes whose waves have a node in the position of the closed end can be sounded on a closed tube.

A moment's consideration will make it clear that when air in a tube, with one or both ends open, vibrates, there is an alternate influx and efflux of air, for the air required to increase the density at the node can only be supplied from the outer air, and conversely, the rarefaction can take place only through air passing from the tube into the outer air.

In these experiments we have excited vibration in the tubes or air-columns by forks, but in practical instruments, which are rarely cylindrical tubes, other means are employed, and these means form the basis of the classification adopted. In the next lecture we will consider the results obtained by the various modifications of the cylindrical form of tube, and by the use of the lips in place of forks to excite vibration, tracing the development from the simple shell or horn to the modern brass instrument.

ST. LOUIS EXHIBITION.

The following retrospect of the exhibition just closed is from the special correspondent of *The Times*:—

It has long been evident that, looked at from a financial point of view, as well as from that of both attendance and influence, this exhibition, perhaps the last of its kind—was certain to be a comparative failure. It is not difficult to account for this. In the first place, the people of St. Louis are not active, enterprising, money-spending people like those of Chicago. In like manner, the surrounding population does not compare in these respects with that of the city by the Lake. As an effect of this the purely local interest has been slight from the opening days. It soon became apparent that there was to be a reasonable attendance from States comparatively distant, but a light one from St. Louis itself. It must not be overlooked that this verdict is modified by the use of the word comparative, because even in the remainder of the country the interest has not been large. From the beginning the exhibition has attracted only the slightest attention in the Press, and it would probably be safe to say that three times as much matter of a serious character has been published about the exhibition in the Press of London as in New York and Philadelphia, the two combined about equalling the population of London. In fact, it has been surprising to find how little attention has been devoted to what, in all intents and purposes, was a Government project. This being the case, there has been little interest in the awards. This is, perhaps, accounted for by the fact that, so far as domestic industries are concerned, a large number of the houses connected with them are so new that they know nothing of the old struggle for what were called industrial honours. Perhaps the tendency to combination which removes competition also removes the incentive for seeking the kind of recognition hitherto deemed of importance and value.

It was estimated by the enthusiastic organisers that the exhibition would attract not fewer than 30 million visitors, and in many quarters the predictions placed it at a much larger figure. The total attendance at Chicago amounted to about 28 millions, of which the usual proportion of three-fourths was paid in admissions, the remainder being what is known in the theatrical profession as paper. So far as can now be determined, the attendance at St. Louis has amounted to a scant 14 millions, of which not more than 10 millions will be paid in money at the gates—the proportions of free admissions being somewhat larger, according to present indications, than at either Philadelphia or Chicago.

But perhaps the strongest influence that has been at work is the conscious recognition of the fact that great exhibitions have been overdone, and that they no longer have a direct, or even an indirect, value compared with those held in earlier days. Then, too, there is a very strong feeling in the minds of many people that they are used to push the fortunes of ambitious men, otherwise uninteresting or unsuccessful, and that, too, at the expense of the general Government, the State, or a city, or all combined. This is true, in spite of the fact that some of the men connected with the organisation and management at St. Louis have done a great deal of work under many difficulties, and have had only the slightest real recognition at home, and, in many cases, have been compelled to meet a great deal of criticism that was wholly unjust. Another element that has entered into account is the fact that the occasion itself was not so uncommon or so important as to attract general attention. That the Louisiana purchase was a very important event in the history of the United States is not open to question, but as it merely marked the continuation of a policy which began with the earliest days of American history, and as it was only the largest of many like acquisitions, the imagination of the country has not been excited by it as it was by the centennial of the Declaration of Independence and by the fourth centennial of the discovery of America.

When all these forces are taken into account, there is no occasion for surprise if the end of the present exhibition is welcomed by more people than its opening, and by none more cordially than by those who had been at the head of the movement. It would be absolutely impossible for any one who had not known the inside to appreciate the pettiness, the jealousies, or the open opposition that its leading men, especially its president, have had to meet and overcome. In many respects, it has been a conspicuous failure, largely because a great deal more was undertaken than ought to have been and because the schemes grew upon its organisers as new demands were made for money and upon their own capacity for management.

It is probable that this is the last attempt that will be made in this country to celebrate any great act by a universal exhibition. I have had occasion, from time to time, to outline the difficulties and to set forth the great amount of money necessary for carrying out such a scheme. It is not likely that any contributors will ever come forward again to furnish a like sum of money for this kind of display.

COLONIAL PRODUCE.

The exhibition of Colonial produce at the Royal Horticultural Hall should be of use to the colonies exhibiting. Everything that tends to make the British consumer better acquainted with Colonial products is welcome. The idea of the Old Home Society holding exhibitions of Colonial produce has only been rendered possible for the first time this year by the completion of the society's new Centennial Hall, in Vincent-square, Westminster. In the present exhibition, the Dominion, and some of the principal West India islands, are the chief exhibitors. The Dominion exhibits were mostly apples, and some of them, those

especially from British Columbia, are very fine, and in excellent condition, notwithstanding a journey of 6,000 miles, half of it by land. In flavour, size, appearance, and market qualities they leave nothing to be desired. The exhibits from the West Indies were much more varied. There has been a great development in the fruit trade between these islands and the United Kingdom since the Government subsidised the Elder Dempster line running to Jamaica. Under its new management, and influenced no doubt by the Jamaica competition, the Royal Mail Steamship Company is offering facilities to fruit shippers, and the shipments of bananas from Barbados and Trinidad are already considerable. But it is slow work, even with bananas, largely owing to the fault of the growers. They are unbusinesslike, and careless of the market. Large as are the shipment of bananas from Jamaica, they would be much larger if the bananas shipped were of the right kind. But the Jamaica planters have been accustomed to grow a particular banana for the American market, a long coarse banana known as the *Gros Michel*, and it is this fruit they send to England although it does not suit the English taste, or fetch more than half the price of the dwarf banana (*Musa Cavendishii*) that comes from Barbados and Dominica. Then again the Barbados planter, though keen enough in some ways, is slipshod. He will write over for a quotation, and if it does not suit him—and he is not easily satisfied—nothing more will be heard of him. There are not many plantains at the exhibition, which seems a pity. It would be a real boon to the poor if plantains were as plentiful and cheap on this side as bananas. They are an excellent and sustaining food, and when well-cooked, very palatable. It was interesting to note among the Barbados exhibits, some very fine cotton of the Sea Island variety. There are now 1,600 acres of this cotton in cultivation in the island, and the growth is rapidly extending. A very fine spadix of palm nuts is exhibited by Trinidad and has been secured by Sir W. Thistleton-Dyer for the museum at Kew. Trinidad is beginning to develop the palm oil industry and is already exporting. Dominica, which a few years ago was perhaps the most backward of the larger West India islands, is now making rapid headway. Cacao has become an important article of export, and large plantations have been successfully established in the highlands of the interior. Rubber trees grow luxuriantly, and there is a considerable export trade in lime juice, and limes in all forms. The island owes much to its present energetic administrator, Mr. Hesketh-Bell, who is inducing many young farmers to try their fortune in Dominica. It offers great possibilities to young men conversant with farm work, possessed of a modest capital, not afraid to work, and of cleanly life. There was a fine show of shaddocks at one of the stalls, but there is never likely to be much of a demand for them in this country. They are too large and coarse, but eaten West Indian fashion, with the core cut out and port wine poured in and allowed to soak for a day, they are inviting. How is it, by the way, that no enterprising firm sells shaddock bitters? Orange bitters have a large sale, and those who have tried both think shaddock the better.

At present there are considerable difficulties in the way of West Indian fruits, other than bananas, being sold largely in this country. The main difficulty is in the unwillingness of the retailer to handle them. Until the public are better acquainted with their merits, he runs a great risk of the fruit rotting before it is sold, and the only way to make the public more appreciative would seem to be the establishment here and there, in favourable positions, of shops making a specialty of these fruits and inducing the public to test them. These shops would have to be subsidised for a time, and it ought not to be very difficult to induce exporters and carriers, that is to say planters and steamship companies, to provide a fund for this purpose. There is a difficulty in the way of the Royal Mail Steamship Company being a contributor to such a fund since under its charter it is not allowed to engage in any other business than that of carriers, but there are ways by which this difficulty could be got over. It is a curious fact that, whilst the charter of the Royal Mail Steamship Company is so rigid in vetoing any business but the one for which the charter was granted that the company may not erect or work a West Indian hotel, the Government contract with Sir Alfred Jones's line not only permits but encourages the company to go into hotel management. But then the charter was granted in 1838, and the contract was signed only a few years ago.

CORRESPONDENCE.

THE PATENT LAWS.

I much regret that illness prevented me from being present at the reading of my paper and the subsequent discussion.

I was glad to note that the speakers were all, more or less, in agreement with me on the main arguments of my paper, and I have therefore much to say in reply to the several points raised. I may state, that in the original draft of my paper, I had referred to all these points, and a great many more, but the paper became of an impossible length, and I had therefore reluctantly to cut out more than half the subject matter and to confine myself to the main arguments which I desired to bring forward, *i.e.*, the fallacy of the German and United States' system of examination, the advantages of the system about to be introduced here, and the necessity of making that system as perfect as possible.

With regard to the Chairman's remarks, I have to say that I had pointed out in my original draft that when I spoke of meritorious inventors deserving

recognition by the State, I referred to those who, besides making their invention, also devoted their energies and capital to carrying the same into practice, as I quite recognise that there is as much merit in this as in making the invention, and I have, in fact, said as much in my paper.

The inventor who merely puts more or less crude ideas into a patent specification, and leaves entirely to others the task of putting them into practical shape, is, to my mind, hardly entitled to patent protection, because, as I have pointed out in my paper of 1865, patent protection was not instituted so much as a reward for the ingenuity displayed in making an invention, but rather to act as an inducement to inventors to devote their energies to and their money in carrying the same into practice.

In this connection I may say that, in my opinion, the Swiss law, which requires proof of the invention being carried out before granting the full patent, is sound enough in theory, but, unfortunately, as is usually the case, the carrying out of this law has been surrounded with so much red tape as to be in very many cases objectionable in its operation. With regard to Messrs. Justice and Hardingham's remarks, I may say that in my original draft I had fully pointed out the imperfect nature of the examination about to be carried out by the Patent Office, but, at the same time I showed that at anyrate the Patent Office was going to do for a nominal charge what at the present time it cost many inventors a very considerable sum to have properly performed, and that as practically most inventions of any importance patented in Germany and the United States were also patented in England, one search would cover considerably more than merely the inventions made in this country.

As this question as to what constitutes a prior publication of an invention is a purely arbitrary one, I see no reason why the Government, while deciding that inventions described in patents more than fifty years old, and in abandoned provisional specifications, should not be considered prior publications, might not have gone a step further, and enacted that only inventions described in English patent specifications should be considered as anticipating publications.

As practically no invention is made in this country without being patented, such a law would entail no hardships on British inventors.

With reference to Sir Lloyd Wise's letter, if he reads my paper he will see that I quite agree with him as to his objection to the rule enabling the Comptroller-General to cite anticipating patents in the specifications, but I do not agree with his apparent interpretation of the rules to the effect that the objectionable notice is to be inserted by the Comptroller whether the applicant decides to refer to the anticipating patent in his specification, or not to do so.

Section 6 of the Act of 1902, states that the Comptroller "shall after hearing the applicant, *and unless the objection be removed by the specification*, to the satisfaction of the Comptroller, determine whether a reference to any, and if so, what prior specifications ought to be made in the specification.

Surely the "objection" would be "removed" by the applicant "amending his specification" in referring to the prior patent in question, and pointing out where his invention differed from the same; and in this respect the applicant would have the safeguard of an appeal to the law officer, as provided in Section 7.

The Comptroller has a large and difficult task before him, and I do not think he should render it more difficult by a premature wholesale condemnation of the new rules, but should rather wait to see how they are carried out before complaining.

The Patent Office has shown good sense and consideration heretofore in its dealings with patentees, and I think we can fairly trust the Comptroller to carry out the new law with due consideration for the interests of inventors. Mr. Guttman spoke somewhat disparagingly at the meeting as to the qualifications of the examiners of our Patent Office as compared with those of the German Patent Office, but I must say that, as far as my experience goes, the greater efficiency lies quite the other way. I have frequently had to contrast the unreasonable and frequently incorrect arguments and requirements of the German and United States examiners with the generally reasonable and pertinent objections raised by the examiners of our Patent Office, and, however superior the previous training of the German officials may have been, I do not find that they are equal to those of our Patent Office in the matter of common sense views.

THE BRITISH CANALS PROBLEM.

The contentions put forward in Mr. Lee's letter on this subject in last week's *Journal*, do not by any means dispose of the objections against the scheme of local control. Mr. Lee argues that the railway companies could crush private enterprise by reducing railway rates, and that from the same cause the capital expended on developing a waterway might be deprived of all return. One is entitled to ask in what respect the local authorities would fare better. I contend that as far as the financial results are concerned, no distinction can be recognised between one and the other, and as long as the railway companies are free to fix what rates they choose (and I presume that no legislative attempt will ever be made to interfere with that freedom) the local authorities would run precisely the same risks as the private owner. In other words, Mr. Lee's contentions on this point exactly confirm and strengthen my arguments against the expenditure of enormous sums of public money in a direction where the probability of any return is so largely a matter of conjecture. It is perfectly obvious that the

canals will always have to reckon with the competition of the railway, but it is certainly not so obvious how that competition can be lessened by substituting municipal in place of private ownership. The local authorities themselves have, I believe, taken this view of the question, and shown unmistakable objections to rush in where private enterprise fears to tread. I think, in fact, I am safe in asserting that neither Parliament nor the municipal authorities will have anything to do with a scheme of canal development which carries with it a certainty of vast unprofitable expenditure. Mr. Lee thinks it unreasonable to point to an increase of debts without considering any increase in the value of the assets, and cites the growth of railway debt between the years 1872 and 1892, but I fail to see how this bears upon the question. In the first place the railway constitutes our principal means of inland transport and locomotion, and in increasing their assets the railway companies have simply kept pace with the growth of population and public requirements. With this increase of debt there has been a commensurate increase in traffic receipts. Had there been no such result, then assuredly the railway companies would be pursuing a policy which would speedily land them and the nation in bankruptcy. The canals are in an utterly different position to the railways. They constitute a subsidiary means of transport, and one not likely to increase in favour with the industrial community. The railway and the road will be keener competitors in the future than ever before, and to what extent, traffic will be diverted from them to the canals, or exisfing traffic on the latter increased, no one has been bold enough to estimate. I think, therefore, that it is perfectly reasonable to emphasise the point that heavy expenditure on canal development is likely to be unproductive. I scarcely think the ratepayer would be satisfied with the knowledge that though his rates might be increased he could console himself with an increase in the value of unproductive municipal assets. I am glad that some local uthorities, at least, have shown no favour to such slipshod finance.

There is another aspect of the canal problem to which I may briefly refer. Mainly through the suicidal policy of the canal companies in the forties of maintaining high rates, the railway companies were able to acquire, between the years 1845 and 1848, 1,000 miles of canals, so adroitly chosen that at the present time they constitute the key of the situation. Assuming that the local authorities acquired any particular waterway, it would probably be necessary to buy from the railway companies other canals controlling through-navigation, in order to prevent the imposition of restrictive or prohibitive rates. Here we have an appalling prospect of unlimited expenditure, and yet, according to the scheme of local control, it would be a matter of necessity for the local authorities to embark on that expenditure in order to make the fullest use of the canals they might acquire. I think I am justified in saying that this would be a disastrous course to adopt. Fortunately, it is unnecessary, and, judging from the attitude of certain municipalities, one which it is extremely improbable will be followed. In the interests of canal development it is a matter of regret that the promoters of the scheme do not recognise its impracticability, and address their energies to something which has a chance of being accomplished. The first object to be aimed at is the abolition of high tolls on the railway-owned canals and the removal of all obstacles to their legitimate use. When this primary evil has been removed, the most formidable impediment to canal development will disappear. Others will remain, but none that cannot be remedied by private enterprise. One thing is certain. Our waterways are never likely to regain a tithe of the importance which belonged to them 70 years ago, when dividends of from 30 to 80 per cent. were not uncommon, but their utility can be increased if those who are interested in the improvement of their condition will recognise the limitations of canal transport, and promote no schemes which entail either nationalisation or municipalisation.

GENERAL NOTES.

Martinique.—Figures supplied by Mr. Consul Meagher in his report on the trade of Martinique (just issued) afford striking proof of how British shipping finds its way to foreign ports doing only a very small trade with the United Kingdom. Thus whilst the total value of imports into Martinique in 1903 amounted to £815,582, of which no less then £743,867 came from France, French colonies, and the United States, and the exports amounted to £604,162, of which £563,329 went to the same countries, the tonnage of British shipping entered in the port of Martinique in the same year was greater than that of any other country not excepting France, and the same remark applies to vessels cleared. Only six American vessels, aggregating 4,210 tons, were entered, although America's imports (£260,706) amounted in value to nearly one-third of the whole.

MEETINGS FOR THE ENSUING WEEK.

Royal Institution, Albemarle-street, W., 3 p.m. (Juvenile Lectures.) Mr. Henry Cunynghame, C.B., "Ancient and Modern Methods of Measuring Time."

Tuesday, Dec. 27. Ancient Sundials and Clocks.

Thursday, Dec. 29. The Discoveries of Galileo.

Saturday, Dec. 31. The Pendulum and Balance Wheel.

Journal of the Society of Arts.

No. 2,719. VOL. LIII.

FRIDAY, DECEMBER 30, 1904.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

NOTICES.

NEXT WEEK.

WEDNESDAY, JANUARY 4, 5 p.m. (Juvenile Lectures.) CARMICHAEL THOMAS, "The Production of an Illustrated Newspaper." (Lecture I.)

Further details of the Society's meetings will be found at the end of this number.

JUVENILE LECTURES.

The usual short course of lectures adapted for a juvenile audience will be delivered on Wednesday afternoons, January 4th and 11th, at 5 o'clock, by Mr. CARMICHAEL THOMAS, Treasurer of the Society, on "The Production of an Illustrated Newspaper."

Each member is entitled to a ticket admitting two children and an adult.

A sufficient number of tickets to fill the room will be issued to members in the order in which applications are received.

Nearly all the tickets have now been issued, and members are therefore requested to apply for them at once.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

MUSICAL WIND INSTRUMENTS.

By D. J. BLAIKLEY.

Lecture II.—Delivered December 5th, 1904.

Before proceeding to the specific subject for this evening's lecture, *i.e.*, Brass Instruments, I must ask you to be so good as to follow me in a brief recapitulation of some of the points introduced on Monday last. We then considered the vibration of any particle as its oscillation about a position of rest, and wave motion as being the transference of such vibration from particle to particle. As it is of importance, in view of other illustrations coming before us, to have a clear idea of the distinction between the vibration of a particle and the advance of a wave, I will put in motion again the disc illustrating the advance of a wave of sound, and also the disc illustrating a stationary wave.

[Experiments with disc advancing wave and stationary wave.]

It was further stated that an open tube had for its proper tones, or tones to which it could naturally respond when excited by tuning-forks or other means, the notes of the harmonic scale, or those whose ratios of vibrations are represented by the simple arithmetical progression 1, 2, 3, 4 ...... 8, &c., &c. This can be illustrated by a tube I have here.

[Experiment with open tube excited by forks sounding c, c′, g′, c″.]

It was also stated that a cylindrical tube stopped at one end could give only those notes of the harmonic series that are represented by the odd numbers, 1, 3, 5, 7, &c., or c, g′ e″, &c.

[Experiment with closed tube excited by forks.]

There is one other simple form which has its natural tones in the same order as the open cylindrical tube, or other tube of equal section throughout. This form is the cone.

[Experiment with paper cone and forks.]

Before passing on to the examination of the actual forms of brass instruments, this consideration will naturally present itself to your minds; can the action of the lips be held to be the same as regards pitch, as the excitation of the air in a tube by vibrating forks?

I have here a small hunting-horn, giving the note c 512 vibs. when blown by the lips in the usual way. If instead of blowing the instrument, we excite vibration by holding a vibrating tuning fork of this pitch over its mouth, we notice that there is little or no resonance so long as the tube is open, but directly it is closed by the rim of the mouth-piece touching the sur-

face of water in a glass, the note of the fork, which agrees with that of the tube when closed, is distinctly heard.

From this experiment, we must understand that a brass instrument is a tube closed at one end, as is indeed, pretty self-evident, but it is also manifest that it is not a cone complete to its apex. There are certain wind instruments, such as the oboe and the bassoon, in which this is practically the condition, but the closed end of a brass instrument must have sufficient width for the action of the lips.

By cutting off a portion of the cone, we can get room for the action of the lips; this cone can be divided at the position of one of the nodes of c″, its fourth proper tone. That note can therefore be sounded, but no other of the original harmonic series of the cone; the other notes possible are inharmonic, the c″ being the third of the series:—

1st. Divided cone gives c sharp, e flat, c″.

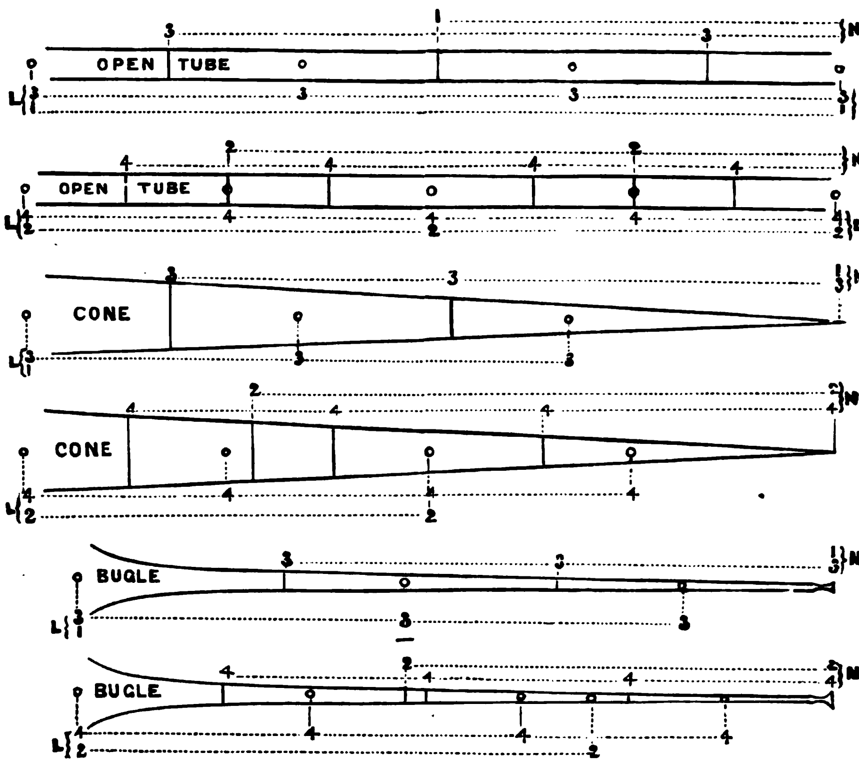
2nd. Another tube c′, c sharp$_1$″.

3rd. Another tube c′, e″.

[Experiments with truncated cones.]

From these experiments, it may be seen that by using portions of cones of different proportions with their small ends closed, it is possible to get different series of intervals, varying between those of an open and those of a closed tube; that is, the first interval varying between an octave and a twelfth.

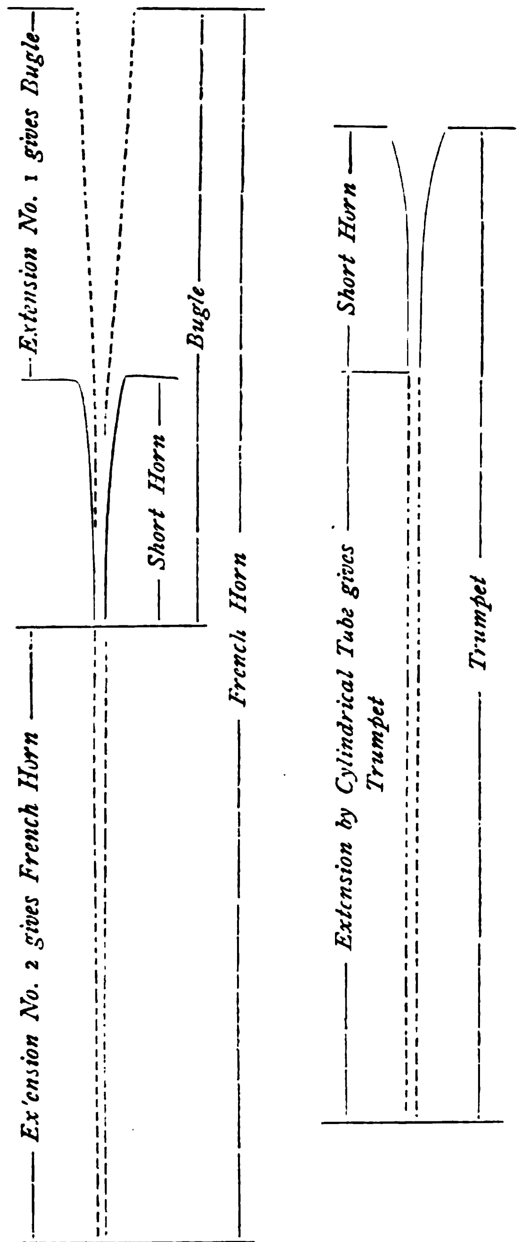
The second example given, c′, c″ sharp, does not appear to be far removed from the required condition: but as cylindrical tubing must necessarily be added to such a cone in practice, either by means of valves or slides, we may try the effect of such an addition. Flattening the cone a fourth from c′ to g by adding cylindrical tube, we obtain the notes g, e′, d″ in



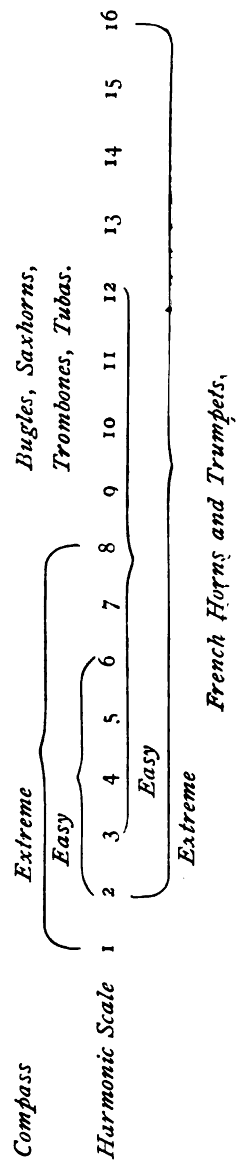
place of the g, g′, d″ required, or notes in the ratios 1, $1\frac{2}{3}$, 3, in place of 1, 2, 3, the second interval being actually greater than the first. Other modifications might be shown, but the result of them all is that the sudden change of form from a right cone to cylindrical tubing cannot give the desired result, which is a tube of such form, that though it is closed at one end, its proper tones shall be those of a cylindrical tube open at both ends.

Seeing that a bugle, or other such instrument, although it has a considerable diameter at the mouthpiece, may nevertheless be in tune, it appears that its various nodal surfaces cannot be in the same positions as those on

the cone. On the diagram is represented a bugle of the same pitch as the open tube and the cone, with the positions of the nodes and loops of the first four harmonic notes. Comparing the positions of the nodes and loops for any given note, say No. 4, it will be seen that on the bugle the length from mouthpiece to node is more nearly equal to that between similar nodes on cylindrical tubing than to that between similar nodes on the cone, but from node to mouth or bell-end is greater than on the cone, the bugle opening more rapidly. Thus, then, by altering the proportions of the different semi-ventral segments of which a brass instrument may be conceived to be built up, the positions of the nodes may be so arranged that there is a node for every note at the mouthpiece as required, and according to the degree of accuracy attained in this, will the instrument be more or less accurately in tune.



DEVELOPMENT OF WIND INSTRUMENTS FROM THE NATURAL HORN.



We have on the table a series of four bugles, one undivided, giving c as its prime, and three divided into segments for the c′, g′, and c″; and four cylindrical tubes similarly treated. These correspond with the bugle and open tube on the diagram.

From any segment we can obtain the note proper to that particular division.

[The notes proper to each segment, and to the various groupings of the segments were here given by blowing.]

As the nodes are planes of reflection, it is possible to put diaphragms in the nodal positions, corresponding to a particular note, without preventing the speech of that note, but a diaphragm thus placed will effectually block out vibrations of the periods necessary for other notes. [Experimentally shown.]

With these fundamental points before us, we are in a position to understand the scientific facts underlying the history and practice of wind-instrument manufacture.

The brass wind may very well be compared with an ox-horn as a standard of reference. Such a horn is here: with the exception of the cupped mouthpiece, it may be regarded as a natural object, and is therefore almost as simple an instrument as the large shell. By means of a slide on the screen, the relationship of modern instruments to it can be traced out.

The short natural horn being taken as the rudimentary type, its extension in length, without alteration of calibration, results in the bugle; further extension, with reducing diameter at the small end, gives the French horn. These two, the bugle and the French horn, may stand as representative of all conical instruments, as the modern saxhorns and tubas are, speaking broadly, enlarged bugles.

When cylindrical tubing, however, is added to the short horn, the type of instrument obtained is the trumpet, which, with some alteration of calibre and length, becomes the trombone.

Before describing in detail the means successively used for completing the chromatic scale from the notes of the harmonic series, some reference may be made to the chief causes influencing tone-quality. [Three brass instruments of different tone-quality, the euphonium, the trombone, and the French horn, were sounded.]

The different tone-qualities of these instruments depends chiefly upon the relative strength of the upper partials or harmonics in comparison with the prime, and this variation in strength is mainly due to three factors, viz.:—

1st. The general form of the instrument in its calibration.

2nd. The extent of the bell flange, and

3rd. The exact form of the mouthpiece.

1st. *General Form.*—An open, spreading bore favours the strength of the lower partials, and this results in a bold and broad tone of the bugle type. When the calibration is small compared with the length of the instrument, as on the French horn, the tone becomes more tender and refined, but lacks virility, and perhaps dignity.

Again, keeping the general diameter small, but making a large proportion of the tubing cylindrical, we obtain the trumpet with its brilliancy, and the trombone with its great range of expression from martial ardour to the most solemn dignity. These results depend in some degree upon the character of the reflection of the wave at the open end of the tube. For the reflection to approach completeness, the diameter must be small in comparison to the wave length.

2nd. *Extent of Bell Flange.*—When the bell-mouth is wide, either from the general calibre, as on the bombardon, or by an extension of the flange, as on the French horn, the diameter becomes considerable with respect to the wave-length of the upper partials, and these become very much damped.

[*Experiment.*—A bell with wide flange was substituted for the ordinary bell-mouth on the bugle, causing a marked modification of the tone-quality.]

3rd. *Form of Mouthpiece.*—The cups of the mouthpieces of brass instruments vary from an almost hemispherical form to that of a deep conical funnel. The shallow or hemispherical cup is used with trumpets and trombones, and tends to strengthen the upper partial tones. The funnel form belongs to the French horn, and the intermediate degrees of depth are used for the various kinds of bugles, cornets, saxhorns, and tubas.

It is evident that the notes proper to the lower part of the harmonic scale, from Nos. 1 to 8, do not suffice for the diatonic scale, and still less for the chromatic, but between the 8th and the 16th harmonics lie many notes required for the diatonic scale. If we lower the pitch of an instrument an octave by making it longer, the note originally the 4th becomes the 8th and the 8th becomes the 16th. By the mere lengthening of an instrument, therefore,

its musical usefulness, so to speak, is increased.

Side or Finger-holes.—One means of obtaining a scale on a lip-blown instrument, which has died out only in our own time, is the use of side or finger-holes. By boring a hole in the side of an instrument its length is virtually altered, and six such holes, controlled by six fingers, give, with the original full length of the instrument, the seven tones of the diatonic scale, capable of being repeated in the octave, by over-blowing. These instruments were known as "zincken" in German, or "cornetti" in Italian. The weak point in the larger of these instruments (the serpents) was their bad intonation, through the necessity or supposed necessity of considering the span of the fingers. With the general adoption of key-work this necessity disappeared, and the result was that the bass members of the family have only become obsolete in our own day. The serpent, which was a conical tube sounding the 8 foot c and its harmonics, was originally made with finger-holes only, and these were of necessity small in diameter compared with the calibre of the tube. The instrument for convenience of handling was made of a double S form

and by degrees, holes covered by padded keys took the place of, and also supplemented the finger-holes. The basson Russe, or bass horn, and the ophicleide, each of which has had its own day, are merely modifications of the serpent, and introduce no new principle. The key, or Kent bugle, is the treble instrument of this family, and before the introduction of the piston-valve, was an important feature in a military band.

In all these instruments, pierced with side-holes covered either with the fingers, or by keys, a chromatic, or in some cases merely a diatonic scale was obtained through shortening the tube by successive steps. In those we now have to consider, the opposite principle, that of increasing the normal length by successive steps, is brought into play.

The oldest and in some respects the best method of altering the length with sufficient promptness for musical purposes, is the double telescopic slide fitted to the cylindrical portion of the instrument. Ths slide enables the player to flatten his instrument to the extent of seven semitones as from C to F sharp. Each of these seven "positions" is the basis of a separate harmonic series, and by this means a complete chromatic scale can be built, from the second tones of the series upwards. The principle of such a slide is excellent, but its application is limited to instruments with a large proportion of cylindrical tubing, and therefore of a certain tone quality. Instruments of the conical or bugle type are excluded, and it is this large family to which the modern valve system is peculiarly applicable. The valve, whether of the "piston" or "rotary cylinder" type is so arranged that on its depression in the one case, or quarter revolution in the other, a certain extra loop of tubing is brought into the effective length of the instruments. In a three-valve set, the extra lengths thus introduced are respectively, one, two, and three semitones, and by using the valves in combination, the series of added lengths can be extended to agree with the seven "positions" on the slide trombone. To the larger bass instruments, a fourth valve, giving an interval of fourth, as from C to G, is very generally added. When valves are used in combination, however, the note is usually slightly and, in certain cases, considerably sharp, and the reason for this can be easily understood. If a valve is adjusted to flatten an instrument a third, as from C to A, a second valve adapted to alter the pitch a tone, from C to B flat, cannot also give a true tone, when the instrument has already been lengthened or flattened from C to A by the depression of the first-named valve, for the added length for a given interval should always be in a certain ratio to the lengt of tube already in use. This difficulty has long been known, and many arrangements have been designed to overcome it; one system of valve action with this object in view was designed by me about thirty years ago for Messrs. Boosey and Co., and is now very generally known as the compensating piston.

The total range of compass in brass instruments is about one octave greater than the whole range of the human voice, and this extra octave lies below the bass voice. A fairly good cornet player can give the high A or B flat of the soprano voice, and an exceptional player can go two or three tones higher, just as the exceptional singer can do, while a bass tuba player can take the E flat or D an octave lower than the lowest notes of the bass voice.

By means of a pressure-gauge, first used, I believe, by the late Dr. W. H. Stone, it is possible to measure the pressure in the lungs when blowing instruments, and although there

is no particular interest in observing the maximum limit, an interesting point may be noted as regards the lower limit. For any given series of notes, this appears to be directly proportional to their vibrational frequencies, and for a note of any particular pitch, to be independent of the size of the instrument.

[These points were shown by experiment.]

The lecture was illustrated by lantern slides of plates from the following works:—Sebastian Virdung, Musica, Basel, 1511; Michael Praetorious, Syntagma, Wolfenbüttel, 1618; Georges Kastner, Manual Général de Musique Militaire, Paris, 1848.

MEMORIAL TABLETS.

It is thought that it might be interesting for the members to have an opportunity of comparing the memorial tablets adopted by the Society of Arts, and by the London County Council, so a representation of the two tablets is given herewith.

The London County Council tablet is one put up by the Council to Sir Robert Peel, at 4, Whitehall-gardens.

The Society of Arts tablet is one erected on Bolton-house, Windmill-hill, Hampstead, lived in by Joanna Baillie.

The London County Council tablet is in blue. Most of those put up by the Society of Arts are in red, though some of the older tablets are in blue. The same tablet has always been used by the Society since the first one, which was erected on Byron's house in Holles-street, in 1867. This tablet was taken down when the house was altered, and a large medallion was substituted by the owners of the premises, Messrs. John Lewis and Co.

It has not been easy to ascertain precisely who was responsible for the design of the Society's tablet. The original proposal for the erection of memorial tablets was due to Sir Henry Cole and Mr. (now Sir) George Bartley, in 1864. When the idea was first taken up, the offer of a £10 prize for a suitable design was made, but nothing seems to have come of this. Later on, Mr. Bartley undertook to obtain a design, and with the assistance of Sir Henry Cole, who took a great interest in the matter, various designs were

prepared in the offices of the Science and Art Department under the late Mr. Godfrey Sykes and his assistant. Eventually the matter was placed in the hands of Messrs. Minton, Hollins and Co., of Stoke-on-Trent, who appear to have worked on the suggestions submitted to them, and produced the tablet which was approved and adopted by the Council of the Society.

One of the main objects in the design was that the Society of Arts name should be given, but that it should not be made too prominent, and this object was effectively attained by the ingenious border in which the name of the Society is introduced.

The same design has in all cases been used by the Society, with the solitary exception of the tablet to Milton in Bunhill-row. The architecture of the building there did not admit of the convenient erection of a circular tablet, and consequently the oblong tablet which is now in position was specially designed and erected.

THE NOTTINGHAM LACE TRADE.—MASTERS AND MEN.

For a long time past, the lace manufacturers of Nottingham have been at variance with their workmen. The masters insisted upon lower rates, the men refused to accept them; the masters said it was impossible to go on paying current rates, the men said that all that was necessary was to replace obsolete by

efficient machinery. "If," said the last half-yearly report of the Nottingham Operative Lacemakers' Society, "steps are not quickly taken to replace the obsolete machines by modern ones, Nottingham will very soon bid farewell to that predominating influence over the manufacture of lace which it has held for a century." After much discussion, a revised price list, effecting considerable reductions, was unanimously agreed upon by a joint committee composed of members of the men's Association and the manufacturers' Association, and an agreement had previously been arrived at by both parties that any dispute which they were unable to settle themselves should be referred to the arbitration of the Board of Trade, whose decision should be final. Unfortunately the men repudiated the action of the joint committee, and the manufacturers having served formal notice of their intention to put the revised price list in operation on the 17th instant, the men resolved to cease work. It is not the first time in the controversy that they have refused to follow their leaders.

There can be no question that the lace trade of Nottingham, so far as the making is concerned, is in a bad way. It is passing to Long Eaton, Beeston, Ilkeston—and the Continent. Long Eaton boasts of more than half the number of lace machines working in the district round Nottingham, and more than half the number of operatives working in Nottingham itself. It is the contention of the manufacturers that the trouble in Nottingham is due to the cast-iron methods adopted by the Lacemakers' Union. The manufacturers say that these methods have all tended to drive trade away from the town. Long Eaton has been built up by men who have gone there to escape unreasonable demands, and they give an illustration. At one time there was a run on a certain kind of black lace, and the men who made it were paid a special rate because the work was trying to the eyes, and they could not turn out the material at such a fast rate. Then the demand slackened, and one manufacturer who had some white lace to make that he knew would have to be dyed black, wished to run a few of the black threads that had been left on his hands into the material. But the men refused to carry out the work unless they were given the higher rate. The conditions in the outside districts are quite different. In Nottingham the machine-holders have stuck to their old narrow frames; in Long Eaton they have the best up-to-date machines, both in width and producing capacity, and the auxiliary workers are more numerous, and attend so fully to the needs of the actual operatives that there is the minimum of time wasted. The result is that some of the machines make 300 racks, and even more, per week. The employers can afford to have the extra workers because they are free of the dictation of the Nottingham society. All is done to obtain the most the machines can turn out, and so the lacemaker can afford to work for less per rack than in Nottingham, and still get a bigger weekly wage. In Nottingham, a man who stayed behind at one o'clock (the dinner hour), would be censured by his fellow operatives; at Long Eaton, he may please himself, and it is seldom that men stop their machines for a meal. Almost all the machines running at Long Eaton are of the new wide pattern, and though rates are much lower, wages are better than in Nottingham. In Nottingham, 11d. per rack is paid, at Long Eaton, the extremes in prices are from 5½d. per rack to 7½d. and 8d.

The extent of the migration of laceworkers from Nottingham to the other districts may be gathered from the following figures, taken from an interesting pamphlet recently published by the *Nottingham Daily Express* on "The Lace Trade in Nottingham and District," and showing the number of machines and men working in what are known as "outside districts":—

MACHINES.

It is not possible to obtain the number of machines working in Nottingham, but at the end of last year it was computed that the total Nottingham membership of the society was 2,805, of whom 2,214 were actually working, so that there were fewer operatives employed in Nottingham, the so-called lace town, than in the other districts.

The Nottingham manufacturers complain bitterly of trade union interference, but the men argue

that the fault of the present state of the industry in the town is more with the manufacturer than wtih themselves. He will not supply himself with up-to-date machinery. As to that, Mr. Ernest Jardine, of the great firm of machine builders and merchants of that name, writes:—"We have been making bobbin pressing machines which do the work with one-tenth of the labour in a quarter of the time occupied by the old method. It makes a perfect fit, and it is impossible to spoil the bobbins. We have put in 50 of these at Long Eaton alone. We claim that a manufacturer having these machines can save more than the total cost in the first year. We have offered to put in these machines in Nottingham free of charge, and at the end of three months, if they are not wanted, to remove them. We have succeeded in placing two at Nottingham." At Long Eaton, double handed, they will make 300 racks per week; in Nottingham, 175 or 185 racks is considered a capital week's work.

It is not only the outside districts with which Nottingham has to reckon. Continental competition has become very formidable, more particularly that of Germany and Switzerland. It has been said that nine-tenths of the lace goods exhibited in the windows of Nottingham shopkeepers is made on the Continent. Probably that is an exaggeration, but the "Schiffchem" and the "Barmen" machines, to be found principally at Plauen, in Saxony, and St. Gall, in Switzerland, have played havoc with Nottingham. There are between 3,000 and 4,000 of the Schiffchem machines in Switzerland, they all make the best class of goods, and every one has been made within the last ten years. In addition, there are thousands of hand machines at work in St. Gall and the villages around. At Plauen, the competition is even more formidable. The people there have devoted themselves almost entirely to the manufacture of lace. In Saxony, there are 3,000 machines, most of them making lace. Some few Nottingham firms fought hard against the foreign invasion. One firm when they found that Edelweiss lace was coming into the English market, obtained three machines from France, and made the same goods. Each machine, however, required a very skilful pantographer, whose duty it was to trace the pattern whilst the apparatus was at work. These men could only have been got from Germany or Switzerland, and the manufacturers there had entered into a compact for the purpose of preventing any of their workmen from leaving the country. It is said that last season, when lace collars were being worn by every girl, not more than 150 machines in Nottingham could have made such articles. In Switzerland alone there were between 2,000 and 3,000 machines capable of turning them out.

It is not surprising that under the circumstances narrated the lace making, as distinguished from the lace finishing trade, is leaving Nottingham for the outside districts, more especially Long Eaton, and the Continent. Opinions differ as to whether it can be recovered, but it may be said with confidence that recovery is only possible if masters and men mend their methods, if the masters become more alive to the need of up-to-date machinery, and the men free themselves from the present crippling conditions of service.

*THE RELATION BETWEEN POPULATION AND AREA IN INDIA.**

The term "density" may be applied to population in a sense merely numerical, or it may be taken to involve the economical consideration of relation to the means of subsistence. Used in the latter sense, with reference to a population producing the food it consumes, the determining factor is practically the fertility of the local resources. India comes under this head. Its population is mainly vegetarian, and the greatly predominating occupation is agriculture. In analysing the distribution of its population, therefore, the first consideration is the relative fertility of the varions tracts, and using the geographical divisions of the country as the base and remembering that tropical conditions prevail, the essential feature to be taken into account is the rainfall. Speaking generally, the concentration of population tends to vary directly as the rainfall, and inversely as its seasonal variability. There are several important instances in which this tendency is not apparent, but here it is kept in abeyance by special circumstances, such as unhealthy climate, political disturbances, or paucity of cultivable land on the one hand, and on the other by exceptional facilities for supplementing the rainfall by artificial irrigation.

There are few countries of any considerable size so uniform in the distribution of their population that the figure of their average density serves any purpose but that of the very broadest comparison, and its chief use in statistics is as a screen on which to illustrate its component variations. In India, with its unusual range of climatic and geographical variety, the average is peculiarly meaningless, and, compounded as it is largely from its two extremes, the density it implies actually prevails over but a comparatively small proportion of the area which contributes to it. The urban element in the population, again, enters but to a trifling extent into the calculation, as is only to be expected in a country so markedly agricultural in its pursuits and so largely self-supporting. As a rule, the most densely peopled tracts, except just round the large industrial seaports, are remarkable for the paucity of their urban aggregates beyond the size of the ordinary local market town. There are, on the other hand, parts of the country, especially in Native States, where a comparatively large town is found in the midst of a very thinly populated neighbourhood, to which it serves as a centre of commerce. The political and military considerations which used to determine the situation and

* Abstract of paper read by J. A. Baines, C.S.I., before Section F of the British Asociation meeting at Cambridge.

prospects of an important town are now superseded almost everywhere by those connected with transport and manufacture. ~~Except, however, along the coast~~ and trunk lines of railway, the smaller urban centres prosper and wane with the fortunes of the surrounding peasantry.

The nature and extent of the shifting of the distribution of population of late years are subjects upon which the recent famines have made it difficult to reach satisfactory conclusions, nor were the exceptionally favourable circumstances of the preceding decennial period much more instructive. At best the rate of growth in the long-settled tracts does not appear to be other than moderate compared with that prevailing elsewhere, but the evidence of a state approaching congestion is not altogether convincing. Between 1881 and 1891, the most thickly peopled tracts showed a rate of increase very much below that of those with a more scattered population, but it is not improbable that in the latter the later census was far more accurately taken, so that much of the growth must be discounted accordingly. On the other hand, during the last decennium, the denser tracts showed, on the whole, a higher rate than the rest; but here, again, allowance must be made for the fortunate immunity from famine enjoyed by the former, as also for a certain multiplication of the means of subsistence which has characterised some of them.

On the whole, it appears certain that under present conditions any increase in population that occurs will fall directly upon the land, and in most parts of the country the means exist for meeting that pressure, at all events for some considerable time. Cultivable land not yet taken up is found in most provinces and States. In some comparatively remote regions this area is large and continuous, and is now being placed within reach of immigrants by the extension of railways. Elsewhere the sinking of wells has intensified the cultivation, and the introduction of additional water supply by means of canals has rendered large areas productive which were before sterile. Congestion may be thus staved off for a generation, but must come, as the line of increase remains the same. There are, however, signs of the beginning of a process of diversion from agriculture to other industries. The urban population has recently shown a tendency to increase at a slightly higher rate than the rural, and though in the famine-stricken tracts this may be in part attributed to the traditional tendency of the field labourer to wander towards the doles and labour market of the nearest town, the growth of the seaports and manufacturing centres testifies to a real movement away from the fields. Whether the movement be permanent or, as in many cases it is known to be, merely seasonal, there is no doubt as to the increased advantage which is being taken of the openings afforded by the development of new undertakings within the last twenty years or even less, and the villager earns away from home more than the subsistence he used to himself produce there. The further step of emigration for employment out of India and its immediate neighbours is an outlet which also shows signs of expansion, but, like the migration to the plantations or factories, it is a matter of sentiment and custom, and once acclimatised, often leads to a regular flow out and back. That the returned emigrant's savings are ultimately invested in the purchase of land in his birthplace is a matter that will have to be taken into account by the next generation.

ALCOHOLIC BEVERAGES AT HOME AND ABROAD.

Some interesting statistics have recently been prepared by the United States Department of Commerce and Labour bearing upon the question of the consumption of spirits, wine and beer, for the latest available period, in the principal European countries and in the United States. In the United Kingdom the amount consumed works out as follows:—Spirits, 58,318,000 proof gallons; beer, 1,500,710,000 gallons, and wine, 16,646,000 gallons. In the United States the figures are 117,252,000, 1,449,879,000 and 38,720,000; in Germany, 124,313,000, 1,782,778,000 and 113,583,000; in Russia, 172,530,000, 151,633,000 (for wine there are no statistics of consumption in this country). In France there are 97,178,000 proof gallons of spirits consumed, 289,103,000 gallons of beer, and 1,342,830,000 gallons of wine; the corresponding figures for Sweden are 10,730,000, 44,440,000, and 808,000; for Belgium, 9,895,000, 395,285,000, and 8,948,000; and for Italy 11,150,000, 6,726,000, and 1,045,961,000. In the case of European countries the figures for spirits include only those quantities which are used in the form of beverages, the quantities used in the arts and manufactures being uniformly excluded. There are no exact data for the United States, as all the spirits entering domestic, including industrial consumption, are taxed at a uniform rate. Authoritative estimates place the quantity used in the arts and manufactures in the United States at about 10,000,000 gallons. As regards the *per capita* consumption France shows the heaviest consumption of the most concentrated beverage, spirits, viz., 2·51 gallons per inhabitant, the other countries following in the order of their *per capita* consumption being Sweden, 2·13; Germany, 2·11; Belgium, 1·42; United Kingdom, 1·38; United States, 1·33; Russia, 1·29, and lastly Italy with only 0·34 gallons. The *per capita* consumption of spirits in the United States is 1·33 proof gallons. Statistics of the average consumption of beer per head of the population reveal the fact that Belgium stands at the head of the nations, the *per capita* consumption being 56·59 gallons; second in order is the United Kingdom with 35·42 gallons, while Germany, which shows the largest absolute figures of consumption in

the matter of *per capita* consumption, takes third place with 30·77 gallons. The United States follows with 18·04 gallons, Sweden and France with 8·83 and 7·48 gallons, Russia, 1·13 gallons per inhabitant, while Italy is still lower, viz., 0·20 gallon. The consumption of wine may be said to be concentrated in two countries, chiefly France and Italy, both the absolute and *per capita* consumption showing that wine in these countries is a common article of consumption showing that wine in these countries is a common article of consumption rather than an article of luxury, used only by the favoured few. The figures of *per capita* consumption of wine in these countries—34·73 gallons in France and 31·86 gallons in Italy—are almost identical with those shown for beer by the United Kingdom and Germany. The consumption of wine in other countries is relatively insignificant, only Germany with 1·93 gallons per inhabitant, and Belgium with 1·28 gallons, showing a *per capita* consumption exceeding one gallon, the estimated *per capita* consumption in the United States being 0·48 gallons. The following figures will show the total quantity of alcohol of 50 per cent. strength consumed in the form of beverages in the countries named, beer and wine having been expressed in terms of spirits of standard (*i.e.*, 50 per cent.) strength by assuming an average alcohol content of 5 per cent. for beer and 10 per cent. for wine. Reduced, as it were, to common terms, the consumption of alcohol of 50 per cent. strength as beverages in the countries in question is as follows: United Kingdom, 211,718,000 gallons; France, 394,654,000; Germany, 325,307,000; Italy, 221,015,000; Russia, 187,713,000 (consumption of wine not included); Belgium, 51,213,000; Sweden, 15,354,000; and the United States 259,984,000 gallons. In the latter case 10,000,000 gallons of spirits used in the arts are excluded. France shows the largest *per capita* consumption of alcoholic beverages, viz., 10·21 gallons, while Belgium, owing to its heavy beer consumption, follows next in order with 7·33 gallons. Italy with 6·61 gallons, Germany with 5·53 gallons, and the United Kingdom with 4·99 gallons are the older countries which may be said to excel in the consumption of alcoholic beverages. The United States with 3·23 gallons, Sweden with 3·05 gallons, and Russia with 1·39 gallons of average consumption wind up the list of the countries in question.

COMMERCIAL EDUCATION IN JAPAN.

Within the last decade, the most important commercial nations of Europe have discovered the importance of higher theoretical commercial education, and have established institutions devoted to commercial studies, thereby acknowledging this system of education to be of equal value to that afforded by the universities. At a much earlier period, Japan devoted attention to this important branch of education. Commercial schools were established in an almost incredibly short time. As early as 1873, the first commercial institute was established in Tokyo. Since that time, similar schools have been established in various parts of the Empire. In 1884, the commercial schools were regulated by ministerial decree, and in 1899 a general law was passed concerning commercial educational institutions. In accordance with this law, the commercial schools are divided into two categories:—(1) The schools of the first class take students in their fourteenth year, after they have graduated from a four year old course in a higher ordinary school, and demand a knowledge, of at least one foreign language. They offer a three years course, which may be increased by one year if necessary. The number of hours of school work per week which may be increased by one week, which may be taken by a student, shall not exceed thirty-three. (2) In the schools of the second class, instruction continues for a period of three years. Pupils of ten years of age may enter, and the number of hours of school work shall not exceed thirty per week. Above the commercial schools of the first grade, stand the commercial high schools, so that Japan has, in fact, three grades of commercial schools which differ from the usual European schools, in that they are built one upon the other. This difference has an influence upon the thoroughness of education, since a student who has passed through the series of schools, and has put in eight or ten years' study in commercial branches, must be better equipped than one who has had only two or three years' preparation. At present there are commercial high schools at Tokyo, and at Kobé. The one at Tokyo was founded in 1875, by Viscount Mori, as a private school. In 1887 this school was re-organised, under the title Koto Shogyo Gokko, and it adopted some of the methods of the Ecole des Hautes Etudes Commerciales of Paris, and the Institut Supérieur de Commerce of Antwerp. The business men of Japan were not altogether friendly to the system, because they preferred to take young men without much training, and mould them as they desired. The school at Tokyo has endeavoured to prove its value to Japanese commercial circles, and it has had the assistance of a committee of leading merchants, bankers, and State officials. There are three courses available, a preparatory course of one year, a course of three years, and a graduate course of two years. The preparatory course includes the following studies:—Japanese writing, Japanese composition, mathematics, book-keeping, technology, practical physics, general law, general economics, English, French, German, Russian, Spanish, Italian, or Korean languages, gymnastics, and military exercises. The higher course includes the following studies:—Economics, Japanese commercial law, comparative international commercial law, commercial composition and office management, economic relations of Eastern Asia, history of the relations of the foreign powers, criminal law, English

composition, and other foreign languages. In the professional division of the higher course the student may also choose work in connection with commerce, railways, banking, shipping, insurance, and the consular service. The students in this course have to pass an examination and prepare a dissertation on some subject relating to commerce to enable them to gain the title of "doctor of commerce." Notwithstanding the rapid progress Japan is making, it is evident to those interested that there is a necessity for greater attention to foreign languages. In 1897, by Imperial decree, the study of languages in the school was made independent. The instruction extends over three years, with twenty-four hours weekly in English, German, French, Russian, and Spanish, and twenty-seven hours weekly in Chinese and Korean. The affairs of the school are managed by a committee on education, which includes representatives of the Minister of Education, and leading business men, as well as the director of the school. The immediate supervision of the school is in the hands of the director. The faculty consists of fourteen ordinary professors, twelve head professors, and seven secretaries. In the college for foreign languages there are fifteen ordinary professors, eight head professors, and three secretaries. In this school and that at Kobé there are from ten to fourteen foreign professors almost continually at work in the foreign languages department. The sample office is also in charge of a foreigner. In course of time these professors are to be replaced by Japanese. In connection with the commercial high school there is a commercial museum, containing a collection of various wares. In 1890 the school went into its new building, which was erected at a cost of £29,000. In 1889 steps were first taken to establish a commercial high school at Kobé. The organisation and the lecture course correspond to those of the school at Tokyo, but the preparatory course extends over only one year, and there is but one other course of three years. The main difference between the schools of Kobé and Tokyo consists in the separation of the prepatory course at Kobé into two departments, the first for pupils of middle schools and the second for pupils of the commercial middle schools.

CUBA AND BRITISH TRADE.

A report from Mr. Lionel Carder, His Majesty's Minister at Havana, upon the trade and commerce of Cuba, has just been issued, and is of exceptional interest. It shows that the island has recovered from the ravages of civil and foreign war, and that very considerable economic development may be expected in the early future. Mr. Carder thinks it probable that the value of the imports in 1905 will be at least £21,000,000, or 65 per cent. more than in 1903. The production of sugar is now as large as in the best year before the insurrection, and the steady increase in the output must mean increased employment for British vessels. If, too, the cultivation of cotton assumes the proportions expected, further stimulus will be given to the British shipping engaged in the direct carrying trade by increasing opportunities for getting return cargoes. Experiments, some of them on quite an extensive scale, have shown that a superior class of cotton can be raised in Cuba. The only question remaining in doubt is whether there is sufficient labour available at reasonable prices for pulling the cotton if planted in considerable quantity. If this difficulty can be got over—and labour is the crux of the cotton question—there is every reason to expect that the cotton industry in Cuba will soon come to be of great importance. If so, large shipments will be made to the United Kingdom, thus increasing the commercial movement between the two countries, and greatly benefiting the direct carrying trade in British bottoms. The variety of cotton found to grow best in Cuba is Sea Island, which is of fine quality and long staple.

The imports from the United Kingdom and British possessions show a satisfactory increase, not only in amount but in the proportion they bear to the total imports which is now 20 per cent. as against 18 per cent. in 1902 and 15 per cent. in 1901. The following figures show the position:—

Country.	Value.		Proportion.	
	1902.	1903.	1902.	1903.
United States and Possessions	£ 5,156,120	£ 5,525,806	Per cent. 42½	Per cent. 41½
United Kingdom and British Possessions	2,175,664	2,542,845	18	20
Spain	1,908,332	1,822,707	15¾	14½

By far the largest increase, amounting to £354,000, occurred in textile goods, after which came metals and machinery, coal and coke, and manufacturers of leather, with respectively £156,000, £147,000, and £106,000. A large proportion of the textile goods comes from the United Kingdom. The value of the exports in 1903 increased more than £2,500,000 as compared with 1902, but there was very little difference in the proportions.

Country.	Value.		Proportion.	
	1902.	1903.	1902.	1903.

With the increase of wealth there is likely to be a largely increased demand for textile goods. The coloured population are fond of dress, and spend their money freely in such articles when they have

it. This would of course benefit British trade more largely in proportion than that of any other country. Mr. Carden thinks there is want of enterprise on the part of British manufacturers, and he relates the following incident in support of his contention. The Minister had received a letter from a British manufacturing firm asking him to assist them in placing on the Cuban market an agricultural appliance which, if capable of giving the results claimed, would create almost a revolution in cultivation in Cuba. Mr. Carden referred to a gentleman of very high standing, who was especially well qualified to bring it to the notice of Cuban planters. He was favourably impressed with its possibilities, and wrote to the firm offering, if they would send out one of the machines, to pay all the expenses and give it a good trial. To this they replied that the only terms on which they could send one out would be those of purchase, adding that the demand for the machine was so great that it was impossible for them to cope with it, an observation that only admitted the inference that their correspondent must consider himself as very fortunate to have the opportunity of buying one at all. This was the end of the matter, the impression left on the Cuban gentleman's mind being that the manufacturers were quite indifferent as to whether they did business or not. Mr. Carden adds that the machine was an expensive one, costing in the United Kingdom £200, and if, after being properly tested, it had proved suitable to the conditions of soil and climate prevalent in Cuba, there is little doubt that a very large market could have been opened up for it in Cuba.

BRITISH TRADE IN SWITZERLAND.

Switzerland's best customer is Great Britain. Of the exports of principal Swiss manufactures in 1903 the United Kingdom and her Colonies took more than 27 per cent., and the Swiss are anxious to do more trade with us. In his exhaustive report on the trade of Switzerland for 1903, just issued, Mr. J. C. Milligan, who is British Commercial Agent in that country, says, "There is at the present time a very great desire among the leading Swiss merchants, which has also found expression in the Swiss Press, that both the United Kingdom and France should have a larger share of Switzerland's market." Why is it then that the British share in the supply of Switzerland's requirements of manufactured goods for home consumption only amounted last year to 10·9 per cent.? If the imports of cotton goods from the United Kingdom, which accounts for as much as 56 per cent. of the British exports of manufactures to Switzerland, are left out of consideration, the unsatisfactory condition of the export trade of the United Kingdom to Switzerland becomes more apparent. To quote Mr. Milligan, "Germany has by far the greatest share in the Swiss trade. In the year under review the exports from Germany to Switzerland of finished goods amounted to £8,026,000, or if the value of her cotton exports be deducted, £677,000, we have a total of £7,349,000 for all other classes of of manufactures. The United Kingdom supplied cotton goods to the value of £921,900 to Switzerland, and on deducting that amount from the total exports, her share in all classes of finished goods amounted to only £719,600, against, as already stated, £7,349,000 supplied by Germany, and £2,478,000 supplied by France." Mr. Milligan points to the bicycle trade. During the last five years nearly 74,500 machines, representing a value of £655,000, have been imported into Switzerland, of which 49,500 came from Germany, 12,500 from France, 6,000 from the United States, and 1,700 from the United Kingdom. The imports are increasing yearly, last year's total of 17,170 machines being the highest, but the imports of British bicycles steadily dwindled until 1903, when there was a slight recovery. Mr. Milligan says some very useful information has been given to him by a large Swiss dealer with regard to the cycle trade in Switzerland, which he will supply to any British manufacturers interested if they will apply to him. British prices seem to be too high for the Swiss. Many British manufacturers do not seem to be aware of the commercial position which Switzerland occupies among the other markets of the world, or know that she has a demand for such a large value of imported manufactured goods. British trade with Switzerland is not pushed like that of other countries. "If," writes one of the principal journals in German Switzerland, "British manufacturers would only follow the advice of the British Commercial Agent, and copy the Germans, Italians, and other nations, in opening up relations with Switzerland, their exports would most certainly increase. There is no reason why we should give German and French commercial travellers the preference if the goods are equal in finish and price." The difficulty is that British commercial travellers are less well equipped for getting business. If it is not possible to send commercial representatives possessing a knowledge of German and French, Mr. Milligan suggests the appointment of local Swiss agents, able to correspond in English.

AUSTRALIAN FORESTRY.

The importance of forest conservation is beginning to receive increased attention in the Commonwealth, where the revenue from the various State forest lands remains considerably below that obtained in countries possessing far less wealth of timber. In New South Wales the forests, contrary to the popular idea in Europe and America, extend over almost the whole area of the State, excepting portions of the Monaro, Lachlan, Murrumbidgee districts, and the trans-Darling region, where extensive treeless plains occur, clothed with salt-bush, scrub, or species of natural grasses. There are at the present time nearly six and

a-half million acres of forest reserves in the State. In South Australia there are nearly 200,000 acres of forest reserves and plantations; in Queensland, where forest conservation is of recent date, the reserved areas form a total of over three million acres; in Victoria the forest reserves cover a total area of 4,679,540 acres out of 11,797,000 acres of forest country, the balance being mostly timber country difficult of access; in Western Australia a beginning has been made by establishing forest reserves forming a total of over a million acres out of an estimated total of 20,000,000 acres; while in Tasmania about 33,300 acres have been reserved for timber-planting and growing. The total area of forest land in the latter State is about 4,000,000 acres, and it has been estimated that the forest lands of the Commonwealth cover an area of over 60,000,000 acres. The trees met with are chiefly species of eucalyptus, angophora, and other genera of the order myrtaceæ. The prevalence of the eucalypti, and the large extent covered by the forests, give the country a rather monotonous aspect; but the park-like appearance of the open forests, and the beauty of the many flowering shrubs, win admiration in spite of the sameness of the trees; while even the dull, greyish blue of the foliage of the gum trees, when relieved by the yellow blossoms of the wattle, including the graceful myall, or the beautiful and shapely kurrajong, is not without its attractiveness. The trees are, for the most part, straight and cylindrical in the trunk, and when full grown, their first branch is at a considerable height from the ground. The roots of the eucalyptus often lie at no great distance from the surface soil, an adaptation of nature to the peculiar climatic conditions of the country. The finest specimens of many of the timber trees, those yielding the most valuable timber, are found on ridges and hill sides, in places frequently too rough and stony for cultivation. In Western Australia the most valuable indigenous timbers are the jarrah, twart (or torart), sandal-wood, karri, and several others. In Queensland cedar timbers are abundant, also in the northern portions of New South Wales, some of the logs obtained being of enormous size. One characteristic feature of Australian hard-wood trees, of which there exists an almost endless variety, is the great size of the beams which may be obtained from them, as well as for the extreme toughness and durability of their wood; the grey ironbark having a resistance to breaking eqnal to 17,900 lb. per square inch, as compared with a mean of 11,800 lb. for English oak, and 15,500 for teak. None of the other timbers have so high a resistance to breaking as this description of iron-bark, but nearly all the varieties have a greater strength than oak. The quality of the wood is materially influenced by the soil on which the trees grow, while the absence of branches for the greater portion of the height enables the timber to be obtained to the best advantage; and as full-grown trees of most varieties are rarely less than 100 feet high, with corresponding girth, the quantity of timber obtainable from the virgin forests is very large. In New South Wales the timbers of commercial value, many of which are found in the other States, include white or she-ironbark, narrow-leaved ironbark, broad-leaved ironbark, mugga, or red iron-bark, blackbutt, white mahogany, tallow-wood, spotted gum, grey box, red mahogany, grey gum, forest red gum, Sydney blue gum, and turpentine, the latter resisting the attacks of white ants. One of the most useful trees is the red cedar, the wood of which, somewhat resembles mahogany, is well adapted for the finer kinds of cabinet-makers' work. Some of the cedar trees grow to immense size, as much as 2,500 cubic feet of valuable timber having been obtained from a single tree. Many of the woods of the minor trees are beautifully grained, and capable of receiving the highest polish, while others are fragrantly perfumed. These woods are adapted to the finest description of cabinet-making, and it is strange that their merits should have so long escaped attention. Amongst these trees may be mentioned the rosewood, tulipwood, yellowwood, white maple, white beech, myall, marblewood, mock orange, and many others. Besides their use for cabinet-making, many of the brush timbers are of great utility for the rougher kinds of carpentry; while some, both hard and soft woods are admirably adapted for coach-builders' and coopers' work. "Colonial deal" is an excellent timber. and is obtained in very large scantling, the tree frequently reaching 120 feet in height. It is soft, close-grained, easily wrought, and remarkably free from knots. Its use, therefore, is extensive for cabinet-makers' work and house fittings. The value of the exports of Australian timber, dressed and undressed, from Commonweath ports in 1903 was £745,490, of which the undressed timber, chiefly from Western Australia, represented £739,317.

CORRESPONDENCE.

STREET ARCHITECTURE.

In the course of the paper read by Mr. Jackson last week, he said, "Foot passengers, however, do not run very much against one another, and need never do so if everybody observed the rule of the footway, and to help this he would put up "direction labels—'Keep to the Right.'" I do not think this is good advice, because the natural inclination of 75 per cent. of foot passengers is to bear to the left, and I believe all would but for a desire to conform to what is expected of them. It is this wrong existing rule, coupled with the stupidity of two or more persons sianding in the middle of the pavement talking together, that renders locomotion so irritating and slow.

G. G. MACWILLIAM.

20, Bartlett's-buildings, Holborn-circus, London, E.C.,
December 26th, 1904.

The last number of the *Builder* contains the following remarks on Mr. Jackson's paper on "Street Architecture":—The often-vexed question of grouping and symmetrical design in street architecture, as against the effect of individuality, or independent treatment for each property, naturally comes up once more; and we are glad to find that Mr. Jackson recognises the importance of symmetrical architectural treatment, if he does not advocate it in all cases, and he commented strongly on the manner in which the design of Regent-street, "the one fine and consistent piece of street architecture in London," has been practically destroyed by the intrusive alterations which have been permitted to be made in it." To call Regent-street, in its original state, "fine" architecture is what we should hesitate to do *sans phrase*, but "consistent" at all events it was, and has now ceased to be so, and people are beginning to find, when it is too late, that they have destroyed something which was of architectural value to London. Regent-street would have been respected had it existed in Paris. An owner of one or two houses in the Place Vendôme wished some little time ago to raise them, thereby spoiling the architectural design of the square: he was not allowed to do so.

Our own opinion is that massing of street architecture, if not for a whole street, at all events in large blocks, in a symmetrical design, is an almost necessary expedient if the highest dignity is to be given to the architecture of a city. It is owing to the prevalence of this symmetrical street architecture that Paris has that grandiose air which makes it seem a city so much more, in the full sense of the word, than our own capital. Of course it may be said that the Paris street architecture is somewhat cold and formal and wanting in variety; so it is, but something must be given up either for the picturesque on one side or the stately on another; and to our mind it is the stately element that is most proper to a capital city, at all events. The manner in which the County Council have let slip the opportunity for stately and symmetrical design in Aldwych and Kingsway, after laying the foundation for it by instituting a competition for designs, is absolutely lamentable. The mischief is done now in Aldwych, but there is still some place for repentance in regard to Kingsway.

The demand for special treatment and special material for shop front architecture was rather more emphasised by Mr. Jackson than we should have expected. He urged that was no reason why stanchions and bressummers should not be treated architecturally if there was an absolute demand for entirely glazed shop fronts.

We do not think that steel bressummers and stanchions are as capable of as much architectural effect as stone piers and arches, though we quite agree that if that glass ground-story is indispensable, the means of supporting the building above it should be openly shown, and treated in a way characteristic of the material; and it is too true that this is very seldom done at present, and we see arches or imaginary stone lintels, that could not possibly stand put up in order to comply with what are supposed to be the demands of architecture. That of course is all wrong; and visible steel structure is much better than sham stone structure. But, after all, real stone structure is better than either; and whatever the "honesty" of the steel construction, we have still the disagreeable effect of the empty space as the base of an architectural design. But the question is, whether people are not getting hold of the whole matter the wrong way about. Is it really necessary to the prosperity of a shopkeeper that he should have the whole front of his shop scooped out and filled with plate glass? Is it not merely a superstition of the trading mind? And is it not possible to convert the shopkeeper to a perception that a dignified architectural masonry front, even if arched, is worth more to his trade than filling up the spandrels with glass?

Mr. T. G. Jackson communicated the following letter on the Strand improvements to *The Times*:—

The notice which appeared in *The Times* of my address at the Society of Arts on the 20th inst., and the attention it has received from some of your contemporaries, encourage me to ask for an opportunity of continuing in your columns the subject of the Strand improvements.

Out of many suggestions for a frontage line between St. Mary's and St. Clement's churches, the London County Council has chosen the cheapest and the worst. The frontage line now laid down lies at a very awkward angle with St. Mary's Church, and when produced cuts into the middle of the tower of St. Clement's. The street, so arranged, would have an irregular, haphazard effect, entirely wanting in the regular dignity and beauty proper to so great a scheme as the alteration of the most important thoroughfare in the capital of the Empire.

Admitting that Mr. Hamo Thornycroft's fine scheme is too costly to be entertained. I would point out that three other proposals have been before the Council which more or less avoid these mistakes, and that the one proposed by the Royal Institute of Architects and that suggested by Mr. Riley, the architect of the Board, do not involve a ruinous sacrifice of ground value, considering the importance of the occasion. I trust it may not be too late to urge the reversal of a decision so unworthy of a great opportunity.

Another serious danger which threatens the architectural effect, if we may judge by what has been begun, is the enormous scale of the buildings that seem to be contemplated. The scale proper to the street is given by Somerset House and the two churches, which rank among the most valuable architectural ornaments of London, and have always, till lately, dominated every view of the Strand, and should continue to do so. But the improvements committee of the Council promise us "an imposing effect for the

buildings to be erected on the northern side of the Strand," from which we may anticipate a continuation of the enormous pile next the new Gaiety Theatre, which will reduce the churches to insignificance. From this disaster, I hope some expression of public opinion will save us. There is plenty of room for "imposing effects" in Kingsway and Aldwych, where there will be no old buildings to spoil. We do not want them in the Strand. The County Council owns the site, and can make any rule they please as to scale. A reduction in height would no doubt mean some pecuniary sacrifice, but I venture to think that in no other capital of Europe would that be allowed to prevent so grand a scheme from being carried out in the best way for architectural effect. If purely commercial considerations are always to prevail when the question between an artistic and an inartistic way of doing things touches our pockets, surely the elaborate system of art teaching we so diligently promote throughout the country may be suspected of insincerity and of being little more than an expensive imposture.

T. G. JACKSON.

OBITUARY.

SIR ISAAC LOWTHIAN BELL, BART., LL.D., F.R.S.—Sir Lowthian Bell, who died at his residence, Rounton Grange, Northallerton, on the 20th inst., had been a member of the Society of Arts since 1859. He was elected on the Council in 1876, and in 1895 he was awarded the Albert Medal of the Society "in recognition of the services he has rendered to Arts, Manufactures, and Commerce by his metallurgical researches, and the resulting development of the iron and steel industries." He was born on February 15, 1816, at Newcastle, his father being an ironmaster, Mr. Thomas Bell, and his mother, a daughter of Mr. Isaac Lowthian, of Newbiggin, in Cumberland. After attending Edinburgh University and the Sorbonne, Paris, he spent some time in travel on the Continent, and then, at the age of twenty-four, entered the Walker Ironworks, near Newcastle, in which his father was a partner. There he remained till 1850, when he became connected with chemical works at Washington, in North Durham. Under his direction, these became one of the most important concerns of their kind in the North of England. He greatly enlarged them, and laid down extensive plant for the manufacture of an oxychloride of lead introduced as a substitute for white lead by his father-in-law, Mr. H. L. Pattinson, F.R.S., with whom he was associated in the business at Washington. There, too, was introduced in 1860 almost the first plant in England for the manufacture of aluminium by the Deville sodium process. Soon after the discovery of the main bed of Cleveland ironstone near Middlesbrough by John Vaughan, in 1850, in conjunction with his brothers Thomas and John, he started iron works at Port Clarence, on the north bank of the Tees. In the development of the Cleveland iron industry his firm played a very important part, and what has been the extent of that development may be judged from the fact that whereas the district in 1850 produced less than 25,000 tons of pig iron, at the present time Middlesborough accounts for about one quarter of the total output of this country. The establishment of a chemical laboratory in connection with the Clarence works shows how fully Bell realised the importance of the scientific study of industrial processes, and his own researches on the chemistry of iron and steel, some of which have been translated into French and German, have become classic. Many of the most important of these appeared first in the form of papers read before the Iron and Steel Institute, and a number of them were subsequently collected and published in a thick volume entitled "The Chemical Phenomena of Iron Smelting." Sir Lowthian was also the author of a book on the "Principles of Iron and Steel Manufacture," as well as of many papers contributed to other scientific societies. He was one of the original founders of the Iron and Steel Institute in 1869, he filled the office of president from 1873 to 1875, and in 1874 he became the first recipient of the gold medal instituted by Sir Henry Bessemer the year before. He was a past president of the Institution of Mechanical Engineers.

ADMIRAL SIR ERASMUS OMMANNEY, K.C.B., F.R.S.—Sir Erasmus Ommanney, who died at Southsea, on Wednesday, 21st inst., had been closely connected with the Society of Arts for many years. He was elected a member in 1864, joined the Council in 1870, and was a vice-president from 1874 to 1887. He was a frequent attendant at the evening meetings, and the original Chairman of the African Section, which was founded in 1874. He was born in 1814, and was the seventh son of Sir Francis Molyneux Ommanney, for many years M.P. for Barnstaple, and well-known as a Naval agent. He entered the Navy in August, 1826, under the care of his uncle, John Ackworth Ommanney, then captain of the 74-gun ship *Albion*, which in December convoyed to Lisbon the troops sent out for the defence of Portugal against the Spanish invasion. From Lisbon the *Albion* joined the Mediterranean fleet, under the command of Sir Edward Codrington, and took an effective part in the battle of Navarino, on October 20, 1827. Having passed his examination in 1833, he was promoted on December 10, 1835, to be lieutenant, and a few days later was appointed to the *Cove*, a small frigate under the command of Captain (afterwards Sir) James Clarke-Ross about to proceed to Baffin's Bay for the relief of a number of whalers reported to be caught in the ice. The objects of the expedition were successfully carried out, notwithstanding the extreme danger of the navigation during the winter months. Lieut. Ommanney was then for three years flag-lieutenant to his uncle, Sir

J. A. Ommanney, on the Lisbon station and in the Mediterranean; and on October 9, 1840, he was promoted to be commander. For three years he commanded the *Vesuvius* steamer in the Mediterranean. On November 9, 1846, he was promoted to the rank of captain, and during the years 1847-48 he was employed under the Government Commission in Ireland, carrying into effect the relief measures and the new Poor Law. In 1850-51 he commanded the *Assistance* in the Arctic search expedition, under Captain Horatio Austin, and was the actual discoverer on August 25, 1850, of the first traces of Sir John Franklin, which, on a fuller examination, proved that his ships had wintered at Beechey Island. He also directed an extensive system of sledge journeys, by which the coast of Prince of Wales Land was laid down. On his return from the Arctic he was appointed Deputy Controller of the Coastguard, and on the outbreak of the Russian war was sent to the White Sea in command of a small squadron which, during the summer of 1854, blockaded Archangel, prevented all coasting trade, and destroyed large quantities of Government property. In 1855 he was captain of the *Hawke*, a ship of 60 guns, in the Baltic, and was employed for the greater part of the time as senior officer in the Gulf of Riga, where a rigid blockade was kept up. In 1857 he commanded the 80-gun ship *Brunswick* in the West Indies. He obtained flag rank on November 12, 1864, and on March 13, 1867, was made a C.B. He became a Vice-Admiral on July 14, 1871, and an Admiral, on the retired list, on August 1, 1877. A few days later, August 13, he was knighted. He had the medal for Navarino and the Baltic; in 1890 he received from the King of Greece the Cross of Grand Commander of the Order of the Saviour; and on June 26, 1902, the intended date of King Edward's Coronation, he was nominated a K.C.B.

GENERAL NOTES.

INDIAN TECHNICAL SCHOLARSHIPS FOR TEXTILE STUDY.—The Bombay Local Government has recently invited applications from candidates for two scholarships tenable for a period of two years. The recipients are to proceed to England to undergo a special course of study in subjects connected with the textile industry. Each scholarship is of the value of £150 a year, and in addition a second-class passage to and from England, together with the fees charged for special courses of study, will be paid by the Government. One scholarship is to be assigned for a special course of study in accordance with the textile syllabus of recognised English institutions. The recipient of the other scholarship is to undergo a thorough course of chemistry in its application to textile requirements, and especially to textile fabrics. Applications are receivable from those, who, in addition to having been engaged in practical textile work for at least two years, have also passed through the full textile course of the Victoria Technical Institute, or have obtained the B.Sc. degree at the Bombay University. The Government reserves the right to extend these scholarships for a third year in the event of good progress having been shown by those holding them.

AMERICAN IRON AND STEEL PRODUCTION IN 1903.—According to the statistics collected by Mr. James M. Swank, the general manager of the Iron and Steel Association, there was only a slight decline in activity during 1903. The consumption of pig iron fell from 18,436,700 tons in 1902 to 18,039,909 tons. There was a slight increase in the production of open hearth steel, the output being 5,829,911 tons in 1903, as against 5,687,729 tons in 1902. On the other hand, the output of Bessemer ingots was only 8,592,829, as against 9,138,363 tons in 1902. Pennsylvania has been the chief centre of the steel industry, having produced 1,186,284 tons of steel rails, as against 1,760,472 tons manufactured by all the other States of the Union. Out of a total American output of 1,095,813 tons of structural steel, Pennsylvania produced 1,004,375 tons, or 91 per cent.

IRISH FARM PRODUCE.—In referring to the milk question in the last issue of the *Journal*, it was said that even in Ireland efforts were being made to improve farm management. That much remains to be done in this direction is suggested by the Report of the Irish Agricultural Organisation Society for the eighteen months ended June last. Referring to butter, the Report says that a fruitful source of bad quality is to be found in the carelessness displayed by milk suppliers in cleansing the churns. "These cannot be properly cleansed after each delivery except by a thorough scouring, and this, it is certain, they frequently do not get. To overcome this difficulty, societies are advised to procure and supply, on easy terms of payment, proper steel churns. A case came under the notice of the Irish Agricultural Organisation Society quite recently where milk was supplied in bad condition, and when butter made therefrom had to be sold at 14s. per cwt. under the current market price." As to the treatment of cows, the report says "The feeding and general treatment of dairy cows, in the southern counties especially, is little better than that which is meted out to cattle in Siberia. It is cruel, wasteful, and stupid. Starved cows cannot produce good calves; nor can they put fat in the pail while they are vainly engaged in trying to put it on their sorry carcases." As for Irish butter, the trade are told that more attention must be paid to cleanliness, attractiveness in appearance, and general business details." Still, there is improvement, and refrigeration has done much. "As a result of the installation of cooling machinery and the general use of ice, complaints as to want of 'body' are growing fewer and fewer, and in no single case has a co-operative

creamery, so equipped, had any difficulty in keeping within the limit of 16 per cent. of water imposed by law. And there can be no question whatever that the improved produce and the enhanced value, together with the absence of claims for short weight, have more than justified the enterprise of those societies which have made this addition to their equipment."

ALIEN IMMIGRATION.—So much is being said just now about the increase in alien immigation, that it may be useful to quote the official figures as given for last month and the eleven months ended November 30, 1904, comparing them with the corresponding period of last year. The total number of aliens landed in the United Kingdom in November, 1904, numbered 18,325, as against 13,433 in the corresponding month of 1903, but of these 7,824 and 6,449 respectively were *en route* to places out of the United Kingdom. Thus the aliens who arrived to remain in November of this year numbered 10 499, as against 6,684 in 1903, and of these 1,158 and 1,130 respectively were sailors. If the eleven months ended November 30, 1904, are taken, the total number of aliens landed on our shores in 1904 was 180,598, compared with 198,259 in 1903, but of these no fewer than 121,452 were *en route* in 1903, and 94,627 in 1904. The number of aliens not described in the alien lists as *en route* to places out of the kingdom was 85,971, as compared with 76,807 in 1903, or an increase of a trifle under 12 per cent. But as the return points out, it must not be assumed that the whole of the 85,971 come to this country for settlement, "there being, in fact, a large emigration of foreigners from this country, while many of the aliens arriving from Continental ports return to the Continent." Taking the November returns, by far the larger number of aliens, rot *en route*, landed at London—6,147 out of a total of 10,499—but of those *en route*, none came to London, the vast majority going to Grimsby and Hull. It is noticeable that of the aliens landing to stay, more come *via* Hamburg, Bremen, and Bremerhaven, than by any other route, next from Rotterdam, Amsterdam, and Antwerp, and then from Libau. Of the 1,309 Russians arriving here from Libau last month, only 235 were *en route*, whereas of the 905 coming from Finnish ports only 113 were not *en route*.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock :—

JANUARY 18.—"Wireless Telegraphy and War Correspondence." By CAPTAIN LIONEL JAMES. SIR WILLIAM HENRY PREECE, K.C.B., F.R.S., will preside.

JANUARY 25.—"London Electric Railways." By the HON. ROBERT P. PORTER.

FEBRUARY 1.—"The Navigation of the Nile." By SIR WILLIAM H. PREECE, K.C.B., F.R.S.

FEBRUARY 8.—"Time Development in Photography, and Modern Mechanical Methods of carrying it out." By R. CHILD BAYLEY.

FEBRUARY 15—

FEBRUARY 22.—"Some Misconceptions of Musical Pitch." By JOHN E. BORLAND. (*a*) *Visual*—due to conventional but inaccurate notation; (*b*) *Aural*—volume of tone mistaken for depth, brightness for height.

Illustrated by voices, instruments and diagrams.

MARCH 1.—"The British Art Section of the St. Louis Exhibition." By ISIDORE SPIELMANN.

Dates to be hereafter announced :—

"The Protection of Buildings from Lightning." By KILLINGWORTH HEDGES, M.Inst.C.E.

"The Present Aspect of the Fiscal Question." By SIR CHARLES MALCOLM KENNEDY, K.C.M.G., C.B.

"British Woodlands." By the RIGHT HON. SIR HERBERT MAXWELL, Bart., M.P.

"The Supply of Electricity." By JAMES NELSON SHOOLBRED, B.A., M.Inst.C.E.

"Lake Baikal and its Connection with the Great Siberian Railway." By ARTHUR GULSTON.

"Application of Electricity to the Location of Mineral Deposits." By ALFRED WILLIAMS.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock :—

JANUARY 19.—"The Highlands of Sikkim." By DOUGLAS W. FRESHFIELD. SIR WILLIAM LEE-WARNER, K.C.S.I., will preside.

FEBRUARY 16.—"The Indian Census of 1901." By SIR CHARLES A. ELLIOTT, K.C.S.I., LL.B. The RIGHT HON. LORD GEORGE HAMILTON, G.C.S.I., M.P., will preside.

MARCH 16.—"Manipur and its Tribes." By T. C. HODSON (late I.C.S.).

APRIL 6.—

MAY 11.—"The Manufactures of Greater Britain.—III. India." By HENRY JOHN TOZER, M.A.

COLONIAL SECTION.

Tuesday afternoons at 4.30 o'clock :—

JANUARY 24.—"British Commercial Prospects in the Far East." By BYRON BRENAN, C.M.G., late H.B.M. Consul-General at Shanghai.

FEBRUARY 28.—"The Manufactures of Greater Britain.—I. Canada." By C. F. JUST, Canadian Government Service in London.

MARCH 28.—The Manufactures of Greater Britain.—II. Australasia." By the HON. WALTER HARTWELL JAMES, K.C., Agent-General for and late Premier of Western Australia.

MAY 23.—"The Cape to Cairo Railway." By SIR CHARLES H. T. METCALFE, Bart., M.Inst.C.E.

APPLIED ART SECTION.

Tuesdays, at 4.30 or 8 o'clock:—

JANUARY 31, 8 p.m.—"Calligraphy and Illumination." Two Papers. By EDWARD JOHNSTON and GRAILY HEWITT. LEWIS FOREMAN DAY, Vice-President of the Society, will preside.

FEBRUARY 21, 8 p.m.—"The Queen Victoria Memorial as compared with other Royal Memorials." By MARION H. SPIELMANN. JOHN BELCHER, A.R.A., President of the Royal Institute of British Architects, will preside.

MARCH 21, 8 p.m.—"West Country Screens and Rood Lofts." By F. BLIGH BOND, F.R.I.B.A. G. F. BODLEY, R.A., will preside.

APRIL 11, 4.30 p.m.—"The Monumental Treatment of Bronze." By J. STARKIE GARDNER. SIR GEORGE BIRDWOOD, K.C.I.E., C.S.I., will preside.

MAY 16, 4.30 p.m.—"Popular Jewelry." By MONSIEUR LALIQUE (Paris).

CANTOR LECTURES.

Monday evenings, at 8 o'clock:—

JAMES P. MAGINNIS, Assoc.M.Inst.C.E., M.Inst.Mech.E., "Reservoir, Stylographic, and Fountain Pens." Three Lectures.

LECTURE I.—JANUARY 20.—*Ancient Writing Implements.*—The Stylus and Tabula—Calamus or reed pen—Stencil—Quills, quill nibs, attempts to make quills more serviceable—Substitutes for quills—Silver pens—Ink horn and penner—Ancient writing outfit—Eastern writing implements—Survival of ink horn—Japanese writing box and pens—Their portable writing set—Early metal pens—Steel pens—Barrel pens—First patent for metallic pens—Improvements in steel pens with the object of increasing their ink-holding capacity — Reservoir nibs, various illustrations.

LECTURE II.—JANUARY 27.—*Stylographic Pens.*—Rudimentary forms—Early patents—Rigid points, needle points—Various writing or marking pens—Modern Stylographic pens, Nota Bene, Cygnet, and others—Gold pens, description of manufacture.

LECTURE III.—FEBRUARY 6.—*Fountain Pens.*—Early patents—Solid ink—Various reed arrangements — Self-filling reservoirs, flexible reservoirs, piston and plunger—Modern types of Fountain pens, Swan, Ideal, Conklin, Pelican, Unleakable, Wirt, Quill, Post, Autofiller, Fleet, &c.

DUGALD CLERK, "Internal Combustion Engines." Four Lectures.

February 13, 20, 27, March 6.

HERBERT LAWS WEBB, "Telephony." Four Lectures.

March 13, 20, 27, April 3.

ALAN S. COLE, C.B., "Some Aspects of Ancient and Modern Embroidery." Two Lectures.

May 1, 8.

HENRY WILLOCK RAVENSHAW, Assoc. M.Inst.C.E., Mem.Fed.Inst.Min.Eng., "The Uses of Electricity in Mines." Two Lectures.

May 15, 22.

JUVENILE LECTURES.

Wednesday afternoons, January 4 and 11, 1905, at Five o'clock, CARMICHAEL THOMAS, "The Production of an Illustrated Newspaper." (Two Lectures.)

LECTURE I.—JANUARY 4.—A short history of the early days of illustrated newspapers—Preparations for illustrating events - How sketches are made—Special war artists—Photography on the battlefield—The amateur photographer—Drawing from sketches Siege sketches by balloon post—Mafeking sketches by Colonel Baden-Powell—Production of process plate.

LECTURE II.—JANUARY 11. — Compositors at work—Preparation of stereos—Manufacture of paper—The printing office—Folding and stitching machines—Colour printing—Importance of good titles—The editor's waste-paper basket—Curious sketches: the Russian censor—Foreign illustrated newspapers.

The lectures will be fully illustrated by lantern slides. An exhibition of drawings will be shown on the walls.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JAN. 2...Victoria Institute, 8 Adelphi-terrace, W.C., 4½ p.m. Rev. Arthur Elwin, "Confucianism."

London Institution, Finsbury-circus, E.C., 4 p.m. (Juvenile Lecture.) Mr. Eric S. Bruce, "Balloons."

TUESDAY, JAN. 3...Royal Institution, Albemarle-street, W., 3 p.m. (Juvenile Lectures.) Mr H. H. Cunynghame, "Ancient and Modern Methods of Measuring Time." (Lecture IV.)

WEDNESDAY, JAN. 4...SOCIETY OF ARTS, John-street, Adelphi, W.C., 5 p.m. (Juvenile Lectures.) Mr. Carmichael Thomas, "The Production of an Illustrated Newspaper." (Lecture I.)

London Institution, Finsbury-circus, E.C., 4 p.m. (Juvenile Lecture.) Mr. Eric S. Bruce, "Airships."

THURSDAY, JAN. 5...Royal Institution, Albemarle-street, W., 3 p.m. (Juvenile Lectures.) Mr. H. H. Cunynghame, "Ancient and Modern Methods of Measuring Time." (Lecture V.)

FRIDAY, JAN. 6...London Institution, Finsbury-circus, E.C., 4 p.m. (Juvenile Lecture.) Mr. Eric S. Bruce, "Kites and Flying Machines."

Architectural Association, 18, Tufton-street, Westminster, S.W., 7½ p.m. Mr. Alfred Cox, "Libraries."

Geologists' Association, University College, W.C., 8 p.m. Dr. C. Gilbert Cullis, "The Third Issue of the British Association Geological Photographs." (Illustrated by lantern slides.)

SATURDAY, JAN. 7...Royal Institution, Albemarle-street, W., 3 p.m. (Juvenile Lectures.) Mr. H. H. Cunynghame, "Ancient and Modern Methods of Measuring Time." (Lecture VI.)

Journal of the Society of Arts.

No. 2,720. VOL. LIII.

FRIDAY, JANUARY 6, 1905.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

NOTICES.

NEXT WEEK.

WEDNESDAY, JANUARY 11, 5 p.m. (Juvenile Lectures.) CARMICHAEL THOMAS, "The Production of an Illustrated Newspaper." (Lecture II.)

Further details of the Society's meetings will be found at the end of this number.

PROCEEDINGS OF THE SOCIETY.

JUVENILE LECTURES.

On Wednesday afternoon, January 4th, Mr. CARMICHAEL THOMAS delivered the first lecture of his course, addressed to a juvenile audience, on "The Production of an Illustrated Newspaper."

Mr. Thomas introduced the subject of his lectures, the past history of which is hardly less fascinating than its modern development, by a summary of the earliest attempts which were made to accompany the paragraphs of news in the old news-sheets or tracts by rough drawings. The first attempt of this kind was published in 1607, and the quaint woodcut was entitled "Wofull News from Wales, or the lamentable loss of divers Villages and Parishes (by a strange and wonderful Flood) within the County of Monmouth in Wales, which happened in January last, 1607, whereby a number of his Majesties subjects inhabiting in these parts are utterly undone." The realistic picture of this occurrence was followed by another of an even more tragic kind, which was also taken from an early seventeenth century tract. The title of the picture, which appeared to need considerable explanation, was lengthy, and ran: — "News from Penrin (Penrhyn) in Cornwall of a most bloody and unexampled Murther, very lately committed by a Father on his own sonne (who was lately returned from the Indyes) at the instigation of a merciless stepmother, together with their most wretched endes, being all performed in the month of September last, anno 1618." The son, according to the additional details furnished by the letterpress, had returned to his father's house without saying who he was, and had been murdered in the night for the sake of his money. His grasping relatives did no long survive him, for remorse drove them to suicide. It was such incidents as these, which formed the staple attractions of the news-sheets of the time.

A new development arose with the appearance of the first regularly published illustrated paper, the *Mercurius Civicus*, which introduced portraits, including one of Charles I. and his Queen, and another of the Lord Mayor of 1643, Isaac Pennington. It was the *Mercurius Civicus* which introduced the bad precedent of publishing as an authentic representation of the man of the moment, any convenient portrait which happened to be at hand. The *Mercurius Civicus* was founded in 1643, and the illustrated newspaper might be said to have become firmly established in 1650, and to have made steady progress during the next century. In the eighteenth century, it sometimes utilised distinguished artists as illustrators. The heading of the *Jacobite Journal* which Mr. Thomas threw on the screen was, for example, attributed to Hogarth; and towards the end of the century, the *Observer* began occasionally to introduce pictures of current scenes, and events of popular interest. A very interesting one was that of Mr. Gurney's new steam carriage, the prehistoric motor car as it might be called, which was exhibited in Regent's-park. The staid *Times* followed suit on great occasions, and the day after Nelson's funeral, in 1806, published a very good view of the funeral car. Most interesting

also were the illustrations of the Cato-street Conspiracy which the *Observer* published, and which included up-to-date representations of the exterior of the Cato-street house, and the interior of the bomb itself. With the rise of the *Illustrated London News*, the first paper in which the drawings were the predominant feature, illustrated journalism took an entirely new position. The paper was founded by Herbert Ingram, and, still conducted by an Ingram, its editorship has remained in the family for three generations. Much of its earlier success was due to the drawings of Mr. (afterwards Sir) John Gilbert, a fine drawing from whose pencil, the opening of Parliament by Queen Victoria in 1846, was shown on the screen. The *Illustrated London News* was followed by *The Graphic*, founded in 1869 by Mr. W. L. Thomas, and this in its turn was followed by the *Daily Graphic*, whose initiative in publishing every day pictures of the previous day's occurrences, was constantly finding fresh imitators among the daily newspapers of all countries.

Having sketched the rise and progress of the newspaper which published illustrations, Mr. Thomas went on to describe, with many illustrations of drawings actually made and afterwards reproduced, the work of the artist and the artist-correspondent in gleaning his material and despatching it to the office of the paper where it would be reproduced, either in the form in which it was received, or developed so as to make it suitable for reproduction. One drawing shown was that of a Macedonian insurgent hurling a bomb, a subject which by its nature did not invite the artist who made it to linger longer in the neighbourhood than was sufficient for a very rough sketch; another was that of the act which won for Captain Smyth the V.C. at the battle of Khartoum in 1898. The first of these sketches was "redrawn" in a London studio; the second was "finished" by the artist, Mr. W. Maud, at the seat of war. The camera and the photographer sometimes took the place of the artist and his pencil, and each had their diverse uses and advantages. A snapshot of General Kuropatkin and his staff watching the battle of Liao-yang was rightly and effectively the complement of a drawing made by the artist (Mr. Whiting) of the general aspect of the battle. Each picture had its special interest from the other. Similarly two other snapshots, one of which showed the balloon accident that befell the aeronaut M. Severo, and the other the sinking of H.M.S. *Victoria* by the *Camperdown* in 1893, had a tragic and realistic interest which no drawing, however artistic, would possess. There were other examples in which by its ability to produce an effect of realism, or of irrefutable occurrence, the camera had the advantage over the artist, just as there were many instances where the artist by correcting the confused, or indistinct, or insufficient impressions of the camera could convert an uninteresting photograph into a true and lively picture of what actually occurred.

From the making of sketches and photographs, Mr. Thomas turned to their despatch. He described the sending of drawings from Paris (many of the originals of which lined the walls of the meeting-room) during the siege. They were sent by balloons, some of which were brought down by rockets or projectiles as they floated across the German lines, some were followed and captured by light cavalry, and one actually drifted to Norway. These sketches, despatched with such zeal and under circumstances of such difficulty, conveyed an impression of Paris during the horrors of the siege that was unsurpassable in its realism. There were, however, many difficulties encountered since then, which if overcome in a less ingenious way, called for no less energy and determination, and there were the drawings sent out from Mafeking by General (then Colonel) Baden-Powell, which were brought south by runner and eventually found their way to the *Graphic*. One of these showed the boys of the Cadet Corps which Lord Edward Cecil organised during the siege; another the children playing "Siege Games"; another the men in the trenches throwing bombs by means of sticks; and yet another the Mafeking trenches just at the time when the seventieth shell was bursting after a long day's attack. "So little damage," said the accompanying letterpress, "was done that the Boers became quite disgusted after firing 1,500 94-pounder shells and withdrew the guns altogether." In another part of Africa, during the last Soudan compaign, the *Graphic* artist sent his letters and telegrams down the Nile by native swimmers. These amateur postmen floated sixty miles down stream on logs and delivered their post with faithful regularity. The difficulties were hardly less great, and the methods of surmounting them hardly less ingenious in the present war in Manchuria, where, as the *Graphic* artist has pictorially shown, warnings are posted up everywhere to forbid sketching or photographing without permission.

Finally, after describing the postal methods and facilities in England, Mr. Thomas described the first steps which were taken to deal with the drawing when it reached the office in order to fit it for reproduction and printing. It was first of all photographed through a screen. The screen consisted of two sheets of glass on which finely ruled parallel lines were drawn, and these were fastened together so that the lines, at right angles to one another, made a network of tiny squares. The drawing, correctly focussed through the lined screen, was impressed on the negative behind it, and its image was thus broken up, as it were, by the meshes of the screen into arrangements of stippled dots, close together where the drawing was dark, and far apart where the drawing was light. Next, a piece of polished copper was coated with sensitized glue which, when exposed to light, became hardened. This was pressed in contact with the negative, and was exposed to strong light. The parts which had not been exposed to the light washed off on development in warm water. In other words, the light parts being soft, were washed away, and the dark remained. The plate then had dark and light assemblages of dots corresponding to those of the photographic negative. When the plate thus covered with dots had been made, it was then put into an acid bath, which bit away the spaces between the dots, leaving them in high relief. If the plate were now inked, the tops of the dots would be quite black while the lower surface were white; and that was the whole secret of turning a drawing into a plate from which prints could be made.

The second lecture will be delivered on Wednesday next, the 11th inst., at 5 p.m.

INDIAN SECTION.

Thursday afternoon, December 8th. Sir Charles H. T. Crosthwaite, K.C.S.I., Member of Council for India, in the chair.

The Chairman deplored the event which had caused him to be asked to take the Chair that afternoon. They all must regret the sudden death of Lord Hardwicke, a man of great promise and courage, who, if he had lived, would have taken a high place among the public men of the country. The Chairman then introduced Sir Frederic Fryer. When, in 1887, he (the Chairman) went to Burma as Chief Commissioner, Sir Frederic was Commissioner of one of the largest divisions in the upper province, to which he had come from the Punjab with the reputation of an active and able frontier officer. He maintained and increased his reputation all the time he was in Burma, and after he (the Chairman) had left, Sir Frederic became Chief Commissioner and eventually Lieutenant-Governor. He came before them that afternoon with 17 years' experience of Burma.

The paper read was—

BURMA.

By Sir Frederic Fryer, K.C.S.I.

Physical Features.

The province of Burma stretches along the whole sea-line of the eastern side of the Bay of Bengal. It is bounded on the east and north-east by China; on the north-west by Bengal, Assam, and the Manipur State; on the west and south by the sea; to the south-east lies the kingdom of Siam. The total area, including the Shan States, Chin Hills, and Karenni, has been estimated at 238,738 square miles. The area of Burma proper is about 168,573 square miles, of the Chin Hills some 10,250 square miles, and of the Shan States, which comprise the whole of the eastern portion of the province, some 59,965 square miles. The extreme length of the province is 1,200 miles, and its extreme width is 575 miles. The population is 10,489,024, according to the last census.

Burma is watered by five great rivers, of which the principal is the Irawadi, known to the Burmans as the Ayawadi or Father of Waters. Burma is encircled on three sides by a wall of mountains—the Arakan Hills, the Chin Hills, the Kachin, Shan, and Karen Hills. The most fertile tract in Burma is the Irawadi delta, a flat, alluvial plain, of a most uninteresting character, 12,000 square miles in area, where vast crops of paddy are grown.

The People of Burma: their Religion and Customs.

The people are described by Sir Arthur Phayre, in his "History of Burma," as a union of Mongoloid tribes, who have been considerably influenced by immigrations of Aryans. The Burmans, however, still maintain their distinct nationality. Their language and dress are peculiar to themselves. So also are their laws. They follow the Buddhist religion, and in appearance and physique are quite dissimilar to the Aryans. Though

the Burmans are Buddhists, they have a great respect for spirits, and were, no doubt, Animists before they were converted to the religion of Buddha. In every village shrine are found local "Nats" or spirits. Some "Nats" are evil and some good. In either case it is well to keep on good terms with them, and whether good or bad they have to be propitiated. Burmans, too, have a thorough belief in charms. They believe that a man may be made proof from bullet, sword, or drowning.

I remember finding a man in jail, who had been sentenced to a long term of imprisonment for killing another man. He told me that he had cut off a man's arm, and the man had bled to death. He explained that the man said he had a charm against sword cuts, and had challenged him to cut him with a sword. He accordingly did so, and was much surprised at the result, as he had no idea that the sword would injure the man. The story told me was, I found, quite true, and I remitted the man's sentence. In another case, which came to my notice, a Burman who had what he thought a charm against drowning, asked to have his arms and legs tied, and then got his friends to throw him out of a boat into the river. The natural result was that he was drowned.

There is no caste among Burmans, and they mix freely with those of other religions. They are exceedingly hospitable, and in all but the very smallest jungle villages there is a guest-house, where any stranger can rest himself and be supplied with food by the villagers.

There is no such thing as seclusion of women, and women mix freely in society. They are consulted in all matters of importance, and most of the petty trade of Burma is carried on by women. When a Burman visits an English officer he is generally accompanied by his wife, and often brings his daughters too, if he has any.

Education is very general amongst Burmans, as in every village there is an elementary school kept by the monk or monks, who teach the boys of the village. It is very rare to find a Burman who cannot at least read and write.

Burmans are naturally kind. They are very fond of children. They also treat their animals well. Burman ponies and cattle are always in good condition. Burmans never milk their cows, as they think it wrong to deprive calves of their natural sustenance. It is only when Burmans are excited that they become cruel. They are all fatalists, and face death with equanimity. It might be thought that they would make good soldiers, but in this they fail, owing to their want of any habits of discipline. The Burman has often been tried as a soldier, but the result has always been failure.

Burmans are cheerful, gay and laughter-loving. They are fond of gay colours, and the women, dressed in bright colours, with flowers in their hair, are very attractive. They are very fond of theatrical performances, which are often very long. The principal roles are those of Prince and Princess, and there is always a clown or two. Shouts of laughter at the clowns' jokes are frequent.

History of Burma.

The advance of the British power in Burma has been very gradual. Our knowledge of the country in the years previous to the first Burmese war is derived from the accounts of travellers, and from the reports of the many officers who from time to time visited Burma in charge of embassies to the King of Burma. In 1695, Messrs. Fleetwood and Sealey visited Ava on a mission from the Governor of Madras, and from that time till the first war was declared against Burma in 1824 there were frequent missions to the court of the King of Burma, to all of which the King behaved in a more or less arrogant manner, generally considering it beneath his dignity to receive the ambassadors sent by governors who were themselves subjects of the kings of England.

The first Burmese war was due to the encroachments of King Hpagyidoa on our borders in Chittagong and to his invasion of Kachar. As a result of this first Burmese war the province of Arakan, the districts of Tavoy and Mergui, and that part of the Tenasserim province which lies to the east of the Salween river, were annexed to the British dominions in February, 1826. The Kubo Valley was also made over to Manipur. The town of Maulmein was then rebuilt and became the headquarters station of the province of Tenasserim, which it still continues to be. In 1830, the Kubo Valley was restored to Burma at the intercession of Colonel Burney, the first Resident at the Court of Ava, an annual payment being guaranteed by the British Government to the Raja of Manipur, as an equivalent for the loss of the valley. Arakan was at that time administered by the Commissioner of Chittagong, under the orders of the Governor-General, as Governor of Bengal, whilst the

Tenasserim province was administered under the direct orders of the Governor-General in the latter capacity.

The second Burmese war was due to the refusal of the then King of Burma to be bound by the Treaty of Yandabo, which terminated the first Burmese war, and as a result of that war the province of Pegu became part of the British dominions, and the whole of Lower Burma up to Prome was lost to the King of Burma. The second Burmese war was determined by the Governor-General's proclamation of the 20th of December, 1852, annexing the province of Pegu. In 1853 the whole of Lower Burma, except the provinces of Martaban and Tenasserim, was placed under one Commissioner, with his headquarters at Rangoon. The province of Martaban consisted of the tract between the Salween and Tsitgoung rivers up to Rouk Pha Wa, west of the Panloung mountains, and was placed under the Commissioner of Tenasserim. In 1862, the whole of Lower Burma was united into one province, under a Chief Commissioner, Sir Arthur Phayre. It was not till 1885 that, owing to disputes with King Thebaw, war was for the third time declared with Burma, with the result that the King was deported to India, and in 1886 the remaining territories of the King of Burma were annexed to Great Britain. From 1886 to 1897 the whole of Burma was administered by the Chief Commissioner. On the 1st of May, 1897, the province was raised to a Lieutenant-Governorship, and a Legislative Council for the purpose of making laws and regulations was constituted. The number of members of council is nine, of whom four are ordinarily non-officials, and the Lieutenant-Governor is President of the Council. The Members of Council are nominated by the Lieutenant-Governor.

Pacification of Upper Burma.

The state of things now prevailing in Burma is very different from what it was when I first went to Burma in August, 1886, as a commissioner in Upper Burma.

At that time it may safely be said that armed opposition to our rule prevailed throughout Upper Burma, except in the capital, Mandalay, and in those parts of the country which were dominated by our troops. This was a result in great part of the anarchy which had prevailed in the last years of Burman rule, and also, in a measure, of the number of armed men who had dispersed over the country after its occupation. In King Thebaw's time it had been usual for each local governor to countenance the existence in the tracts of country ruled over by him of bands of armed marauders, whose misdeeds he overlooked on the simple condition that they confined their depredations to the jurisdictions of other governors than those under whose protection they lived. These marauders preyed on their own countrymen, and though, after annexation, they waged a guerilla war against the British, still they never ceased to plunder and murder their fellow subjects, and can in no way be regarded as patriots.

It was only by putting out a large number of military and police posts, by establishing roads, and maintaining constant communication by patrols between the different posts, by clearing away the dense jungle in which these men found a refuge, and by persistently disarming the villagers, that any head could be made against the disturbers of the peace. Very much was gained from the mutual dissensions of the so-called dacoit leaders, but the measure to which the rapid pacification of Upper Burma may principally be attributed was the Upper Burma Village Regulation, No. XIV., of 1887. The object of this measure was to restore and enforce the system of village responsibility which had formerly existed in Burma, but which had long fallen into disuse.

This Regulation very greatly strengthened the hands of district officers, and villagers found that they could no longer harbour and abet dacoits with impunity.

Before the Regulation was passed, it was a village saying that the sword of the dacoit was sharp, whilst that of the Government was blunt, that is to say, that any information given to the Government regarding the dacoits was generally followed by sharp and stern retribution, whilst villagers, who kept in with the dacoits, had little to fear from the Government. When the country people knew that the Government could, and would, protect them, whilst any collusion with dacoits would be punished, they began to find it to their interest to side with the supporters of the law, and with the aid of the people thus secured there was little difficulty in clearing the country of its oppressors, more especially as pardon was freely given to all dacoits who had not been guilty of heinous crimes on condition of surrendering their arms and living peaceably in future.

To facilitate the carrying out of the Village Regulation, all villages were required to stock-

ade themselves, and the residents of villages not in a position to defend themselves were required to move temporarily into the larger and stronger villages.

So rapidly did the pacification of Upper Burma proceed owing to these measures, and to the ample force of military and police placed in the field to support them, that at the close of the first five years of our administration of Upper Burma violent crime in the upper province was less than in the lower province.

In dealing with Burma, it must be remembered that the national crime of Burma is gang robbery with violence, and that no Burman is thought any the worse of by his countrymen because he is a dacoit. Burmans are an excitable race, and fond of anything which relieves the ordinary monotony of life. The nature of the country, too, with its dense jungles, lends itself readily to a robber's life. Burmans do not adhere to the tenets of their religion, which is most tenacious of the sanctity of life. If violent crime is still too rife in Burma there is little other crime, and though dacoity is certainly not a desirable form of crime, still, if some allowance be made for national idiosyncracies, we should not wonder so much at the difficulty experienced by British officers in Burma in repressing a crime which is no more looked upon with horror by the Burman than some forms of murder are by the Biloch, and most forms of murder by the Pathan.

Frontier Questions in Burma.

When the pacification of Burma had been accomplished the Government turned its attention to frontier questions.

We found the Shan States in a state of anarchy. Six of the rulers had rebelled against the authority of King Thebaw. We began the work of subduing the Shan States in 1887, and all the chiefs had submitted by the end of 1888. We entered the Chin Hills in 1888, but it was not until 1896 that the Chins were effectually disarmed, and even then they managed to obtain fresh arms, and the disarmament had to be carried out again in 1898.

The Kachins of the Bhamo and Myitkyina district were a great deal more difficult to deal with, and 1903 was the first year in which they gave no trouble. The Shan States, the Chin Hills, and the Kachin Hills are each administered under their own regulations. The Shan States are divided into the Northern and Southern States, each under a separate superintendent.

The Revenue System.

Having now told you something of Burma in general, I will proceed to give a short sketch of the revenue system of Burma, which differs much from what we have been accustomed to in India.

When I first went to Burma the unit of the revenue system was in Lower Burma the circle, and in Upper Burma the village. Each circle or village had a headman or Thugyi. In Lower Burma groups of villages had been united into circles, and the original idea of a village headman had been lost sight of. The Thugyi or headman was a revenue collector and little else. Now as Thugyis in Lower Burma have died out or retired, the village headman has been restored, and the circle headman is rapidly disappearing. The village will now, therefore, be the unit throughout Burma. The restoration of the village system, under responsible village headman, was one of the reforms inaugurated by Sir Charles Crosthwaite.

In Burmese times, in Lower Burma a rough calculation was made of the cultivated land in each village, and a rate per acre was levied on the area supposed to be cultivated. Besides this, one-tenth of the produce of each plough was taken in kind, and there were all sorts of other taxes, such as import and transit duties, monopolies, and forced contributions from time to time. In 1798, for instance, the king levied a forced contribution of six lakhs of rupees, and this operation was repeated whenever the royal exchequer needed replenishing.

In Upper Burma, before annexation, the main source of revenue was a tax called Thathameda, from a Sanskrit word signifying one-tenth. Each household was required to pay one-tenth part of its estimated annual income to the Crown. The whole village was held jointly responsible for the payment of this tenth, which was assessed according to the number of households. The amount to be paid by each village was settled according to the means of each household by a village council selected by the community and called Thamadis. No revenue was levied from private lands, but from State lands, which consisted of the King's private property, constantly added to by confiscations of the property of State offenders and by royal marriages, revenue was levied in kind, or by a commutation of pay-

ments in kind for payments in cash. Parts of the State domains were assigned to members of the Royal Family and to high officials, generally for life, and they were allowed to make what they could out of them. The tenants of State lands had no permanency of tenure and were constantly liable to be ejected in favour of other tenants offering higher rents or when the estate changed hands. The royal domains included all islands in the river and all forests and uncultivated lands.

In Lower Burma, when Arakan was annexed, the villages were first farmed out to the Thugyi, but in 1828 the revenue was fixed summarily for each village, and the Thugyi were allowed 10 per cent. commission on the revenue for the trouble of collecting it. The Thugyis still receive commission on their collections all over Burma, calculated at a rate which varies according to the amount collected, but not exceeding 10 per cent.

In the Tenasserim province, an average account of the produce of each village was taken at annexation, and a revenue was fixed by assuming 1-5th of the produce to be the Government share. Besides this there was a capitation tax of Rs. 5 on married men and Rs. 2·8 on bachelors, which is still levied throughout Lower Burma, except in certain towns where a land rate has been imposed in lieu of capitation tax. In 1842, these different systems were done away with, and revenue commenced to be levied by fixed rates according to the description of cultivated land. These rates are the only thing fixed about the land revenue in Lower Burma, and for the purpose of bringing new cultivation under assessment and remitting assessment on lands which have fallen out of cultivation, annual surveys are made in all districts which have been regularly settled by the Supplementary Survey Department, which is under the Director of Land Records. Any person wishing to retain his land, although he has thrown it out of cultivation, can do so for five years by paying a fallow rate. In districts, now very few, which have not come under settlement, the supplementary survey work is supposed to be done by the Thugyis. If any man desires to reclaim waste lands he can apply for a period of exemption from assessment, and this is granted according to the nature of the land to be cleared and the labour likely to be required, to clear it.

In Upper Burma the Thathameda system has undergone several variations. It has been decided to assess all private lands. The rate of assessment is to be three-fourths of that on State lands. The rates are fixed either according to the class of soil or to the description of crop grown. Revenue will only be levied on crops which come to maturity in both State and non-State lands. A crop which comes to maturity has been defined as any crop in excess of one-fourth of an average crop. District officers have, however, been authorised to modify this definition to an extent which, while conforming to the general principle, will adapt it to local conditions. The Thathameda, in districts in which it has been decided to assess private lands, has been adjusted on the assumption that the thamadis or assessors will assess those who derive no part of their income from agriculture at full rates—Rs. 10 or more, and the agriculturists at lower rates—Rs. 5 to Rs. 3, to which the average thathameda rate has been reduced or even less.

In certain districts such as Katha, the Ruby Mines, Myitkyina, and Bhamo, it has been decided to abolish the distinction between State and non-State land, on the ground that no such distinction has hitherto been recognised, and that no promise to grant differential rates has been made by the Government.

It has been contended by some authorities that the distinction between State and non-State land is purely artificial, and should never have been recognised. There can, however, be no doubt that it was recognised for several years before annexation, and that when Upper Burma came under British rule land known as non-State was not assessed or was assessed at favourable rates, as compared with State land. Whether the Burmese Government would have maintained the distinction, had it suited them to abolish it, may well be doubted.

The distinction is, of course, very inconvenient, and it necessitates two sets of rates of assessment, and as all waste land is State, any extensions of non-State holdings into waste land are liable to be separately assessed, which will add considerably to the cost of supplementary survey in the upper province.

In the "ya" or dry up-lands of Upper Burma, in which the rates of assessment are very low, the distinction between the two classes of land has been ignored, as to differentiate would be endless trouble, and the extra revenue that might be obtained is not worth consideration. The practical result is that State lands have been assessed at non-State rates.

The changes of system enumerated have been embodied in the Upper Burma Land and Revenue Regulation by an amending Regulation V. of 1901.

In every district it must be decided whether an abatement from the rates fixed on soil or crops shall be made before these rates are applied to the assessment of land other than State. The previous sanction of the Governor-General in Council is necessary to any decision on this point.

The whole of Lower Burma, with the exception of the unsurveyed districts of Salween and the Northern Arakan hill tracts and Tavoy and Mergui and a few other districts, has been regularly settled. Five districts in Upper Burma have been regularly settled, and two are under settlement. The usual term of settlement is 15 years in Lower Burma, and 10 years in Upper Burma, where things are still in a rather fluid state from a revenue point of view.

The total area cropped in Burma in the year 1902-1903 was 11,355,614 acres, and the area occupied but left fallow was 2,892,605 acres. The total land revenue was Rs. 19,832,883.

The peculiarity of the land revenue system of Lower Burma, as distinguishing it from the system in force in Northern India, is that in Lower Burma the rates of assessment alone are fixed, whilst in Northern India the revenue of each village is settled for a term of years. During that term no account is taken of land freshly brought under cultivation, nor is any reduction ordinarily given for land thrown out of cultivation, though in cases of calamity of season, or some exceptional destruction of crops, suspensions or remissions may be given. These cases are, however, not considered at settlement, but are the subject of special rules.

Again, the Lower Burma system differs both from that of India and that of Upper Burma in that there is no joint responsibility of village communities for either the land revenue or the capitation tax in Lower Burma. Each person from whom revenue is due is responsible for the amount at which he is assessed and no more.

Crops Cultivated in Burma.

Rice is the crop to which most attention is paid in Lower Burma. In Lower Burma six-sevenths of the total area under cultivation is devoted to rice. It is sown in June, transplanted in September, and reaped in December or January. The soil of Lower Burma is so rich that no manure is needed except the ashes of the stubble, which is annually burnt. In Upper Burma the rainfall is much less than in the lower province, and much more uncertain, so that rice is generally grown only in irrigated land. Maize, millets, sessamum, gram, wheat, tobacco, cotton, beans, peas, mustard, and indigo, are all grown in Upper Burma. In Lower Burma other crops than rice are little grown, and wheat is not grown at all, and cotton in most districts only to a small extent except in the Thayetmyo district.

In 1902-1903, 1,423,000 tons of rice were exported from Burma between the 1st January and the 30th June, and this export was much below the normal.

Cotton grows in the dry zone, chiefly in the Thayetmyo, Minbu, Meiktila, Myingyan, Sagaing, and Chindwin districts. The soil and climate of the Mandalay district, in which a canal has been constructed by the Government, and of the Shwebo district, in which a canal has been nearly completed by the Government, should be very suitable to the growth of cotton, and this staple might, I think, be introduced in these districts on a large scale. There are steam cotton presses at Allanmyo, in the Thayetmyo district, and at Myingyan. At present, most of the surplus cotton grown in Burma is exported to China. The census returns of 1901 show 136,628 women and girls employed as cotton weavers in Burma, and there are many more who follow cotton weaving as a subsidiary employment. Tobacco, which everybody, man, woman, and child uses in Burma, might be much more extensively grown. At present, the method of curing tobacco is not properly known, and large quantities of the leaf, which might easily be grown in Burma, are imported from India. An attempt was made in the eighties to improve the method of tobacco cultivation in Lower Burma, and an experimental tobacco plantation was started under a Government officer. This attempt was abandoned. Tobacco seed is, however, still distributed, and in the Thingwa district good tobacco is grown from imported seed.

Irrigation in Burma.

It may be said that Burma comprises two wet zones and an intermediate dry zone.

The lower wet zone comprises the greater part of Lower Burma. The districts of Prome, the upper-half of Tharrawaddy, and Thayetmyo, at the north of Lower Burma, have

a smaller rainfall than the rest of Lower Burma.

The lower wet zone enjoys a heavy rainfall, owing to its proximity to the sea. The central dry zone has a scanty and uncertain rainfall, as the excess rain clouds from the lower wet zone vaporise in passage over this zone and discharge themselves in the upper wet zone, which consists of the northern-most districts of Upper Burma.

In the wet zones irrigation is unnecessary, except in the upper districts of the lower wet zone, where irrigation would be most beneficial. The rainfall from the Pegu Hills might be utilised, were it not that the streams from the hills come down in torrents, bringing down large quantities of silt and sand, and are consequently most difficult to control. For this reason, any irrigation projects that have been examined in these districts have been considered not to promise sufficiently good financial results to justify their being undertaken.

In the dry zone proper there are perennial streams or rivers from which canals can be constructed at a moderate expense. The Burmese Government was alive to the utility of canals in this dry zone, and when we took over Upper Burma, we found several canals and irrigation tanks in Upper Burma. There were four canals in the Mandalay district, one in the Shwebo district, thirteen in the Kyaukse district, and two in the Minbu district. There were also a good many tanks. The principal tanks were the Meiktila Lake, the Nyaungyan-Minhla tank, in the Meiktila district, the Kyankse and the Yamethin tanks in the Yamethin district, and the Kanna tank in the Mynigyan district. There were also many minor tanks.

All those works have been repaired and remodelled by us, and we have also constructed the Mandalay Canal, 40 miles in length, which obtains its supply of water from the Madaya River. This canal has 14 distributions. It cost 47½ lakhs of rupees, and will irrigate 200,000 acres. It was opened by me as Lieutenant-Governor in January, 1902. A canal in the Shwebo district, 27½ miles long, with two branches 29 and 20 miles long respectively, is in course of construction. The estimated cost is 48 lakhs of rupees, and it will irrigate 258,658 acres. This canal is three-fourths finished. The Mon canals in the Minbu district, to irrigate 78,575 acres, have been commenced. They are estimated to cost 44 lakhs of rupees.

Besides these works, a good many tanks were constructed in the Yamethin and Meiktila districts, in the scarcity year of 1896. These tanks are not of much use, as in years of good rainfall they are not needed, and in years of scanty rainfall they remain empty. They are of service only in years of moderate rainfall, when they hold up a certain amount of water which is very useful at the end of the rainy season, when the rains cease unusually early. Whilst on this subject, it should be mentioned that two navigation canals, the Pegu-Sittang and the Sittang Kyaikto, were constructed in Lower Burma before 1886. They were intended to obviate the hazards of navigation by sea round the Gulf of Martaban. They are exceedingly useful, and have also drained large areas which would otherwise be water-logged. There is also a navigation canal between the Twanté and Kanaingto creeks 11½ miles long.

Numerous embankments have been made in the delta of the Irawadi River to protect cultivation from floods. These are very remunerative works, and return a considerable interest on the outlay incurred upon them.

The following is a list of the embankments, and of the percentage they return on the capital outlay:—

	Returns.
Irawadi (Kyangin)	1·64
Western (Myanaung)	6·66
Series (Henzada)	41·93
Thongwa Island	17·28

They have brought large areas of land under cultivation. Other embankments are in contemplation.

Communications.

A very important point in the development of a country is that there should be good communications. The splendid waterways of Burma have been taken full advantage of. The Irawadi Flotilla Company have a large and excellent fleet of river steamers. They ply on the Irawadi and Chindwin and Bassein and Tenasserim rivers, and their branches. There is a service of the Arakan Flotilla Company in the Arakan division, which, though on a smaller scale, is very useful. There are very few metalled roads, only 1,678 miles in all Burma. It is true that roads are not so much wanted in Burma as in other countries, as there is good communication by water, by rivers, and creeks in the rains, especially in Lower Burma. There are also 7,903 miles of unmetalled roads. Unmetalled roads are of

little use in the rains, and they are not much wanted in the dry weather when carts can travel across the fields. Bridges over nullahs and water courses are, however, indispensable. Feeder roads leading to the railway are also most necessary. At annexation there were only 327 miles of railway in Burma. Now there are 1,342.

The first line opened was Rangoon to Prome (161 miles) in 1877, and then no progress was made with railways till 1885, when a line 166 miles long was opened to Toungoo. This line was continued to Mandalay (220 miles) and opened in 1889, and was of much help in the pacification of the upper province. It gave employment to the people and opened out what was, perhaps, the most disturbed portion of Upper Burma. Since then the following lines have been added:—

Mu Valley—331 miles—opened at intervals between 1891 and 1899.

Thazi-Myingyan—70 miles—opened to Meiktila in 1895 and to Myingyan in 1899.

This line runs through a country where a great deal of cotton is grown. The earthwork was constructed mostly in 1896, when there was much scarcity in the Meiktila, Myingyan, and Yamethin districts, owing to the failure of the rains, and proved a most excellent method of employing the people.

Sagaing-Alon—70 miles—in 1896. This line avoids a long detour by steamer between Myinmu and Alon on the Chindwin River.

Myohoung to Lashio (177 miles).

This is the Mandalay-Kunlon Railway, of which so much has been heard, and is intended to be carried on some day into China.

This line was a very expensive one and it does not pay anything like its working expenses. It cost Rs. 129,556 per mile, whilst the average cost of railways in Burma calculated, or all the sections taken together, is Rs. 89,000.

Bassein to Henzada and on to Letpadan on the Prome line—115 miles.

Then there are over 32 miles of sidings or minor branches, including 62 miles of double line.

The Rangoon to Prome line pays 10 per cent. on the capital expended on it. The Rangoon to Mandalay line earns from 7 to 8 per cent.

The Mu Valley line does not pay yet, but when the Shwebo Canal is opened, and when there is sufficient rolling stock to work the line properly, it will certainly do so. The branch lines are doing fairly well, and a very great deal is expected from the Bassein-Henzada line.

The Mandalay-Lashio line, will not, I fear, prove remunerative for many years. Two new lines, the Pegu-Moulmein (120 miles) and the Henzada-Kyangin (65 miles) have been sanctioned. There is still a great deal to be done in the way of opening out Burma by rail. There is, of course, the suggestion that Burma should be joined with India by rail which will, no doubt, be carried out some day.

A line to open out the Southern Shan States is very urgently needed, and there are many feeder lines which it would be advantageous to construct.

Then a bridge over the Irawadi river at Sagaing is, in my opinion, greatly to be desired, and the lines to Prome and to Mandalay should be doubled.

FORESTS.

The value of the forests of Burma has long been recognised. The most valuable forest tree is the teak (*Tectona grandis*). It is a mistake to suppose that there are any pure teak forests. The teak tree is found sprinkled either singly or in groups, intermingled with many other kinds of forest trees. There is said to be generally about 10 per cent. only of teak in a forest, and there are, says Dr. Nisbet, lately a conservator of forests in Burma, about 150 different genera and species of forest trees to be found in each several forest. These form an overwood to dense masses of bamboo and undergrowths often 30 ft. to 60 ft. in height, and sometimes shooting up to 100 ft. or more when able to obtain free enjoyment of light. Much damage was done to the forests in which teak occurs by indiscriminate felling in the early days of our administration, particularly in the Tenasserim forests.

The teak tree has always been a royal tree in Burma, and no private person has ever been allowed to fell a teak tree, even though growing on his own land, without a licence. The property of the Government in teak trees being universally admitted, it has been the policy of the Government gradually to reserve all forests in which teak is found in any quantity, and there are now nearly 20,000 acres of reserved forest in Burma. This area is being gradually increased year by year as the Forest Department are able to examine more and more forests. Although the teak tree is a royal tree there are, as I have said, many other trees and much undergrowth in a forest, and in most of the forests the neighbouring villagers

have acquired rights which have to be carefully enquired into. Sometimes, when they are insignificant, they are bought out, but ordinarily they are met by leaving a sufficient portion of the area to meet the wants of the right holders outside the boundaries of the reserve.

The extraction of timber is partly done by contractors, under the immediate control of the Forest Department, and partly by lessees, but no tree may be extracted that has not been girdled by the Government forest officers. Besides the teak there are numerous other trees, which are reserved with the object, principally, of protecting them from destruction. There are about fifteen different reserved trees. One of the most valuable is the cutch tree (*Acacia catechu*), which grows abundantly in the central dry zone. The cutch wood is chipped up and boiled, and yields a rich dark-brown dye.

Then there is the india-rubber tree (*Ficus elastica*). This tree is indigenous in the dense moist sub-tropical forest to the north of Myitkyina, Mogaung, and Indavgyi, and in the upper portion of the area drained by the Chindwin River.

It is collected by Kachins, who sell it to Chinese traders. The produce of india-rubber is rapidly declining owing to indiscriminate tapping, and particularly to the tapping of the roots, which kills the tree.

These india-rubber forests are in the unadministered area, and nothing has yet been done to conserve them. Major Wyllie, when cantonment magistrate of Rangoon, planted a few acres at Kokine, near Rangoon, with india-rubber trees, and his plantation promised very well. Now Government have commenced the planting of 10,000 acres on King's Island, near Mergui, with india-rubber, with a view to show what can be done with inda-rubber in Burma, and in order to induce private persons or syndicates to form further plantations of rubber. There is an experimental garden near Mergui where rubber has been proved to thrive, and for this reason a plantation was formed near Mergui.

The net forest revenue of Burma in 1902-1903 was Rs. 37,74,509. The total export of teak in that year was 229,570 tons, of an average value of Rs. 88,52 per ton.

The Forest Department in Burma is under-handed and might be very considerably increased with great advantage to the administration of the forests, and also, I am persuaded, with much benefit to the forest revenue.

Fire protection is very essential to the conservation of forests. Over 5,000 acres of forests were successfully protected from fire in 1901-1902. Improvement in felling, to encourage the reproduction of teak, and the formation of teak and cutch plantations, are among the important tasks of the Forest Department. The people find employment in these plantations, which gives them an interest in preserving them from fire.

Excise and Opium.

There is nothing peculiar in the administration of the Excise in Burma. Distilleries are owned by private firms, who are required to maintain an Excise officer on their premises. No shop for the sale of liquor or opium can be established without the consent of the inhabitants of the locality.

The use of opium by Burmans is prohibited, except to persons who were above 25 years of age before the 1st of February, 1893, and who registered themselves as habitual consumers. The prohibition of the use of opium by Burmans is, no doubt, a wise measure. The use of opium is contrary to the Buddhist religion, and the drug is very deleterious to Burmans, who are prone to exceed in its use when once they have formed the opium habit. The use of both opium and spirituous liquor was nominally forbidden to Burmans in Upper Burma in the time of the Burman monarchy, and we have continued the prohibition, and done our best to make it effectual. In Lower Burma we do not prevent Burmans from using spirituous liquor, and the consequence is rather anomalous. A Burman may buy spirituous liquors at, say, a refreshment-room on the railway in Lower Burma, but not when the train has passed the boundary into Upper Burma.

Opium is forbidden for Burmans, except to those who hold a certificate allowing them to use it, in both Lower and Upper Burma. The prohibition against the use of intoxicants is very difficult to enforce, especially in the case of opium, which is of small bulk, and is easily concealed. The facilities for smuggling opium are very great. There is a long line of frontier, and the numerous passes and waterways offer great facilities to smugglers. Opium can be and is introduced from China, the Shan States, Siam, and the Kachin Hills, and from adjacent districts in Bengal. The consumption of opium in limited quantities by Chinese and other foreigners, who use it with more moderation than the Burmans, is allowed. The

Chinese say that they cannot maintain their health in malarious climates without taking opium, and they are so habituated to its use that they insist on getting it by foul means if they cannot get it by fair means.

In 1873 rules were introduced by which the right to deal in opium was sold by auction to retail vendors, who were allowed to sell a fixed amount calculated on the number of known opium consumers in the area of each shop. The retail licences were nearly always bought by Chinamen, and there was no doubt that they increased their supply of the drug by smuggling, and that opium was hawked about freely all over the country.

The small number of shops, and their distance from the homes of the consumers, gave a premium to smuggling. It was, therefore, decided that a change in the system of opium administration was needed, and with a view to kill the illicit traffic and to render prohibition effectual, the sale of opium licences by auction was abolished from the 1st of April, 1902, in Lower Burma, and from the 1st of April, 1904, in Upper Burma.

The sale of opium has now been entrusted to selected vendors at a fixed fee, and the sales are made under Government supervision.

The number of shops has been increased so as to bring the drug within reach of those entitled to use it. The Excise staff has been very largely increased, and there is now a resident Excise officer in each shop. It is believed that the result of these measures has been a distinct check to the contraband trade, owing to the displacement of illicit opium by Government opium sold to authorised consumers at licensed shops, but that the measure has not been altogether successful in restricting the use of opium and in keeping it out of the hands of non-registered Burmans. An opportunity was given to those who had failed to register themselves as opium consumers in 1893, to come forward and do so. This opportunity was taken little advantage of, and this is not much to be wondered at, as opium consumers are much looked down upon by orthodox Buddhists, and to register himself as an opium consumer is looked upon by a Burman much as to register himself as an habitual drunkard would be looked upon by an Englishman.

The opium revenue suffered somewhat by these new measures; but, even if it had suffered more, there would be no hesitation in incurring loss of revenue if the object of the opium regulations could be attained.

The total revenue from Excise and opium in 1902 and 1903 was Rs. 29,01,045. The use of hemp drugs is prohibited throughout Burma, and their importation into Burma is also prohibited. The prohibition is frequently evaded by Indians who are accustomed to use this drug. Ganja or hemp is used medicinally for elephants, and a supply for this purpose is always obtainable from confiscations.

Salt Manufacture.

Another much contested question is the manufacture of salt in Burma. At present the idea is to tax salt of local manufacture at the same rate as imported salt, viz., at one rupee per maund of 82 lbs. Salt is manufactured in both Lower and Upper Burma. In Lower Burma it is for the most part made along the sea coast by evaporation from salt water, and in Upper Burma it is manufactured from brine obtained from natural salt springs. About 5,500 families are engaged in salt manufacture, and prohibition of the manufacture of salt in Burma would throw these families out of employ, at all events for a time. If salt of local manufacture can be so taxed as to give it no undue advantage in competing with imported salt, the manufacture of this salt would not be injurious to the revenue. The great difficulty is to find a means of taxing this local salt which will prevent the manufacture of more salt than the Excise assessments cover.

Up to 1902 the custom had been to levy a duty on the vessels employed in the manufacture of salt calculated on the quantity of salt each vessel is estimated to produce. In 1902, in certain prescribed areas, free licences to manufacture salt were issued and the salt so manufactured had to be stored and duty was leviable only when the salt was sold. The salt boilers at first refused to work on these terms, but now they have been accepted in two districts, and, if the experiment proves successful, the new system will be generally adopted. Of salt imported into Burma, 60 per cent. came from Germany.

Salt is largely used in the preparation of "Ngapi," which is a preparation of fish largely used by Burmans; indeed, "Ngapi" is a daily article of diet with Burmans.

The fishery revenue of Burma is very large. In 1902-1903 it brought in Rs.28,38,846. The whole question of fisheries has been reported upon lately by a special officer, Major Maxwell, who takes great interest in the subject, and many of his recommendations for the improved

management of the fisheries have been adopted.

Mines and Minerals.

There is no doubt that Burma contains considerable quantities of minerals. The minerals worked at present are petroleum, rubies, gold, tourmaline, jade, amber, mica, steatite, tin, lead, and silver. There are other minerals, such as iron, plumbago, and antimony, and probably, as the development of the country proceeds, much mineral wealth will be discovered.

The most valuable mineral worked now is petroleum. There is petroleum in the Akyab and Kyaukpya district of the Arakan division, but it has not been found in paying quantities, though it has been worked for years.

In Upper Burma there are large petroleum fields at Yenangyoung and Yenangyat, in the Magwe and Minbu districts, and petroleum has been found at Singu, to the North of the Yenangyoung fields in the Myingyan district. The Government duty on petroleum is eight annas (eightpence) per 100 viss, which equals 365 lbs.

The depth of the oil wells worked by Europeans on the Canadian principle is usually from 200 to 300 feet, but some are very much deeper. Petroleum is worked by the natives in a primitive manner with shallow wells worked by hand.

The Burma Oil Company have two large refineries, one at Rangoon and the other at Syriam, which is a little below Rangoon on the river.

The company also own tank steamers in which it is sent to India in bulk. There are smaller refineries owned by other companies at Yenangyat. The oil of Yenangyoung is rich in paraffin wax. The royalty on petroleum in 1902-1903 amounted to 8 lakhs of rupees, and the petroleum industry is well established and increasing.

The ruby industry is leased to the Ruby Mines Company, and is proving remunerative. In July, 1902, the mines were flooded by heavy rain, but this year the company has declared a dividend of 15 per cent. A new lease has lately been granted to the Ruby Mines Company, which should encourage them to invest more capital in the undertaking. The mines are at Mogok in the ruby mines district.

Rubies in small quantities are found in the Myitkyina district in the extreme north of Burma, where they are worked by Chinamen, and at Sagayin in the Mandalay district in the marble quarries. Jade and amber are found in the Myitkyina district. Gold was found in the Katha district, where a company was formed to work it. The reef on which the company was working has been exhausted. Another company is dredging for gold on the Irawadi river above Myitkyina, and is meeting with success. Companies have, I understand, been formed to dredge for gold on the Chindwin river and on the Sittang river near Shwegyin. Gold is washed by the natives on the Chindwin and Sittang river and also on Uyu river, which is an affluent of the Chindwin. Shortly after annexation the people on the Uyu river paid in their revenue in gold.

The Burma Coal Company work coal at Letkokbin in the Shwebo district. The coal is not of very good quality and the difficulties of transport are much in the way of the company. The coal has to be carried to the river some six or eight miles distant by tramway and then sent to Mandalay by flats belonging to the Irawadi Flotilla Company, and there placed on railway trucks. The only customer for the coal is the railway company, and the coal suffers much from frequent handling. The mines might be connected with the Mu Valley railway by a short branch line about 20 miles long if the capital to build the line could be found.

There is an excellent coal-field on the Chindwin river, another at Lashio on the Mandalay-Kunlon line which the railway company contemplate working. There is also coal in the Tenasserim division, at Thayetmyo, and at different places in the Shan States.

Tin is found in the Tavoy and Mergui districts of the Tenasserim division, where it has been worked for years by Chinamen. A company is also working tin in the Mergui district. Previous companies formed to work tin have not been successful.

Tourmaline is worked in the ruby mines district, steatite in the Pakokko and Minbu districts, silver and lead in the Southern Shan States. The working of mica in the ruby mine district has been abandoned. The want of sufficient labour is much felt in mining enterprises. The Burmese population is sparse, and, where a living can easily be got from the land, there is no great attraction to work in the mines. Cultivable land is abundant, and anybody who can provide the small capital to buy plough cattle and the necessary agriculturural implements can break up waste land, which he can take up under a few simple rules

Burmans, particularly in Lower Burma, are well-to-do. They live and dress well, and can afford to spend money on pagodas and festivals. The Burman is not given to saving, and, when he has put by a little money, he takes a holiday to spend it. He does not think of using his capital to make more or of making provision for his family.

Taxation in Upper Burma was much heavier in the time of the monarchy than taxation in Lower Burma, and the people were not so well off. The rainfall in Upper Burma is more precarious and the crops in the upper province are sometimes a failure. Upper Burmans, therefore, often migrate to Lower Burma to work in the rice-fields and to help in getting in the harvests. Many of them take up land and remain in Lower Burma. Employers of labour in Burma have, therefore, to depend mostly on imported labour, which can be obtained from India or China. Imported labour is expensive, and imported labourers often desert for more remunerative undertakings. There have been a good many schemes for importing the surplus population of congested districts in India to Burma. They have generally been failures. The only one that has had any measure of success is that of Mr. Milne. This gentleman was granted 30,000 acres of land in the Shwegyin district of Lower Burma. He brought over settlers from Behar, from, I believe, his own estates there. He supplied the settlers with all they required until they had broken up land and made themselves self-supporting. He gave much personal attention to the scheme and spent a good deal of money on it, and above all he had influence over the settlers who had relations on Mr. Milne's Behar estates. It will be some years before the settlement will commence to repay the money expended upon it, but the experiment promises to succeed. Under an arrangement with the Government of Bengal immigrants from Behar and Chotia Nagpur can get a free passage to Burma, but not many have availed themselves of this privilege, and, until there is direct communication by rail between India and Burma, no large influx of Indians into Burma is to be expected.

Large numbers of coolies come from Madras every year to work in the rice mills and in the fields, but the great majority return to their homes at the end of the season, and only a small residuum remains in Burma. A good many military policemen, principally Gurkhas, marry Burmese wives and settle in Burma. They find ready employment in keeping dairies, which the Burmans never do, and are sometimes found in the most out-of-the-way places. In spite of all this labour is scarce in Burma, and is likely to remain so for many years.

It will, I think, be a bad day for Burma if ever the easy-going, laughter-loving Burmans are elbowed out of their own country by thrifty and pushing Chinamen and natives of India.

Conclusion.

In what I have said about Burma I have endeavoured to give a brief account of Burma, showing how the country has gradually come under British rule, what is the character of the country and its people, what the laws and customs of the country are, and what our system of administration has been.

Considering that no part of Burma was under British rule before 1826 it may, I think, be claimed that the country has amply repaid our efforts to bring it under settled administration and to secure its progress and development, and the happiness and content of its people.

My difficulty in dealing with the subject has been how to condense the matter before me within reasonable bounds, and in my endeavours to be brief I have omitted a good deal which I might have said had it not been for my fear of wearying my audience. As it is, whilst I have not, perhaps, escaped from being tedious, I trust I have succeeded in giving you some idea of what a valuable acquisition Burma has been to the British crown.

Great progress has been made since the country came under British rule. To take over a country, which had hitherto been administered in the roughest and readiest manner, and to apply to it all the methods of civilised Government, must always be an arduous undertaking.

When we took over Upper Burma, we had to equip it, as we had previously to equip Lower Burma, with every kind of building needed for civilised administration. Courts of law, police stations, post offices, telegraph lines and offices, barracks, jails, were all wanting, and there were no proper houses for officers. All these have been or are being supplied. There is still something left to be done both in Upper and Lower Burma. For instance, the increase of cultivation, population, and revenue in the delta of Lower Burma, have made it necessary to add another district to the Irawadi division, in spite of the fact that an additional district had already been created ten years ago. Then the work of the civil officers

has so increased in Lower Burma that a separate judicial service is now found to be required as executive, revenue, and judicial work can no longer be carried out by single officers. All this means additional expenditure. Fortunately, the revenues of Burma have hitherto constantly increased from year to year, and with the large area of cultivable waste, which is being gradually brought under the plough there is no immediate chance that the limit of expansion of revenue will soon be reached.

Burma seems to me to offer a very favourable field for the investment of capital, and as the country becomes better known more and more capital will, I feel sure, be attracted to it. In any case trade must increase, and, so far as I can foresee, the prosperity of Burma is likely to continue undiminished.

If nothing else could be said for British administration in Burma, it may be at least asserted that the condition of the people has been improved under our rule. There has been a considerable advance in the market price of produce, and in many districts, where the rates were settled some years ago, the people have had the full advantage of this advance. Statistics show that the indebtedness of the people is on the increase, but this is, I take it, not any indication of poverty, but it is due partly to the fact that Burmans are naturally extravagant, and partly to the fact that they have borrowed money in order to increase the area of their cultivation. Grants of waste land are keenly competed for.

There has never been any general scarcity in Burma. There was scarcity in three districts of Upper Burma in 1896-7, but even in that year 18,000 people were the maximum employed at one time on famine works. The food supply of the province is greatly in excess of the needs of the people and there is always a large surplus available for export. The wages of labourers show a constant tendency to increase, and pauperism is practically unkown.

The number of tourists who visit Burma is steadily increasing, and to those who have not visited Burma may be strongly recommended to do so. There is beautiful scenery, an interesting people willing to welcome visitors, large and small game shooting for those who can find time to enjoy it, archæological remains to be studied, and those who are in the fortunate position of having capital to invest might easily do so to their profit in Burma.

There is a great field for an agricultural bank (similar to the Agricultural Bank of Egypt) in Burma, and many other openings might be found for the employment of capital in Burma; 24 per cent. is now readily paid for loans to agriculturists on good security, and the development of the country is much retarded by the scarcity of capital.

The climate is, of course, not suitable to European settlers. In Lower Burma, March, April, and May are dry and hot. In the rains it is not so hot except when the rains hold off for a day or two, but it is very damp. November, December, January, and February are the pleasantest months, but even in those months it is seldom cold. In Upper Burma, the climate is much drier. It is very hot in the summer, but much colder from November to March. In the hills, the climate is more bearable.

Before bringing this paper to a close, I should like to allude briefly to a recent suggestion that Burma should be separated from India, and made a Crown colony, being united with the Straits Settlements and Ceylon. The relations of Burma with the Straits Settlements and Ceylon are very slight, whilst she draws her army, her covenanted Civil Service, her Indian Marine vessels, her military police, and a great part of her labour from India. Burma was conquered by India at a great expense of men and money, and has hitherto been administered from India.

Her laws are mainly adapted from those in force in India, and there is next to nothing in the Burma system of administration which conforms with those in force in the Straits Settlements or Ceylon. It is true that I have observed that the development of railways in Burma suffers from the fact that Burma has to share with other provinces of India in the distribution of the capital available for railway construction, but, I think, that a plan might easily be desired whereby Burma would obtain financial control of her own railways, and that, in this manner, she might be able to accelerate the opening out of her resources by means of new railways. Burma, it must be remembered, is a new province, and requires a larger expenditure upon railways, communications, and public works in general, than the older provinces of India.

Besides this the frontier policy of Burma has, hitherto, been directed from India and, so far as I have been able to judge, it has been directed with great efficiency and, if Burma became a Crown colony, her frontier policy is so interwoven with that of India, that India would still have to exercise a pre-

dominant voice in all political questions affecting Burma. In case of trouble in Burma or on her frontiers, it is to India that she would have to look for assistance.

In my opinion, Burma would lose a good deal more than she would gain by being separated from India even if she were constituted a separate Crown colony, and I can see nothing that she could gain by being united to the Straits Settlements or to Ceylon.

It is urged that the Straits Settlements and Ceylon have prospered greatly as Crown colonies. Burma, too, has made great progress as a province of India—Upper Burma was only annexed in 1886, and was then in a state of anarchy. For some years all the energies of Government were devoted to the pacification of the province, and it was only when this task was accomplished that attention could be given to commercial and industrial progress. Since peace was secured Burma has certainly not stood still, and I have every confidence that the progress of Burma as a province of India will continue to be rapid enough to satisfy her most ardent well-wishers. I doubt myself whether the people of Burma have any unanimous wish to be separated from India, and I do not see how the separation could be accomplished without injury to the province, as it would involve a complete change in more than one direction.

DISCUSSION.

The CHAIRMAN said that they were all very much obliged to Sir Frederic Fryer for the very interesting paper he had read. If anyone wished to know more about Burma he would recommend two books, one being "The Burman," by Shway Yoe, the *nom-de-plume* of Sir George Scott, which was one of the best works that had been written about any country. The other book was "The Soul of a People," by a well-known officer of the Burma Commission; it gave a most charming account of the Burmans, their religion, and their feelings; rather, he thought, from too rosy a point of view, but still, it was full of kindliness and grace and well worth reading. The main characteristic of the Burman was his instability. He was a devil-may-care fellow who gave no thought for the future and very little for the present. That was why they had never been able to make him a good soldier. They had been able to get from the natives of other countries a contingent for the Army, but it was impossible to impress upon the Burman any such sense of duty as was required as an elementary part of a soldier's business. He remembered one case where they tried to raise a military police composed of Burmans, but they had to give the idea up. A Burman was put on sentry, and he would say to the first man that came along, "Take hold of my musket and keep it while I go to the theatre, and I will give you a sixpence." That spirit prevailed throughout the whole of the country, but at the same time they were most charming people, and the country was delightful in many ways, except for the extremely damp heat. There were also the mosquitoes, which would prevent anyone from falling into too sound a slumber. When he was at Rangoon some of the ladies used to put their feet into large mosquito bags and tie them up during dinner, otherwise they could not have existed for a moment without fidgeting about and feeling exceedingly uncomfortable. A Burma mosquito could get through a mosquito curtain as easily as a burglar could enter an unprotected window. However, those were minor things in a splendid country, a country that was prospering and would continue to prosper more and more. One reason for that was there was a large and enterprising mercantile community of Englishmen and Scotsmen, with a strong contingent of Germans, now in Rangoon, and they were the real force to push the country on. The Government was there mainly to keep order and secure fair play. He himself should like to see a communication opened between Burma and China. Many people had laughed at him for advocating this, but he had never lost sight of the possibility of opening up railway communication between Burma and Yunnan, and until that was done he did not believe that they would reap the full fruit of their enterprise in Burma. If a careful survey of the country, which had not yet been made, showed the scheme to be impossible, then, of course, they must put up with what they had, but he hoped that sometime or other, the project would be carried out. He thought that when Lord Dalhousie in the second Burma war extended our frontier up to Thayetmyo, he had some hope that there would be a great commerce coming down the Irawadi Valley, not only from the upper parts o Burma, but from China. The Chairman concluded by expressing his great pleasure at having been able to welcome Sir Frederic Fryer that afternoon and to hear that the Burma which he left 14 years ago was very much the same now as then.

Mr. JOHN HALLIDAY, as an old Anglo-Burman, observed that what he had to say must take the form of thanks for Sir Frederic Fryer's very painstaking and unvarnished account of the province which he had so long and successfully governed. They must all thank him for continuing to take an interest in that province, and he (the speaker) hoped Sir Frederic would continue to do so for many years to come. The author's story of the man who was drowned reminded him of a similar incident. When he was in Bassein a man was bound hand and foot and tied up in a mat and then pushed off the pier into deep water. They waited some time and there was

no sign of him, and although he (the speaker) was a magistrate and justice of the peace, he thought he would be tried for abetting murder, and pictured himself dangling at the end of a rope. He broke into a cold sweat and turned away, but to his great joy when he got to the end of the pier the "drowned" man was running along the bank. With regard to the proposal to disconnect Burma from India, he thought it was a crazy idea. Burma had made great progress hitherto and there was no reason why it should not continue to do so. It had the pick of the Bengal civil servants for its officials, its commissioners and lieutenant-governors, and from his experience of close on 50 years he should say leave well alone. With regard to the railway at Lashio, it was stated that it did not pay, but no line in the same condition would pay. They had made the railway to end nowhere. The London and Brighton Railway would be in the same position if it ended at Hayward's Heath. If they carried the railway into Yunnan and down to the Yangtse, he had not the least doubt that, in the course of time, it would be a very large concern. Unfortunately, the present Viceroy had rather set himself against the idea, and they must wait till he came home before they could do anything. On behalf of the audience, the people of Burma, and himself, he thanked Sir Frederic for his able paper.

Dr. John Pollen, C.I.E., said it might possibly be asked what could a Bombay man know about Burma. He thought Bombay men knew a good deal more than they sometimes got credit for. At any rate, he did know something about Burma, and he knew much more about it than he did before that evening, after listening to the admirable paper. He was certainly in a better position than the Member of Parliament who, meeting an officer who had just returned from fighting in Burma, asked him about the country, and then said, "I always heard it pronounced Bermuda." His (Dr. Pollen's) own knowledge of Burma commenced very early, in 1874, when he was summoned with other Bombay officers to save the perishing millions of Bengal from famine. He had had a good deal to do with Burma rice and colossal cash advances. His next experience was when he had, should he call it, the privilege of acting as quasi-gaoler to King Thebaw, on which occasion he also made the acquaintance of the Queens whom they had seen on the screen that afternoon. King Thebaw was much finer-looking than the picture shown represented him to be. The only troublesome member of the party was the old Queen Mother. He remembered her very distinctly. When he had met other Indian Queens, they had always been very carefully wrapped up in muslins, and concealed behind curtains, but this lady was distinguished by an absence of such drapery. She insisted on an interview with him, and in the most impassioned language, which he could not understand, she denounced, as he was afterwards informed, the Government of India for their meanness and shabbiness in not providing her with a carriage. She thought it was a great shame that she was obliged to petition her son to lend her his carriage. The last he saw of the King was about two and a half years ago, and he thought Sir Frederic Fryer would be interested to know that Thebaw's education was being advanced, and that he now spoke English fluently. He told him (the speaker) in very good English that he was certain he was a far happier man cultivating his little garden at Rutnagherry, than he ever would have been if he had been allowed to remain ruler of the Burmans; so the British Government had not done him a bad turn in depriving him of the responsible office he once held. He (Dr. Pollen) also had the honour of conducting a representative of Burma at the time of the Coronation, and he was then privileged to learn a little more of the manners and customs of the Burmans, and altogether his experience induced him to form a very high opinion indeed of their character. They certainly knew how to take things very easily, but while making themselves happy they endeavoured to make others happy also.

Mr. Martin Wood said that consequent on the annexation of Upper Burma, the expenditure increased by many millions in the following years. Had the large excess of income over expenditure that British Burma previously boasted of, by this time made up for cost of the conquest?

Sir Frederic Fryer said he understood that last year the revenue of Burma exceeded the expenditure by about two millions sterling.

On the motion of the Chairman, a vote of thanks to the author was carried unanimously.

CANTOR LECTURES.

MUSICAL WIND INSTRUMENTS.

By D. J. Blaikley.

Lecture III.—Delivered December 12th, 1904.

I propose connecting the subject of the last lecture, "Brass Instruments," with that before us this evening, which is "Reed Instruments," by some experiments showing the presence of partial tones in notes produced from examples of each class. Partial tones may be either harmonic or inharmonic, but at present we need only consider those which are harmonic, or stand related to the prime tone (which gives the name to the note) by their vibrational periods being in arithmetical progression of whole numbers. In most distinctly musical qualities of tone, these partials are heard up to the sixth or eighth; in some qualities much higher partials, even up to the sixteenth or

twentieth, can be detected, and in some, the even numbered partials are either altogether absent, or very weak. This latter condition arises in instruments like the clarinet, the peculiarity in the proportions of which will presently be described.

By means of resonators, or tubes adjusted to the pitch of the partials which may exist in a compound tone, such a tone can be analysed. I have here a few resonators which, in this case, are tubes adjustable in length, and closed at one end with diaphragms of gold-beater's skin. Against each diaphragm or drumhead a small bead is suspended, and the disturbance of this bead shows that the resonator is answering to a vibration in its neighbourhood. This vibration may in its wave form stand for a simple or prime tone, or may be but one component of a complex wave form, isolated by the resonator from the general mass of tone.

[Experiments with resonators.]

Such experiments as these prove that the compound character of musical tones is not a mere scientific theory, useful as a working hypothesis, but is a matter capable of very direct proof.

In these experiments I have somewhat anticipated matters which should properly have come under consideration later in the evening, but the difficulty of keeping the resonators tuned in an atmosphere varying in temperature and moisture must be my excuse.

Reed instruments fall under two main divisions, as will be seen by reference to the Table of Classification, according to the type of reed used, which may be either double or single. We wlll throw on the screen representations of both. The double reed, seen in elevation and also foreshortened, that the space between the two blades may be seen, belongs to the bassoon, and represents also the principle of the oboe reed. The single reed fitted to a mouthpiece is from a B flat clarinet: the saxophone has a similar reed, but its mouthpiece differs somewhat from that of the clarinet. The general action is the same in every case. The air, being under some slight pressure in the player's mouth, is driven through the chink between the blades of the double reed, or between the single reed and its mouthpiece. As a steady, unvarying pressure on the reed cannot cause vibration but merely deflection, it is evident that the sum of the internal and external pressures upon the reed must vary in intensity.

Something of the action of a musical reed may be illustrated by the behaviour of a slip of wood under weights differently applied. This slip or lath of wood is clamped at one end, but its other end is free to move under certain conditions, and it may be taken to represent a clarinet reed. In its normal position it is at rest, and it is also at rest when loaded at its free end. This second condition represents the reed under pressure differing on its two sides, when the difference is unvarying. If the load is applied suddenly the slip vibrates, but ultimately, through molecular friction, and other causes, comes to rest in the second position. In the actual reed, the varying total pressure by which its vibration is maintained, is due to induced currents on the inner side, or side next the associated tube, the variation in the chink between the reed and the mouthpiece being the immediate cause of these.

Reeds very roughly produced suffice to give continuous tones, which may be fairly musical so long as they are confined to one note, or to a very limited range of notes, but for a reed to speak well over the great compass of some of our modern instruments, it must be fashioned with much care and delicacy.

The relationship between the natural pitch of the reed, *i.e.*, its own rate of vibration, and the pitch of the tube to which it is applied is worthy of some slight reference and examination. The question is sometimes asked, "Does the reed control the pitch of the air in the tube, or does the air control the pitch of the reed?" The correct answer is that they control each other: a strong reed controls the comparatively light mass of air in the tube, but the lighter and more delicate the reed the more it is itself controlled by the mass of air in the tube.

I have here a harmonium reed of metal with which tubes can be associated and their influence upon the speech of the reed manifested. The reed itself speaks at a pitch of about 1024, or an octave higher than our highest fork. Acted upon by the same wind is another reed slightly out of unison with it, so that beats between the two can be heard. We can make the first mentioned reed speak through a short length of tube fitted with a telescopic slide or cover to regulate its length, and you will notice that with changes of length the rapidity of the beats changes. This change of pitch is, however, not nearly so great as the corresponding change in the length of the tube, and the result obtained shows, therefore, that this metal reed can accommodate itself to a slight extent to the natural rate of vibration of the air in the

tube. Or to put the case another way, the air in the tube can be thrown by the reed into a forced vibration foreign to its natural period. There is, however, a limit to this, for with certain lengths of tube all sound ceases.

It might be imagined that the addition of tube, and a consequent addition to the mass of air to be thrown into vibration, could not improve matters, but this is not the case, for the condition to be obtained is one of sympathy between the reed and the resonating air column. As the experiment proceeds, you will notice that as lengths of tube corresponding to a quarter, three-quarter, and one and a-quarter wave-lengths are added to the length giving silence, speech is resumed, whereas when lengths agreeing with the half or whole length are added, silence is maintained.

The light cane reeds used for reed instruments adapt themselves much more readily than metal reeds to alterations in the natural pitch of the air column, but, out of the several notes possible from a given length of tube, the particular one required is obtained by the control of the lips over the reed, and we may regard the first great step in the artistic development of reed instruments to have been the removal of the reed from a mere air-chamber, and the placing it under the control of the lips. Mainly by this means the compass of an octave or so on the bagpipe chanter has been extended to a compass of between three and four octaves on the bassoon and clarinet.

Each of the main divisions of single and double reed instruments are further sub-divided into those with cylindrical and those with conical tubes.

As was remarked during the first lecture, the bagpipe drone may reasonably stand for the simplest type of single reed, and from the facility with which it can be cut, it is very possibly the oldest. It is, however, tolerably certain that both single and double reed instruments were in use in the earliest historical times. Here are copies of two Greek "flutes" now in the British Museum, which are really reed instruments, but whether single or double reed is somewhat uncertain.

The scale on all reed wind instruments is obtained by varying the length of the resonating air column by means of side-holes. The diatonic scale can be obtained by the cutting of six side-holes, closed by the fingers, which holes give (assuming the fundamental pitch to be C) *c*, *d*, *e*, *f*, *g*, *a* and *b* respectively, the sixth or *b* hole serving also when the other holes are closed to facilitate the production of the octave of the prime tone. Other octave notes can be produced on a conical instrument by varying the action of the lips on the reed, but semi-tones lying out of its normal scale are false or weak.

On our scheme of classification bagpipes are given as illustrating the family of enclosed reeds, or reeds uninfluenced by lip pressure. As these instruments are all supplied with wind delivered from a regulating bellows or reservoir, and not directly from the lungs, they stand on the limiting line which divides our subject from the organ class of instruments; indeed, Mr. Henri Lavoix, in his work, "La Musique au Siècle de Saint Louis," fitly describes the bagpipe as the organ reduced to its simplest expression. In one group of bagpipes the reservoir is supplied from the lungs, but, in the other, it is supplied from a small feeder worked by the arm; the Irish or Union pipes, and the Northumbrian pipes belong to this group, also the delicate musette, which was fashionable in the reign of Louis XIV., and was introduced into the orchestra by Sully. The most important member of the first group, at the present day, is the great Highland, or military bagpipe, which has a conical chanter, or melody pipe, played with a double reed, and three drones with single reeds, two of which are tuned in unison in A, and the third an octave lower. The scale of the chanter is peculiar, having its two minor thirds divided, not into a whole tone and a semi-tone, but into two intervals of three-quarters of a tone each. As this division is known in some Eastern scales, it is possible that the bagpipe chanter scale is Arabic in its origin.

The passing away of other once popular instruments, such as the cromornes, which were sounded by reeds enclosed in chambers, and therefore removed from the regulating power of the lips, appears to be due chiefly to their unsuitability for the rendering of really artistic music. At the present time, all reed instruments used in the orchestra have their reeds directly under the control of the lips of the player. The first family to be considered comprises oboes and bassoons: these are conical, double-reed instruments, having their proper tones in the harmonic series, 1, 2, 3, 4, &c. They are the modern representatives of the old schalmeys or shawms, bombardts, and pommers. The fingering of all these was based upon the six finger-hole scheme, and on the bass instruments one or two extra lower notes were obtained by the use of open-standing keys. It was noticed in speaking of the

general scale system, that the sixth hole could be used to facilitate the production of the octave of the prime tone. In the modern oboe, the successor of the discant schalmey or treble shawm, two very small holes are introduced above the sixth finger-hole; these are controlled by keys, and give certainty to the production of the upper harmonics, by preventing the establishment of nodes in their neighbourhood.

Although a few keys in addition to the finger-holes suffice to give a chromatic scale, in all modern work these are supplemented by many others, serving the following three purposes:—1st. The extension of the compass downwards: this extension in the oboe carries the pitch from D to B flat. 2nd. The production of shakes. 3rd. The production of many notes by alternative fingerings.

The downward extension of compass by means of keys is well seen on the bassoon. This instrument is an improvement on the old bass shawm or pommer, which was very cumbersome owing to its great length. The tube of the bassoon is doubled upon itself, and therefore the two thumbs can be brought into use to close holes lying below the six finger holes, and also to work keys which still further extend the compass downwards. By these means the lowest note of the bassoon, B flat, is two octaves below the lowest note of the oboe, although its general pitch is only a twelfth lower; for instance, with the three left-hand finger-holes closed the oboe gives G and the bassoon C, an octave and a fifth lower.

The cor-anglais is an instrument of the oboe type and characteristics, but one-fifth lower in pitch, and between this instrument and the ordinary oboe comes the oboe d'amore.

Instruments of the bassoon type have also been made in various keys, but the only variety of any importance is the double bassoon, or contra-fagotto, in pitch an octave lower than the bassoon proper.

These, the oboes and bassoons and their congeners, are the only double reed instruments now in use, and they are all conical tubes, overblowing to the octave, twelfth, &c. With the single reed instruments the case is different, for the most important of these, the clarinet, is an instrument with a cylindrical tube, expanding to a bell only at its mouth and overblowing to the twelfth.

The modern clarinet is derived from the chalumeau, a rude instrument made from a natural reed, in which a speaking tongue was cut near one end, and also six finger-holes and one thumb-hole. The distinctive feature of the clarinet as invented, or at least developed by Denner, is the use of one hole, covered by a key, both as a note-hole, and as a speaker to facilitate the overblowing to the twelfth, for, the clarinet having a cylindrical tube, the octave harmonic No. 2 is absent. The notes which cannot be obtained from the customary six finger-holes, even when supplemented by a seventh, or thumb-hole, are obtained by key-work, which is absolutely necessary on the simplest clarinet.

The most modern of the reed instruments is the saxophone, which has a conical tube, and a single reed and mouthpiece, very similar to those on the clarinet. The instrument was invented by Sax in 1840, and being conical, overblows to the octave, and in the general arrangement of its keys, is very similar to the oboe. Although but little known in this country, it holds an important place in the French military bands.

The lecture was illustrated by the following programme of music:—

Oboe solo, Concertino, *Guillhaut*, Mr. J. L. Fonteyne. Clarinet solo, Concertino, *Weber*, Mr. Charles Draper. Bassoon solo, Adagio from Concerto, *Mozart*, Mr. E. F. James. Trio: oboe, clarinet, and bassoon, *Huguenin*. At the pianoforte, Mr. R. H. Walthew.

RUBBER IN THE GOLD COAST.

The cause of the preparation of the Report,* by Mr. W. H. Johnston, the Director of Agriculture for the Gold Coast, with its supplementary historical note by Sir W. T. Thiselton Dyer (the Director of the Royal Botanic Gardens, Kew), and report by Mr. C. W. Smythe, the Curator of the Botanical Stations in Sierra Leone, is due to the extraordinary recent decline in the rubber exports of the Gold Coast. An industry which in 1899 exported goods valued at £555,731, and in 1903 exported only a value of £196,500, certainly called for investigation. As may be imagined from the reports from other rubber-producing countries, this has been due mainly to ruthless tapping by improvident natives, and to the tapping of immature trees. As a consequence, practically all the rubber plants have been exterminated from the coast to as far as a week or ten days' journey inland. The report therefore considers what steps should be taken to replant trees best adapted for cultivation in the colony, which will give a return on the expenditure initially incurred at as early a date as possible, at the same time yielding the

* "Colonial Office Reports," Miscellaneous, No. 28, 1904.

largest percentage of rubber of good quality. The probabilities of the six varieties generally considered as most valuable are carefully discussed. As has happened elsewhere, the *Castilloa elastica* is peculiarly susceptible to insect pests. The best results have been obtained from the *Funtumia elastica* and the *Hevea brasiliensis* varieties. Experiments at Aburi have proved that the former should not be tapped before its ninth year, then it will yield two ounces of dry rubber per tree. It is, however, susceptible to serious damage from the larvæ of a moth, known as the *Glyphodes ocellata*. Repeated applications of lime and ashes seem to be about the best methods of exterminating this pest. The *Hevea brasiliensis*, since its introduction into the colony, has been remarkably free from insect and fungus pests. Mr. Johnston and Mr. Smythe both concur in recommending this variety as yielding better results under cultivation than any other known plant. Four trees, ten years old, tapped for the first time in 1903, yielded 67 ounces of dry rubber, or 16¾ ounces apiece without showing signs of having suffered in the slightest degree. The heavy rainfall on the West Coast and rich soil are alike considered favourable. Mr. Smythe reports the Sierra Leone rubber industry as nearly dead, and unlikely ever to be revived, unless taken up in earnest by enterprising Europeans. From the natives who have so avariciously destroyed a valuable industry, little is to be hoped. On one occasion, Mr. Johnston caused some 15,000 rubber plants to be propagated at the Aburi Botanical Gardens, offering them free to native chiefs in the immediate neighbourhood. Only about one-tenth of these were accepted, and the remainder had to be planted out at Government expense in the Aburi and Kola plantations.

ART-TRADE SCHOOLS IN GERMANY.

As far back as the beginning of the nineteenth century instruction in art-trade drawing was inscribed upon the programme of the numerous industrial and polytechnic associations founded in Germany for the promotion of industrial development. But the aim was rather technical efficiency than artistic finish. The first object was the replacement of foreign manufactured goods by the products of home industries; and the instruction given was devoted principally to the inculcation of the mathematical, scientific, and commercial knowledge necessary for the progressive requirements of modern industrial life. Great attention was paid to accuracy in constructive drawing, and the adoption of new and improved methods of manufacture. Interest in art, the formation of taste, the production of wares not only technically perfect but combined with artistic finish were relegated to the second place. Nor is there anything surprising in this when the condition of the German States during the period following the Napoleonic wars is remembered. The reaction and exhaustion were so great, the lack of capital, and economic misfortune were so widespread, that few were in a position to embellish their homes and surroundings by the acquisition of artistically wrought goods. It was not until after the Great Exhibition of 1851 that the movement for the foundation of art-trade schools in Germany began, and they owed their inception and development to the desire to compete with France in the production of artistic wares, and the endeavour to succour handicrafts menaced by the general adoption of machinery, by gradually transforming them into art-trades. The United Kingdom was the first country to profit by the lessons of the Great Exhibition. The creation of the Department of Science and Art and the South Kensington Museum, mark the first systematic attempt to place the art-trade industries of the country upon an independent national basis, and to promote and control their development. Germany followed in the wake of Great Britain, but her art-trade schools and museums, founded during the latter half of the last century, whilst using British models to some extent, were shaped by the educational views prevailing in Germany, a distinguishing feature being the promotion of intimate relations between the aims of the schools and the needs of the local and district art-trade branches of industry.

The general aim of the art-trade schools in Germany, writes Dr. Rose, His Majesty's consul at Stuttgart, in his very interesting report on art-trade schools in Germany, just published ("Miscellaneous Series, Diplomatic and Consular Reports," No. 621), "is briefly the application of art to industry, the endeavour to impart the methods and develop the faculties for the utilisation of the graceful and harmonious in nature, in the production of the ordinary practical objects of trade and daily use. To durability and serviceability, the two cardinal principles necessary in the production of goods, are to be wedded grace of form and harmony of colour. The art-trade worker must not be a mere mechanical producer of useful wares, but must imbue his work with the sense of the beautiful drawn from the measure of his own talent and his contemplation and interpretation of the great book of nature." Dr. Rose says that the movement in Germany in favour of art-trade instruction is still in an experimental and tentative stage, and some time must yet elapse before anything like uniformity is attained in the methods of instruction, or unanimity arrived at regarding the cardinal principles of art involved in art-trade instruction. Taken as a whole the art-trade schools have not yet attained the efficiency of the technical schools. A weak point is the paucity of instruction workshops and the insufficient equipment and accommodation of those already installed, shortenings due to the lack of necessary funds and imperfect appreciation of the important *role* played by such workshops in art-trade instruction. Still the art-trade schools have beneficially influenced the art-trade products of Germany, and if these products continue to show much that is undesirable the explanation is to be found partly in manufacture solely for purposes of profit, and partly in the indifference of an indiscriminating public.

AUSTRALIAN RAILWAYS.*

In a country like Australia, in which are to be found immense districts untraversed by navigable rivers, railway construction becomes a pressing necessity for the purpose of providing a means of communication between the leading ports and the interior, but the limited population of the six federating States, barely four millions at the close of 1903, has precluded the idea of the work being conducted by private enterprise, although the earlier attempts were a result of individual effort. As the main object of Australian railway construction is to assist in opening up and developing the country, rather than providing dividends for shareholders, each of the State Governments has had to assume the responsibility of constructing its own railway system, for which purpose considerable sums of money have been borrowed, the total loan expenditure for that purpose to June 30, 1904, being £136,600,855. Practically, railway construction constitutes the leading item of Australian indebtedness: the loan expenditure on all other works, including telegraphs, telephones, water supply, sewerage, harbours, rivers, navigation, roads and bridges, public works and buildings, defence, &c., amounting to only £83,520,606. Nearly the whole of the Australian public debt, £227,637,163, unlike that of most other countries, has been expended in connection with railways and other public works, which, at the present time, represent a value several millions in excess of Australian public obligations. The various States may have borrowed somewhat freely, but they can show substantial security for every shilling of loan money obtained. In 1903-4, the total length of railways open for traffic in the Commonwealth was 14,464 miles, of which Victoria possessed 3,381 miles, New South Wales 3,362 miles, Queensland 3,030 miles, Western Australia 2,170 miles, South Australia 1,901 miles, and Tasmania 620 miles. The progress of construction has become increasingly rapid during each successive decade, which explains in some measure the frequency of recent borrowings. With the exception of 640½ miles constructed in connection with mining, timber-getting, and other industrial enterprises, the whole of the railways are the property of the respective State Governments. In New South Wales the State railways are placed in charge of three Commissioners, and of a single Commissioner in Victoria, South Australia, Queensland, and Western Australia, those of Tasmania being in the hands of a general manager, under the control of the State Minister for Lands and Works. Proposals for constructing a line from Adelaide, in South Australia, across the continent, to Port Darwin, in the extreme north, and from Adelaide to Western Australia, are under consideration. The latter line, if completed, would enable an almost unbroken journey from Brisbane, by way of Sydney, Melbourne, and Adelaide, to Western Australia, to become accomplished, but the gauges of the different States would have first to be made uniform. The total cost of construction and equipment of the various Government lines to June 30, 1904, was £131,930,764; the gross earnings in 1903-4 being £11,193,518, and the net earnings £4,065,631, thus producing a fair rate of interest on the amount of capital invested. The net earnings would have been considerably larger had the lines through several of the less populated districts been of a "pioneer" character. The greater portion of the railways are substantially built, and will endure for generations. In places engineering difficulties of considerable magnitude have been successfully overcome, especially in New South Wales, where the great cantilever bridge across the Hawkesbury is one of the largest and finest in existence. Compared with certain sparsely settled countries, the cost of railway construction in the Commonwealth has been remarkably low, being £9,890 per mile, as against £14,355 in Brazil, £12,810 in the United States, £12,067 in Canada, £10,363 in Cape Colony, £10,213 in the Argentine, £10,103 in Chili, and £9,417 in Mexico. At the same time the work has been of a more solid and durable character than in several of the countries mentioned. Considering the limited number of population, the Commonwealth railways are proportionately amongst the best-paying lines in the world, the average net revenue per train mile being 21·6d., against 25·0d. in the United Kingdom, 17·7d. in Belgium, and 29·5d. in the United States. The number of passengers carried in 1903-4 was 110,163,232, while the goods traffic showed a total of 14,985,106 tons. The rolling stock included 2,191 engines, 3,921 passenger carriages, and 41,918 goods trucks. In New South Wales the railways are divided into three systems, the south, running from Sydney across the Murray to Melbourne; west, from Sydney to Bourke; and north, from Sydney to Brisbane. In Victoria the lines form seven distinct groups, covering the State with a complete network of lines. In Queensland the railways constitute a number of separate systems, three of which have Brisbane for their centre, while others run inland from each of the principal ports. In South Australia the railways are divided into three systems, radiating from Adelaide, with the exception of a short line in the northern territory; in Western Australia the railways comprise five systems, connecting the larger centres of population; while in Tasmania, Hobart, Launceston, and other places are similarly linked together. These figures will afford some idea of what the federated States have done with the greater portion of their borrowed capital. They may have been somewhat hasty at times, but they have ample assets in the shape of their railways alone to meet all their obligations. The only fault that can be found with the State policy of the past, according to the New South Wales Government Statistician, "is that in some cases expensive lines have been laid down in empty conutry, the requirements of which could have been effectually met for many years to come by light and

* Communicated by Mr. John Plummer, Sydney.

cheap lines.'' Had this been done the net profits of the Commonwealth railways would have been largely increased.

CORRESPONDENCE.

THE PATENT LAWS.

The paper read before the Society on the Patent Laws and published in the *Journal* on the 16th Dec., will be much appreciated, especially by those interested in inventions and patents. Its appearance also is opportune. As a rule, inventors will not trouble to obtain a copy of the new Act of 1902, they naturally expect their patent agents to be thoroughly conversant with it, but when the information is picked up in the form as given out by the paper and the discussion, the knowledge is found to be very useful to the inventor. The writer and his father (the late Sydney Smith) have obtained for their inventions many patents, both British and foreign; the difficulty met by others in getting their claims through the German and United States Patent Offices have been felt by them. Some of the objections raised have been most frivolous, and the loss of time involved in amending and appealing serious, notwithstanding the applications being in the hands of able and experienced patent agents. Our firm considers the new Patent Act an improvement on the old. In the light of experience the Act will be best tested, and its value known.

It was a surprise that no one present at the meeting said a word or two in reply to the Chairman's remarks when he said, "It was easy to invent, there was nothing in that, but it was extremely difficult to introduce a new manufacture, and the people who did introduce new manufactures ought to be the people who were rewarded."

Those who have come in contact with inventors know that a majority of them are not pushing, enterprising, business men. That is not their sphere of work, that is not their forte.

It is unreasonable to expect an inventor who has spent large sums of money in experimental work, and sometimes years in brain labour, should at the same time possess business qualification for putting his invention on the market. In some instances this has been done; the cases are rare. A man may become a clever business man by training, but you cannot make an inventor by any such process. The faculty is born with him, sometimes hereditary, and in the science of machinery generally found in the mind of the practical mechanic. The factor that developes and exercises it most is necessity, which still remains the "mother of invention." The reward of a valuable and useful invention often goes to the keen, energetic, business people, while the obscure genius "'who gave it birth" receives but scant recognition or adequate remuneration, unless he be connected with a firm possessing the necessary capabilities for making the best of his patented invention. Instead of the prosperity of this country being principally attributed to the policy of free trade there is a deep and growing conviction in the country that much of the progress made belongs to that distinguished class named by Mr. Abel, and who by their successful inventions created industries and made England, at one time the workshop of the world.

ISAAC SMITH.
(Of Sydney Smith and Sons.)

Basford Brass Works, Nottingham.

OBITUARY.

FREDERICK ELKINGTON.—Mr. Elkington, who had been a member of the Society of Arts since 1859, died at his residence, Sion Hill, near Kidderminster, on Monday, 2nd inst., at the age of 78. He was the eldest son of Mr. George Richards Elkington, the patentee of electro-plating, and he was largely responsible for the development of the important firm bearing his name. He was made a Chevalier of the Legion of Honour in 1852, and on the occasion of the Paris Exhibition of 1885 he was promoted to be an officer of the Legion. In 1878 he served the office of High Sheriff of the County of Worcester and was a governor of the Imperial Institute. He was greatly interested in the Volunteer movement in Birmingham, and one of the first to join the force. A carriage accident, however, necessitated his retirement some years ago, when he was promoted to the rank of major. Apart from his commercial career, he rendered valuable service to art, and was an industrious and discriminating collector of Japanese and Chinese enamels.

GENERAL NOTES.

BRITISH GUIANA AND COTTON.—The annual report of the Department of Mines and Lands for the year ended March last comments on the comparative failure of the proposed revival of the cotton industry in the colony. The Berbice Cotton Growers' Association has been trying to interest the peasantry in the industry, but in spite of generous offers of assistance little has been done. At the date of the report only about four acres were in cultivation in cotton by peasant farmers. Nor is the outlook more promising, for, although there was money available for an exhibition in the present autumn, there were no exhibitors. Several of the plantations in Berbice are, at the request of the Association, giving cotton growing a fair trial, but the attempts must be regarded, says the

report, more in the light of practical object-lessons for the encouragement of the small farmers than indications of any serious idea on the part of the sugar planter to establish cotton growing as a complementary industry. Just now the prospects of the sugar industry are so bright that the planter will rather use every effort to put all available land in canes than detach labour to cultivate the pasture lands of his plantation with cotton. Moreover, the growth of the rice industry tends more and more to shorten the supply of labour.

IMPORTS AND EXPORTS.—The following figures are taken from a Table prepared by the Board of Trade, and showing the principal imports and exports of merchandise of the principal countries for which the particulars can be given up to September 30, 1904, inclusive, and referring in all cases to the same period, namely, the nine months ended September. The corresponding figures for 1902 and 1903 are added for the purpose of comparison:—

Imports (see Note that follows Tables).

	1902.	1903.	1904.
	£	£	£
United Kingdom	339,522,000	341,688,000	345,358,000
France	129,965,000	140,551,000	132,455,000
Germany	207,677,000	220,378,000	227,887,009
United States	146,281,000	150,083,000	156,537,000
British Indies	30,677,000	39,706,000	45,843,000
Japan	19,696,000	24,858,000	26,810,000

Value of *principal* articles only.

Exports (Domestic) see Note that follows Tables.

	1902.	1903.	1904.
	£	£	£
United Kingdom	209,501,000	217,379,000	221,189,000
France	124,021,010	125,219,000	127,561,000
Germany	171,262,000	184,161,000	187,424,000
United States	192,230,000	201,635,000	201,132,000
British India	62,795,000	71,860,000	77,899,000
Japan	17,863,000	20,810,000	22,133,000

Value of *principal* articles only.

The Board of Trade explains that in the case of the United Kingdom, France, Germany, and Japan the import figures represent imports for home consumption only, *i.e.*, excluding the re-exports. In all cases the export figures are intended to represent exports of domestic produce. In most cases, however, they include a certain amount of goods originally imported for consumption, and which, if dutiable, have been charged with duty, but which are subsequently re-exported. It will be noticed that Germany heads the list in absolute increase in exports, but British India comes in a very good second—£16,162,000 as against £15,104,000. The United Kingdom is third on the list with an increase of £11,688,000. Up to the date to which the figures carry the war had not affected the steady increase in Japan's exports.

THE CITY AND THE BOARD OF TRADE.—In July, 1897, the Board of Trade appointed a committee to consider and advise as to the best means of bringing to the knowledge of traders in this country the information furnished by consuls, commercial attachés, representatives of the colonies, and other officers, as to the supply and demand, and the conditions of the markets in their respective districts, and to report how far arrangements could be made for the exhibition of trade samples in London and in provincial trade centres. A year later, in July, 1898, the committee reported, and one of their principal suggestions was the creation of a Commercial Intelligence Branch of the Board of Trade. This suggestion was adopted and the branch opened in October, 1899. With a view to ensuring that the new branch shall be kept as far as possible in touch with all those interested in its efficiency, and in order to obtain advice of the widest possible scope upon questions of commercial interest, a consultative advisory committee was appointed in May, 1900. Four years later, in March, 1904, this committee reported upon its work and was able to show that the Intelligence Department was steadily growing in usefulness to the business community. In 1901 the applications for information numbered 1,614, in 1903 they had risen to 3,599. But the offices of the intelligence branch were at the West-end, and it is difficult to get the ordinary man to go far in search of information, so it was determined to move from 50, Parliament-street, to 73, Basinghall-street. This change to the centre of the City took place some months ago, and has now been tested sufficiently long to enable it to be said that it promises to be highly successful, there being already a sensible increase in the number of inquiries. The department cannot fail in its new habitation to be of great use to merchants' and traders' associations in search of accurate information on commercial matters in the interests of British trade.

EDUCATION IN THE STRAITS SETTLEMENTS.—Sir John Anderson's annual report for 1903, as Governor of the Straits Settlements, issued a week or two ago by the Colonial Office, contains some remarks concerning educational progress. Nearly all the schools in the colony are vernacular schools for Malays, under the direct control of the Government by whom all the expenses are defrayed. Free tuition in Malay is thus given to some 10,000 pupils. The remaining schools are, with the exception of two or three, which are controlled and financed directly by the Government, aided schools, managed by private bodies receiving Government grants in aid. In 2 schools only English is taught, in 5 English and Tamil, in 3 Tamil only, in 1 Chinese only, and 171 Malay only. The net Government expenditure

on aided schools (English, Anglo-Tamil, Tamil, and Chinese) was 53,087 dols., and on Government vernacular schools 75,128 dols. The sum of 12,376 dols. was also spent on the Malacca Training College for Malay teachers. The demand is in excess of the supply, and it will be some years before the vernacular schools are staffed exclusively with trained teachers. A training school for English teachers is still under contemplation. The principal English schools now have classes in commercial subjects.

THE ST. LOUIS EXHIBITION.—Although the stockholders will get nothing in the way of dividends, the receipts of the Louisana Purchase Exposition have been immense. No official final statement has yet been issued, but the following is a summary from safe sources of the receipts:—

	Dollars.
St. Louis city (free grant)	5,000,000
U.S. Congress (free grant)	5,000,000
St. Louis citizens (subscriptions)	5,000,000
U.S. Congress for exhibit......	1,488,000
Insular Government (Phillipine Islands)	500,000
State appropriations	6,000,000
Gate receipts (estimate)........	5,000,000
Concessions (25 per cent.)......	1,500,000
Foreign Governments	5,000,000
Value of exhibits (estimate) ..	11,000,000
	46,488,000

It is estimated that there were 5 000,000 visitors to the city during the exhibition. Suppose they averaged 15 dols. each spent in the city—a moderate estimate—that would mean that 75,000,000 dols. were circulated by the visitors during the seven months of the exhibition.

THE COTTON SUPPLY.—No one has been more identified with the movement of which the British Cotton-Growing Association is the outcome, than Sir Alfred Jones, and it is re-assuring to find him saying in a letter to *The Times* that the American bumper cotton crop for the current year will not check the efforts now being made to increase the supplies of cotton from within the Empire. He protests against the idea that "a big crop and 4d. will be the end of the British Cotton-Growing Association." American opinion seems to agree with him that the movement has now gone so far that it cannot be seriously affected by one big crop in the South, whatever might be the result of a succession of them. The present cotton crop of over 13,000,000 bales is the largest on record, and for the moment Lancashire has nothing to fear, but just as the home demand is shrinking the wheat exports of America, so the time may not be very distant when most of the raw cotton of the union will be worked up in American mills. By that time it is to be hoped the British requirements may be met by supplies from British territory, that the West Indies, the West Coast of Africa, the Sudan and Central Africa, India and Guiana may between them meet the deficiency. It is curious that of the estimated increased exports of cotton from America since September—about 400,000 bales—the Continent has taken less by 10,000 bales than during the like period of 1903. Nearly the whole of the increased export has come to England.

CHINESE AND INDIAN IMMIGRATION INTO THE STRAITS SETTLEMENTS.—The population of this Far Eastern possession is increasing rapidly by reason of immigration from China. These immigrants find a ready employment in tin-mining, and are really necessary to the successful development of the Malay Peninsula generally. Some rise to the position of contractors to the Public Works Department, others enter Government service, and make their way to high positions in the audit and other departments. The following are the figures of the Chinese immigration for the last four years:—

Year.	Male.	Female.	Total.
1900.........	188,985	11,982	200,947
1901.........	166,956	11,822	178,778
1902.........	194,005	13,151	207,156
1903.........	205,782	14,539	220,321

On the other hand, the total number of immigrants from British India was as follows:—1901, 28,259; 1902, 20,242; 1903, 22,033. Scarcity in India is evidently a dominant factor so far as the emigration of the Tamil coolie is concerned. While the Chinaman flourishes as a merchant, and drives about Singapore or Kwala Lumpur in a motor-car, the Tamil (who, according to officials in the Public Works Department, is deficient in stamina) makes his way back to Southern India as soon as his means permit.

THE WORLD'S MERCANTILE MARINE.—Recent statistics estimate the total tonnage of the world's merchant marine at 33,643,000 tons, and the number of vessels at 24,850, of which 12,671 are steamships with 27,184,000 tons, and 12,182 are sailing vessels with 6,459,000 tons. This gives an average of about 1,540 tons for steamers and 538 tons for sailing vessels. Although the construction of large ships has greatly developed during late years the greater part of the world's goods is still carried by vessels of average tonnage. The number of ships of over 10,000 tons is only 89. Of vessels over 5,000 tons the United Kingdom has 533, Germany 100, America 48, France 36, Russia 12, Japan 16, and the Netherlands 7. The tonnage of the principal countries is as follows:—United Kingdom, 16,006,374; America, 3,671,956; Germany, 3,283,247; Norway, 1,653,740; France, 1,622,016; Italy, 1,180,335; Russia, 809,648; Spain, 714,447; Japan, 726,818; Sweden, 721,116; Netherlands, 658,845; Denmark, 581,247; Austria-Hungary, 578,697; Greece, 378,199; Belgium, 157,047; Brazil, 155,086; Turkey, 154,494; Chile, 103,758; Portugal, 101,404; and Argentina, 95,780 tons.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock:—

JANUARY 18.—"Wireless Telegraphy and War Correspondence." By CAPTAIN LIONEL JAMES. SIR WILLIAM HENRY PREECE, K.C.B., F.R.S., will preside.

JANUARY 25.—"London Electric Railways." By the HON. ROBERT P. PORTER.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

JANUARY 19.—"The Gates of Tibet." By DOUGLAS W. FRESHFIELD. SIR WILLIAM LEE-WARNER, K.C.S.I., will preside.

COLONIAL SECTION.

Tuesday afternoons at 4.30 o'clock:—

JANUARY 24.—"British Commercial Prospects in the Far East." By BYRON BRENAN, C.M.G., late H.B.M. Consul-General at Shanghai. SIR EDWARD A. SASSOON, Bart., M.P., will preside.

APPLIED ART SECTION.

Tuesdays, at 4.30 or 8 o'clock:—

JANUARY 31, 8 p.m.—"Calligraphy and Illumination." Two Papers. By EDWARD JOHNSTON and GRAILY HEWITT. LEWIS FOREMAN DAY, Vice-President of the Society, will preside.

CANTOR LECTURES.

Monday evenings, at 8 o'clock:—

JAMES P. MAGINNIS, Assoc.M.Inst.C.E., M.Inst.Mech.E., "Reservoir, Stylographic, and Fountain Pens." Three Lectures.

LECTURE I.—JANUARY 23.—*Ancient Writing Implements.*—The Stylus and Tabula—Calamus or reed pen—Stencil—Quills, quill nibs, attempts to make quills more serviceable—Substitutes for quills—Silver pens—Ink horn and penner—Ancient writing outfit—Eastern writing implements—Survival of ink horn—Japanese writing box and pens—Their portable writing set—Early metal pens—Steel pens—Barrel pens—First patent for metallic pens—Improvements in steel pens with the object of increasing their ink-holding capacity — Reservoir nibs, various illustrations.

LECTURE II.—JANUARY 30.—*Stylographic Pens.*—Rudimentary forms—Early patents—Rigid points, needle points—Various writing or marking pens—Modern Stylographic pens, Nota Bene, Cygnet, and others—Gold pens, description of manufacture.

LECTURE III.—FEBRUARY 6.—*Fountain Pens.*—Early patents—Solid ink—Various reed arrangements — Self-filling reservoirs, flexible reservoirs, piston and plunger—Modern types of Fountain pens, Swan, Ideal, Conklin, Pelican, Unleakable, Wirt, Quill, Post, Autofiller, Fleet, &c.

JUVENILE LECTURES.

Wednesday afternoons, January 4 and 11, 1905, at Five o'clock, CARMICHAEL THOMAS, "The Production of an Illustrated Newspaper." (Two Lectures.)

LECTURE II.—JANUARY 11. — Compositors at work—Preparation of stereos—Manufacture of paper—The printing office—Folding and stitching machines—Colour printing—Importance of good titles—The editor's waste-paper basket—Curious sketches: the Russian censor—Foreign illustrated newspapers.

The lecture will be fully illustrated by lantern slides. An exhibition of drawings will be shown on the walls.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JAN. 9...Chemical Industry (London Section), Burlington-house, W., 8 p.m. Mr. Walter F. Reid, "Some Chemical Aspects of the St. Louis Exhibition."

Geographical, University of London, Burlington-gardens, W., 8½ p.m.

British Architects, 9, Conduit-street, W., 8 p.m.

Camera Club, Charing-cross-road, W.C., 8½ p.m.

Medical, 11, Chandos-street, W., 8½ p.m.

London Institution, Finsbury-circus, E.C., 4 p.m. Mr. H. Hill, "Studies in Spider Life."

TUESDAY, JAN. 10...Medical and Chirurgical, 20, Hanover-square, W., 8½ p.m.

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Sir William Henry White, "The Recent Visit to the United States and Canada."

Anthropological, 3, Hanover-square, W., 8½ p.m.

WEDNESDAY, JAN. 11...SOCIETY OF ARTS, John-street, Adelphi, W.C., 5 p.m. (Juvenile Lectures.) Mr. Carmichael Thomas, "The Production of an Illustrated Newspaper." (Lecture II.)

Biblical Archæology, 37, Great Russell-street, 4½ p.m. Annual Meeting.

Japan Society, 20, Hanover-square, W., 8½ p.m. "Japanese Under-Graduates at Cambridge University."

Royal Literary Fund, 7, Adelphi-terrace, W.C. 3 p.m.

Civil Engineers, 25, Great George-street, S.W. 3½ p.m. Sir William Henry White, "The recent visit to the United States and Canada." (Repetition of lecture.)

THURSDAY, JAN. 12...Antiquaries, Burlington-house, W., 8½ p.m.

Electrical Engineers, 25, Great George-street, S.W., 8 p.m. 1. Discussion on paper by Mr. W. P. Adams, "The Combination of Dust Destructors and Electricity Works Economically Considered." 2. Messrs. Wm. H. Booth and J. B. C. Kershaw, "Fuel Economy in Steam Power Plants."

Mathematical, 22, Albemarle-street, W., 5½ p.m.

Camera Club, Charing-cross-road, W.C., 8½ p.m.

FRIDAY, JAN. 13...Civil Engineers, 25, Great George-street, S.W., 8 p.m. (Students' Meeting.) Mr. James Swinburne, "Theory of Electricity and Magnetism."

Astronomical, Burlington-house, W., 8 p.m.

Philological, University College, W.C., 8 p.m.

Clinical, 20, Hanover-square, W., 8½ p.m.

Journal of the Society of Arts.

No. 2,721. VOL. LIII.

FRIDAY, JANUARY 13, 1905.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.

NOTICES.

NEXT WEEK.

WEDNESDAY, JANUARY 18, 8 p.m. (Ordinary Meeting.) CAPTAIN LIONEL JAMES, "Wireless Telegraphy and War Correspondence."

THURSDAY, JANUARY 19, 4.30 p.m. (Indian Section.) DOUGLAS W. FRESHFIELD, "The Gates of Tibet."

Further details of the Society's meetings will be found at the end of this number.

PROCEEDINGS OF THE SOCIETY.

JUVENILE LECTURES.

On Wednesday afternoon, January 11th, Mr. CARMICHAEL THOMAS delivered the second and last lecture of his course of Juvenile lectures on "The Production of an Illustrated Newspaper."

Mr. Thomas continued the history of the sketch which in his first lecture he had brought to the point of being photographed and made into a plate suitable for printing, through its further process of multiplication and preparation in the foundry and machine room. In some cases the drawing stood alone on a page of the periodical in which it was printed. More often it was accompanied by letterpress, the process of setting up which in type was described. The completed page of letterpress and illustrations was called a "forme." These "plates" or "formes" it was necessary to multiply, seeing that the whole issue of a newspaper could not practically be printed from a single set. First of all type and picture plate were locked together, and then were ready either to print from or to furnish duplicates. The preliminary step to obtaining the duplicate was to take an impression of the whole forme in plaster of paris, which was done by spreading the plaster over a sheet of stout paper, laying the paper very carefully down on the forme and subjecting it to such heavy hydraulic pressure that the plaster of paris sank into every line and scratch of the plate. The resulting impression was called the "mould," and it was next made dry and firm by baking. Thereafter metal "casts" could be taken from it, and for that purpose the mould was placed in an iron casting-box, into which molten metal was then poured and allowed to cool. The "cast" emerged therefrom identical in surface and appearance with the original plate. It had, however, to be "routed" by a revolving chisel, called the "router," which grooved out unnecessary portions of the metal. The back was smoothed by a second machine, and the cast was subjected to various processes in order to make it clean, neat, and workmanlike. Last of all it had to be hardened, so that its surface should give clear, strong impressions, and this was done by electrolysis. The plate was dipped into electric baths, by which its surface was coated successively with fine films of copper and nickel.

Having described all these processes and illustrated them by photographs, the lecturer interpolated a brief description of the processes by which grass and wood pulp were converted into paper suitable for printing. First the grass (of which the best variety was esparto grass) was "winnowed," cleaned, or separated. It then proceeded to the boilers and was made into pulp, which was bleached in the receptacle known as the "potcher," and was in succession strained and beaten till it resembled a custard of an exceptional kind. It might then be imagined as being fit for the paper-making machine, into which it went as pulp at one end and came out as paper at the other. In the first stage the pulp spread itself on a wide band of very fine wire netting, which retained the substance of the bulk but drained

off the water; in other stages grit was removed and the pulp was further strained. Air pumps sucked the moisture out of it, rollers hot or heavy or both pressed it and dried it and smoothed it, while at the end of the process, when the paper was about to come out in its solid condition, the final rollers glazed it preparatory to allowing to take its place in the great reels. These reels sometimes contained miles of paper. One that was made by Messrs. Spalding and Hodge, of which Mr. Thomas showed a photograph, weighed several tons, and the paper if unwound would have stretched out for nine miles and a half.

Returning to the progress of the plate, Mr. Thomas described the attachment to the great electrically-driven printing presses, and enumerated the last steps necessary to convert the impressed reels and lengths of paper into illustrated periodicals. When the paper had been printed the sheets were lifted on to trollies, which conveyed them to the warehouse, where they were folded, supplied with covers, and finally stitched by a most ingenious machine devised for the purpose. Last step of all before they were delivered to the newsagents, their edges were neatly cut and they were stacked in appropriate quantities.

But before leaving the description of the mechanical processes in the manufacture of the paper, an account was given of the methods of colour-printing to which were owing the production of the coloured plates that formed so attractive a feature of the Christmas supplements at this time of year. Formerly the reproduction of a coloured picture was a very complicated matter, and good results were usually obtained only by employing a large number of printings, sometimes as many as twenty. But a few years ago a new method of printing in colours, known as the three-colour process, was discovered and elaborated till it caused quite a revolution in the printing world. Every painting, it must be remembered, is composed of three primary colours, yellow, red, and blue. Suppose then we took three negatives, one of which would absorb all the yellow, another all the red, and another all the blue that existed in the picture, and turned these negatives into plates which could be used for printing. If we then printed on a piece of white paper the first plate in yellow ink, and on the top of it the second in red ink, and on the top of both the third in blue ink, the final result would be a composite reproduction which gave a remarkably good idea of the original picture. Having thus described the principle of three-colour printing, Mr. Thomas went on to exhibit some actual negatives and plates, and to show how by carefully superposing them the desired result could be reached. Very careful manipulation was required in the super-position, and the very best and purest light was necessary, in order that no mistakes should be made in the choice of the constituent hues. [The meeting-room was hung with some fine examples of the results obtained by this process of colour printing, and a picture was thrown on the screen showing the works which the *Graphic* has erected at Reading for the special purpose of making colour-prints of the highest class.]

Having set forth in their completeness the mechanical processes which secure the regular output of the weekly and daily illustrated paper, Mr. Thomas turned to the other side of their production, which was the work of the editorial rooms. He referred, first of all, to the demand which gave birth to the supply of newspapers—a demand which was nowadays usually felt most by those who, having been used to regard their newspapers as quite as regular a fact as their breakfasts, were temporarily cut off from them—and he quoted instances of the eagerness of the soldiers during the South African War to obtain newspapers, He also mentioned the curious fact that Sir Harry Johnston, while exploring Central Africa, had sometimes found a parcel of *Graphic* supplements of the greatest value in inducing African monarchs to come to terms. If, however, the demand for newspapers was great, some of the "materials" of supply were curious. The oddest apologies for drawings were sometimes sent in to editors, as some of his slides showed, and sometimes the oddest requests were made. One of the most curious sketches that had ever been sent to the *Graphic* was forwarded by a large employer of labour in the colony of Mahe on behalf of a released slave. These sketches were made by Billy King, and depicted his experiences from the time he was captured by the Arab raiders down to the time of his release by a British gunboat. They were published, as he now showed them, in facsimile, but not the least interesting part of them were their appended descriptions. These ran as follows:—

"The Arab often go out travelling in the mountain to get slaves—if one intempt to run they fire the gun with them.".

"When they had gather so many they carried all

down home. See they tight their hands; the little one as well and woman too."

"And at night when they sleeps, all the wood are tight up to the cross bar; one man always go up to tight the end."

"All the slaves are unlanding (unloading) and ready to be received on board."

"Now the rober are caught, they shout her once to start with, but they wouldn't stop; some time fire again and burn their sails till they get near."

"After having all out they put slave afar off, and light it with fire and burn it and ship go her way to Seychelles."

Mr. Thomas concluded his lecture by some references to the uses and misuses of illustrated journalism. One form of misuse was that inflicted on them by the Russian censor, who in one instance blotted out a *Graphic* picture, or photograph, in which the Czarewitch was shown hunting with the Nizam while in India. A good deal of speculation was hazarded on the reasons for the censor's action, and it was at last concluded that he objected to some words of the description printed underneath, which ran, "Unfortunately the Czarewitch did not get a shot." The censor must have thought it meant "Unfortunately the Czarewitch did not get shot." Another misuse of illustration was of a different kind, and it was that of which the Germans were guilty during the Boer War when they published as authentic drawings which purported to show British soldiers firing from behind women. An instance was given of the use of an illustrated paper in a very different and quite legitimate way. In March, 1895, during the Chino-Japanese War, the *Daily Graphic* published an illustration showing the attack on Wei-hai-wei by the Japanese. In the middle distance were the Japanese ships; in the foreground were three British ships, *Spartan*, *Edgar*, and *Centurion*. Away off to the right was a little ship, under which were the words "German flagship. Under sail only." This picture, coming into the hands of the German Emperor, furnished him with a striking object-lesson with which to support his scheme of German naval expansion. He had a copy of the picture placed on the seat of every member of the Reichstag on the day when the naval vote came on. On each copy was written, "Welch ein Hohn liegt darin," which translated meant, "What a mockery this is." The naval vote was passed.

The CHAIRMAN (Sir William Preece, K.C.B., F.R.S.), proposed a hearty vote of thanks to Mr. Carmichael Thomas for his interesting course of lectures, which was carried unanimously.

CANTOR LECTURES.

MUSICAL WIND INSTRUMENTS.

By D. J. BLAIKLEY.

Lecture IV.—Delivered December 19, 1904.

FLUTES.

It was noticed during the last lecture that many ancient Greek instruments, commonly referred to as flutes in our translations, were really reed instruments, and these, therefore, do not come into the category of flutes as we understand them. That tubes either of reed or of other material blown across the end were used in ancient days is, however, unquestionable; the tube of the common Pandean pipe and the ancient Egyptian Này now before you are instances.

The evidence of anything beyond this as concerns flutes blown directly from the lips is unreliable, but it is probable that the Greeks used a whistle flute, blown from the side by means of a mouth tube, and this may have been confused with the true flute as the name is now understood, or the Flûte Traversière.

The name flute in its broadest modern sense signifies an instrument in which a direct stream or blade of air, unassisted by a reed or any other contrivance, is the immediate cause of the vibration of the air-column.

Such a stream of air directed either down a tube, across an open end, or across a lateral hole, cut in some parts of its length, does not of necessity cause vibration. This result, vibration, depends upon the fluctuation of an induced current. In their detail the conditions upon which such vibrations depend are perhaps not yet thoroughly worked out, but some indications of the action of the air-reed or blast causing induced currents can be given.

The bird-call, or fowler's whistle, is a small hollow chamber of bone or ivory, with an inlet and outlet through which air can be blown from the mouth. The jet of air from the mouth in passing through the chamber carries with it a portion of the air in the cavity, thereby reducing the density of the remainder until, at a certain point, a re-action takes place. It is the rate of variation of density caused by the direct current which determines the pitch of the note.

Another example of an induced current was to be seen in the brazier's gas blow-pipe, the small lighting jet attached to the main gas tube travelling, when the air-jet only is turned on, in a direction contrary to that of the air current.

[This action was shown by direct experiment, but cannot well be described without the apparatus.]

These experiments, and others of similar character show that a stream or blade of air issuing steadily from an orifice such as may be formed by the lips, can, under certain conditions excite an alternating change of density in the air in its neighbourhood. It is this change of density which occasions the vibration causing the sensation of musical sound. The air-reed, in whatever way produced, may be regarded as an ultimate refinement of the reed made of solid elastic material which was considered in the last lecture.

The means adopted in the course of flute-making for the formation of this vibrating blade or lamina of air have been two. The first is by the passing of air from the mouth through a slit as in the common whistle, the blade thus formed passing across an orifice, and just grazing the lip on the opposite side. Flutes made on this scheme have now passed away, with the single exception of the flageolet, but as they illustrate a principle and have a distinct historical interest, I will show some on the screen. The lantern slide is taken from Kappey's "History of Military Music," and the instruments themselves are in the museum of the Royal Conservatoire of Music at Brussels. A whole group of recorders is here shown, the large bass instruments being furnished with a crook or bent tube to convey the wind to the whistle part of the instrument. In all of them the typical six finger-holes are seen, and in the larger instruments some extension of the compass downwards is provided for by key-work.

One of the instruments of this family was the pipe used with the tabor. This instrument had two finger-holes and one thumb-hole only, but as the first octave was not used, the three holes sufficed to give the *d*, *e*, and *f*, required to complete the scale between *c* and *g*, the second and third proper tones, and also the other notes lying between the higher harmonics.

With this slight account of the recorders or whistle-blown type of flute, we must pass on to those which have more interest at the present day, and are "flutes" strictly speaking, as we now understand the term. All these depend for speech upon the action of a stream of air issuing directly from the lips without the intervention of a whistle mouthpiece of any kind. This flute is probably not more than 500 years old, and in its simplest form is a cylindrical tube with a mouth-hole bored near one end, and with a plug or cork inserted a little beyond the mouth-hole. Such a tube corresponds in length to a half wave-length of its lowest note, and is capable, by over-blowing, of giving the octave, twelfth, &c., or notes in the harmonic series.

The oldest known instrument of this kind is the Schweizerpfeiff or Zwergpfeiff (Swiss-pipe or Dwarf-pipe), a flute with the normal six finger-holes, and without keys for the semitones.

These cylindrical flutes were poor in tone, and incorrect in tuning in the over-blown octaves. It is manifest that the mouth-hole is not an exact equivalent of the open end, and this divergence causes departures from the normal law of vibration in cylindrical tubes.

The first attempt at correction was by giving a conical form to the greater part of the flute, leaving the head-joint cylindrical. This correction in conjunction with the gradual addition of key-work resulted in the disappearance of the English flute or recorder, in favour of the German or transverse flute, which held the field for about two centuries. Its chief faults were due to the supposed necessity of having holes covered by the fingers instead of by artificial pads wherever practicable.

About the middle of the last century Theobald Boehm, putting into a practical shape ideas that appear to have been at least held by others, produced a flute in which every note speaking through a side-hole was fully vented by holes below it, by which means great equality of tone was gained. He subsequently discarded the plan of covering the holes directly by the fingers, and substituted key-work. He further returned to the original cylindrical form of the flute, and obtained correct intonation in the octaves by giving a curved conoidal form to the interior of the head joint. These alterations entailed a modification of the established fingering, but Boehm's principle has made great way, and now practially holds the field.

As one example of conditions bearing upon a point admittedly somewhat obscure, we may consider the influence of that part of the flute lying between the mouth-hole and the cork-stopper. It is certain that the tone quality is much influenced by the proportions of this space, and in all probability a subsidiary vibration of a high note of constant or nearly constant pitch is here set up. This note, being blended as a partial with the general

tone of the instrument, gives a distinct colouring, to which is due the sense of unity of quality, and also of individuality, running through the whole compass of the instrument.

We may take an illustration from another organ of sense than the ear—the eye. We may see a landscape with its distinctive greens, browns, purples, and other colours under ordinary light, and yet the general effect may be greatly modified either by a grey sky, or by the rays of a setting sun. So with sound. We may have groups or a succession of very distinct wave-forms, but these are capable of modification by the introduction of another wave-form which shall be common to all.

This view which I put forward tentatively does not apply only to the flute, for analogous conditions are to be found in brass and other wind instruments.

The attempt to summarise the chief points in the developments of wind instruments leads to the following conclusions as regards the different classes.

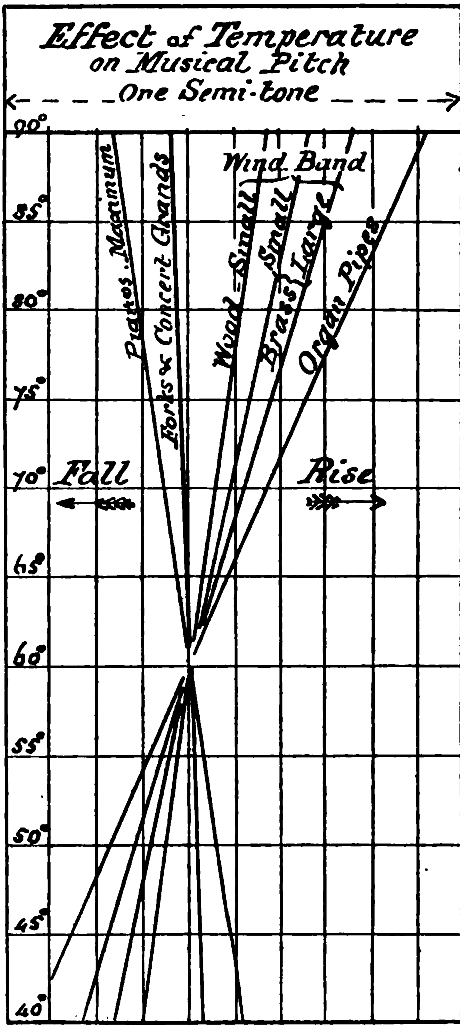
Brass Instruments.—The direct action of the lips as applied to the most simple horns has been maintained throughout all improvements and modifications.

Reed Instruments. — Reeds enclosed in chambers, and therefore not under the direct control of the lips, have passed away so far as artistic music is concerned.

Flutes.—A similar result is to be observed. The air-reed issuing from a mechanically formed slit, as in the recorders and other beaked flutes, has passed away.

We find, then, that all attempts to improve upon the wonderfully sensitive action of the lips by mechanical means have disappeared, but the work which lies fairly within the province of design and mechanism, that is to say, the determination of the proportions of a tube to give particular intervals and tone-quality, and the instantaneous regulation of its length in accordance with the requirements of the musical scale, so that it shall be suited in every way for response to the impulse of the lips, has been very marked during the last century.

Temperature is one natural condition which has an effect, in greater or less degree, upon all instruments; and although the full consideration of its influence would take more time than is at our disposal, a brief reference to it will not be out of place. Change of temperature affects the pitch of all instruments, and if all groups were influenced in the same direction and to the same extent, the result, in practical music, would be small, for all instruments would rise or fall together. The effect of heat upon metals being to expand them, a tuning fork is rather longer when warm than when cold, and is consequently flatter in pitch. If the expansion of the metal were the only effect of heat upon a brass



instrument, the same result would follow; but another influence is at work, producing five or six times the effect in the contrary direction. This influence is the greater velocity of sound in warm than in cold air. The change of pitch corresponding to this increased velocity is equal to a rise of a quarter of a tone between 47° and 73° Fah., a very ordinary range of temperature. This change is exhibited to its full extent in organ flue-pipes: the reed pipes

are affected in varying degree. All the wind instruments we have been considering in these lectures are when in use more or less warmed by the breath, and this prevents the external changes of temperature having the full effect they otherwise would have. In the diagram a range of temperature is shown from 40° to 90° Fah., and a range of pitch of one semi-tone divided into tenths. At 60° the various instruments are assumed to agree in pitch, and their different rates of departure from unison is shown by the positions of the various thick slant lines.

The lecture was illustrated by lantern slides and experiments, and also by the following musical illustrations :—

Flute solos, Chant Pastorale, Mazurka, *Andersen*, Mr. H. Warner Hollis. Horn solo, Romanza, *Karl Maty*, Mr. T. Busby. Concertstück, *Rietz*, flute, oboe, clarinet, horn, bassoon, and pianoforte, Messrs. Hollis, Fonteyne, Gomez, James, and Busby. Pianoforte, Mr. R. H. Walthew.

BUILDING BYE-LAWS AND RURAL DEPOPULATION.

There is general agreement that the question of rural housing is of great and pressing importance. It is so because it is intimately associated with the problem of rural depopulation. The higher wages offered in towns, the greater freedom, the more varied life, the fuller opportunities, all these considerations appeal to the young and ardent, and conduce to the depopulation of the country side. But none has greater weight with the young villager than the absence of house accommodation. The agricultural labourer marries young. At an early age he can command the highest wages open to his class. The prudential considerations which weigh with others and retard marriage do not affect him. But whilst the choice of a wife may be easy oftener than not he can find no house suitable to his wants. The cottages in the village are all occupied and no new ones are built. Even the old ones as they crumble away are not replaced. Single, the village youth can either live at home or in lodgings, married he must migrate for there is no cottage vacant. And this knowledge quickens the exodus to towns which is such a deplorable feature of our times. Nor is it likely that the emptying of the country-side will be checked until the rural cottage problem is solved.

It seems strange at first sight that there should be any such problem to be solved. Statesman, landowner, farmer, all are anxious to keep the labourer on the land. Why then refuse to house him properly? The answer is that under present conditions cottages cannot be built at a cost that will give a reasonable, or, in many cases, any return upon the capital invested. An agricultural labourer cannot afford to pay more than 3s. a week for a cottage; indeed, assuming constant employment, and an average of 15s. a week, this rent charge may be thought excessive, and many agricultural labourers are less favourably placed. Three shillings a week means roughly £8 a year. Now, under present conditions, a cottage in the country with a garden costs, exclusive of the land on which it is built, at least £250. Deduct from the £8 £1 for rates, and another £1 for insurance and repairs, and without reckoning anything for depreciation and management, the net return per annum is only £6 upon an outlay of £250, or less than 2 per cent. If cottages are to be put up by landowners generally in sufficient numbers to meet rural requirements, they must not cost more than £150 each. Hence the present search for the means by which such houses can be provided.

This question of construction of labourers cottages has been frequently discussed in the pages of the *Journal*, and as far back as 1863 two prizes of £25 each were placed in the hands of the Council of the Society of Arts, by Mr. J. Bailey Denton, to which was added the Society's medal, to be offered for the most approved designs for cottages with three bedrooms in each, to be built singly or in pairs, at a cost not exceeding £100 each. The limit of cost may be particularly noted. In those days it was not a question whether cottages could be built for £150 apiece, or thereabouts. That was taken for granted. Thus in the discussion following upon a paper read by Mr. John Taylor, jun., a well-known architect in his day, at the meeting of the Society on December 10, 1862, Mr. Bailey Denton said, "The average cost at the present moment of cottages with three rooms, with water supply and the necessary fencing, was £260 a pair. He was speaking not merely of his own experience but advisedly from the experience of those who were largely engaged in building. £260 a pair for cottages was too large a cost, and it was an object worthy of the Society, and of the country at large, to endeavour to reduce the expenses from £260 to about £200 a pair." And Mr. Ebenezer Clark, who followed, said that "he held a contract which was now in course of execution for building cottages as low as £225 per pair. . . . The front room was 12 feet by 10 feet, the back room being about the same size, with a washhouse at the back, and containing a capital oven, copper, sink, and dresser, and a good water-closet. There were two good rooms upstairs and a porch in front." True there were only two bedrooms, and nowadays three are thought necessary, but the cost is noticeable. How is it that cottages cannot now be put up for less than £250? The explanation is not to be found in advanced cost of wages and material, but largely in vexatious building bye-laws.

Up to seventy years ago parochial affairs in rural England were managed in each parish by its own vestry. And this at least may be said for the vestries, that in a purely agricultural parish the interests looked

to were purely agricultural ones. Then came the new Poor Law with transference of powers from Vestries to Boards of Guardians, from villagers meeting and debating in the village to men who met in the town. But there was no great change in practice until after 1894. Until that year the rural district consisted of the area of the Poor Law Union, exclusive of any urban district that might be within it, and the Guardians of the Poor were the real sanitary authority. Since 1894 this has been changed. By the Local Government Act of that year the Guardians ceased to be the rural sanitary authority. The Union was preserved as the rural sanitary district with this qualification—that if it extended into more than one county it was divided so that no rural district should extend into more than one county. Rural district councillors are elected for each parish in the rural district, and the rural district council have ceased to be the same body as the guardians, and are now wholly distinct. By a clause in the Public Health Act of 1875 it was declared that the Poor Law districts might, if they so chose, declare themselves through their guardians to be "urban districts," and so acquire powers similar to those exercised in towns. It sometimes happens that in a district otherwise rural there are some centres of population, hardly large enough to be constituted urban districts, which, nevertheless, require the same control as an urban district, and it was considered desirable to take the power to confer upon a rural district council in respect of such a populous area the right to make bye-laws relating to buildings, &c. But it was never intended that such regulations should be made applicable to the whole of the purely agricultural areas included within the rural districts. Unfortunately, this has happened. In 1896, the Local Government Board confirmed orders investing rural councils with urban powers in 163 cases, many of which were applications for bye-laws relating to streets and buildings. In 1897, the number was 117, and so it has gone on until in a large number of rural districts it has become impossible to build cottages except of brick and stone, and subject to other unnecessary restrictions all making for expense. "It is almost incredible, but it is a fact," writes Mr. Read, the honorary secretary and treasurer of that excellent body, the Building Bye-Laws Reform Association, "that a house in London not more than 30 ft. high, and certainly not more than 125,000 cubic feet, being 8 ft. from the nearest road, and 30 ft. from the nearest building, and from the land of any adjoining owner, can be built of almost any material, but in most of the rural districts which have adopted urban bye-laws such a house must be of brick and stone! And almost any rural council that chooses to apply can get these urban powers. For example, in the *West Sussex Gazette*, of October 13 last, may be found the notice of an Order of the Local Government Board investing the rural district of Horsham with all the powers of an Urban District Council under the Public Health Acts. Now what sort of a district is that of Horsham? It has an area of 76,613 acres, a population of 17,381, and 3,840 inhabited houses. Thus the Horsham Rural District, which is to come under urban liabilities, has approximately one house on every twenty acres, and one person on every 4½ acres! It may be asked why the Local Government consents to the use by any such Rural District Council of the powers exercisable by an Urban District Council. The explanation is that the Local Government Board, in the absence of evidence to the contrary, assumes it to be the wish of the ratepayers concerned, but this assumption is a fiction. To take the Horsham case. Probably not one person in a hundred of the 17,000 who are affected by the notice has ever seen it, and of the people who have seen it not one in ten understands that it is the precursor of a code of bye-laws which will be an injury alike to the individual and the community.

It will never be possible to erect cottages in the country which it will pay landowners to build and labourers to live in until every man has the right to put upon his land any building he desires provided only that he does not endanger public health or public safety. In the towns the jerry builder can crowd upon the ground houses in whose construction the bricks used are so bad as to be scarcely fit for the foundation of a garden path, while the other materials he uses and the sanitary work are no better in quality. In the country a landowner desirous of erecting a cottage in his own park, using the best materials, a mile away from his next neighbour, is liable to be called upon to pull it down if it is not in conformity with the bye-laws of the rural authority, however absurd those bye-laws, originally framed for an urban district, so applied, may be. The experiences of Mr. Justice Grantham are within the recollection of all. Not long ago Earl Roberts had a similar difficulty with the rural authority of the district in which his property is situated, though, on the Local Government Board's recommendation, the Council did not proceed to extremities. And so with many others. Mr. Wilfrid Blunt's experience is perhaps as remarkable as any. He gives it in the *Nineteenth Century and Afterwards* for October. Wanting a small dwelling in a hurry Mr. Blunt applied to Humphries, who advised iron, and put him up exactly what he wanted. "It was," says Mr. Blunt, "as snug and sanitary a house as any poor man could wish to inhabit," and it cost £130. The occupants were pleased with it, the neighbours admired it, and even the District Council informed Mr. Blunt that "there appears to be no objection to your proposals except as to thatched roof." The thatch was got rid of and Mr. Blunt thought himself safe. But he did not know his Council. Fresh objections were taken and he sought advice as to what he should do. He was advised to take no notice and trust to the county magistrates inflicting a nominal fine if the District Council took action. This they did, with the result that Mr. Blunt was fined £5, with a continuing penalty of 2s. per

day whilst the cottage stood. The Council could not say there was anything the matter with it. On the contrary, they admitted that "it was a better and healthier building than the Council's bye-laws allowed to a single storied cottage not of brick or stone." That was the unpardonable fault in the eyes of the Council—it was not of brick or stone.

Why insist upon brick and stone? Why exclude wood; or wood and lath and plaster; or wood and iron; or wood and some patent substance, such as "Uralite," or "wire wove" material; or concrete in blocks and slabs? The Local Government Board has, it is said, determined that timber cottages shall not be built, because they are "dangerous structures." Are they more dangerous than thousands of jerry-built houses put up every year in London? And apart from that, can it be reasonably contended that timber cottages are necessarily "dangerous structures?" "Thousands of old wooden cottages," writes the author of "Modern Cottage Architecture," "have served their purposes for centuries all over England, not to mention the excellent eighteenth century Colonial work still standing in America and elsewhere built entirely in wood. . . . If we turn to the New World to-day with all its goahead enterprise, we find that no one in America for ordinary purposes has ever thought of building houses outside the townships of the United States in any other material than timber. . . In Norway and Sweden, of course timber of necessity is universally used for house construction, risky things being done in actual practice there which we should scarcely imitate here. Nevertheless neither of these countries is disproportionately conspicuous for deaths from fire in wooden houses." Of course the timber must be "well seasoned," sound, and practically free from sap, the carpentry must be workmanlike, and the whole structure should stand on a damp proof course over a dwarf wall of brick, concrete, or stone. Concrete has many advantages where a number of cottages are wanted. Lately, six cottages were built in the Clare and Ross method, of concrete and timber, at Colnbrook, with an upper floor, and having two bedrooms, and a smaller one, for £150 each house. Unfortunately the Board of Agriculture follows the Local Government Board in its dislike of wood. Under the auspices of the Board of Agriculture landowners can borrow money for cottage building on very favourable terms, but only if the dwellings are to be of "brick, stone, or other incombustible material." On these the landowner may raise money at 3¼ per cent., spread over 40 years; but if it is desired to build concrete blocks, or wood, or expanded metal and plaster cottages, the Board offers no help. Its contention is that the law gives it an enormous power in allowing it to over-ride mortgages, and that a full security must be obtained for "the remainder man." The argument would be more convincing if the Board did not countenance first charges for twenty years on farm buildings of wood. Nor is the further argument that cottages of other than "brick or stone," are uninsurable to the amount of the rent charge more conclusive. The Norwich Union, established in a region where wood and plaster cottages are well known, will effect such insurances.

The position taken up by the Local Government Board and the Board of Agriculture in favour of "brick or stone," encourages District Councils to insist upon having them, and these authorities are further persuaded to vexatious interference with the building operations of landowners by the knowledge that only in very rare cases will they resist them. It is not necessary here to inquire into the considerations by which District Councils are swayed in declaring themselves "Urban Districts," and applying to the country side building regulations never intended to be put in force outside towns. It is sufficient to say that in very many districts the District Councils stand in the way of cottage building, since their requirements make it impossible for landowners to put up cottages that can be let at a rent that will give anything like a reasonable return upon the capital invested. The Building Bye-laws Reform Association has drafted a Bill, which is now before Mr. Long, to exempt, under certain conditions of isolation, cottages and other buildings from being subject to any building bye-laws except those relating to sanitation, and some such short amending Act would seem to be desirable. But even if the oppressive action of District Councils is checked, and the landowner is given a free hand within the limits indicated, it would be rash to assume that the cottage problem will be solved. As Mr. C. Cochrane puts it, "In the Home Counties, the North of England, the near proximity to towns, and where other industries have been established locally, the £150 cottage will be a great help when there is a real desire to build. But what is to be done to house the fast decreasing population in districts where wages are 13s. a week, or even less, and the old cottages are falling down in ruin and neglect?" Here surely the local authorities might adopt Part III. of the Housing of the Working Classes Act, 1890, and build where necessary a few cottages which shall not lay a burden on the rates, and which can be occupied by the better-off of the village people whose vacated cottages might be used to accommodate those unable to pay high rates. Unfortunately, the pressure of public opinion is often wanting where the need is greatest, and selfish interests are allowed to over-ride the public good.

The proprietors of the *County Gentleman*, at the instance of Mr. J. St. Loe Strachey, are utilising its pages to endeavour to bring about a state of things under which it will not only be possible to erect a £150 cottage, but easy to discover plenty of firms ready and able to erect such a cottage. Under the same auspices there will be next summer a practical exhibition in London that will seek to show by physical examples what can be done in the way of cheap cottages. It is an excellent idea that should be supported by all who are concerned to stay the depopulation of the country-side.

ELECTRICITY FROM WATER-POWER.*

It should be gratifying to our national pride to know that probably the very earliest example of the production of electricity by means of water power on a practical scale, and its transmission to a distance, was the installation put up for the purpose of lighting at Cragside, Northumberland, by the late Lord Armstrong, in the year 1882. This plant, which was still in daily use in 1884, when the author saw it in operation, consisted of a Siemens continuous-current dynamo, which was driven by means of a belt off an 8 horse-power water-turbine operating with a fall of 30 ft., the electricity, which was delivered at 90 volts pressure, being carried by bare overhead wires attached to porcelain insulators on poles to the house, about a mile distant. It is an interesting fact that when the installation was first put to work it was designed to operate with only a single wire, connection being made to the hydraulic power pipes at the one end and to the ordinary household water-pipes at the other, the earth being expected to form a sufficient return in the manner employed in telegraphy. This plan, which was adopted on the advice of the late Sir William Siemens, was found to be quite ineffective, as, owing to the low voltage employed and the exceedingly rocky nature of the ground, no useful amount of electricity could be transmitted, until the earth return was done away with, and a second metallic conductor substituted.

Though this 22-year-old English example of electricity developed by water-power and transmitted to a distance was, as already mentioned, probably the first such installation in existence in the world, the great development of such installations has, up to recently, taken place almost exclusively abroad. No doubt, up and down this country a very considerable number of small electric plants operated by water-power have been put for private house lighting and such like purposes, and there are even towns—such as, for instance, Salisbury and Keswick—where water-power has for long been employed to assist steam-power for electrical production for public and private lighting, the water-power being in these instances found of great value for the purpose more especially of maintaining the supply during the periods of minimum load. A few hundred horse-power will, however, probably cover the whole of the plants of this character at present running in Great Britain, which is an altogether insignificant amount compared with the much larger corresponding figures for the continents of Europe, America, and other countries.

To obtain accurate statistics as to the amount of water horse-power at present employed for electrical production throughout the whole world is a very difficult matter, as in many countries no figures are available, while in others such as are obtainable are not up-to-date.

* Paper read by A. A. Campbell Swinton before the British Association at Cambridge.

The following Table, giving an aggregate horse-power of nearly one and a half millions, comprises all the hydraulic electricity works of which the author has been able to obtain particulars. He has, however, no doubt that there must be many others in existence to which he has not been able to find any reference; while again, in the case of a number of the installations which have been included, the horse-power now employed is greater than that in use at the time that the statistics were made out.

WATER-POWER ELECTRICITY INSTALLATIONS.

	Horse-power.
United States of America	527,467
Canada	228,225
Mexico	18,470
Venezuela	1,200
Brazil	800
Japan	3,450
Switzerland	133,302
France	161,343
Germany	81,077
Austria	16,000
Sweden	71,000
Russia	10,000
Italy	210,000
India	7,050
South Africa	2,100
Great Britain	11,906
Total horse-power	1,483,390

It, therefore, seems reasonable to suppose that the total amount of water-power actually used for electrical production throughout the world at the present time must exceed 2,000,000 horse-power, which is about double the total steam power at present devoted in Great Britain and Ireland to the same purpose.

It is interesting to calculate what would be the amount of coal required to produce this large amount of horse-power were it generated by steam-engines in the ordinary way. In other words, what is the saving of coal that the adoption of this amount of hydraulic power entails. Many of the hydraulic plants, particularly those which are used for chemical processes, operate at full power continuously night and day, but others work for shorter hours. Assuming, however, that the whole 2,000,000 horse-power is in use for 12 hours per diem—in other words, is employed on the average with what engineers call a 50 per cent. load factor—and assuming, as is reasonable, that were the energy produced by means of coal, at least 3 lb. of this fuel would be required on the average per horse-power hour, we get 5·86 tons of coal per horse-power year, or 11,720,000 tons of coal saved annually on account of the two million water horse-power utilised. Though this may appear a large figure, it amounts to less than 2 per cent. of the total output of coal in the world, which, on the average of the last five years, was 632,000,000 tons per annum. Assuming, however, an average cost of coal of 10s. per ton, this 11,720,000 tons represents

£5.860,000 yearly, an amount which it would take over £100,000,000 of capital earning 5 per cent. per annum to provide.

Apart from mere magnitude, many of the more recent examples of hydro-electric engineering abroad, especially in America, are interesting by reason of the enormous distances over which the electric energy is being economically transmitted, and the very high electric pressures that in numerous cases are being successfully employed.

The longest distance over which transmission has so far been commercially effected is probably the 232 miles of line belonging to the California Gas and Electric Corporation, which stretches from the de Sabla power-house, *viâ* Cordelia, to the town of Sausalito, which is situated on the opposite side of the Golden Gate Straits from the city of San Francisco. What this transmission means will be realised when it is stated that the distance covered is about equal to that which separates Cambridge from Newcastle-on-Tyne. The same Californian company also owns the Colegate and Oakland transmission line, which runs 142 miles from the Colegate power-house, where 14,000 horse-power is developed from a head of water of 702 ft.

Another very long line is that which reaches from the electric power-house *viâ* Stockton and Mission San José to San Francisco, a distance of 147 miles, over which 10,000 horse-power is being delivered regularly. This line belongs to the Standard Electric Company, who have 217 miles of power line, with a capacity of 27,000 horse-power in operation. The voltages employed, as it is to be expected having regard to the distances covered, are very high, ranging from 55,000 to 67,000 volts, 60,000 volts being apparently the standard figure for many recent installations, of which the following are some examples:—

Plants recently Installed by the Stanley Electric Manufacturing Company, Pittsfield, Massachusetts.

Name.	Horse-power capacity.	Voltage.	Transmission distance.	Head of water.
			Miles	Feet.
Quanajuato Power and Electric Company, Mexico	8,000	60,000	101	300
Washington Water Power Company, Spokane	12,000	60,000	110	68
Kern River Power Company, Los Angeles, California......	16,000	67,500	110	—
Pierce Company	26,000	55,000	40	—
Mexican Light and Power Company, Mexico	—	60,000	110	1,500
Winnipeg General Power Company......................	10,000	60,000	60	40
Canadian Niagara Power Company	—	60,000	93	—
Electric Development Company of Ontario	—	60,000	93	—

For these particulars the author is indebted to Mr. C. C. Chesney, chief engineer of the Stanley Electric Manufacturing Company, who have recently installed these and numerous other similar plants.

Mention should also be made of the 50,000 horse-power and the 125,000 horse-power plants for the Canadian Niagara Power Company, and the Electrical Power Company of Ontario, contracted for by the Canadian General Electric Company, both of which will employ pressures ranging up to 60,000 volts; while to pass to another quarter of the globe, the Cauvery Falls electric power scheme in India has now been at work for over two years, and transmits 5,000 horse-power to the Mysore gold mines, a distance of 92 miles, using a pressure of 35,000 volts.

(*To be continued.*)

MINING AND METALLURGICAL INDUSTRIES OF SPAIN IN 1903.*

This report, by Mr. Ronald Macleay, of His Majesty's Embassy at Madrid, affords a very interesting insight into Spanish activity, both in its national aspect, in the tables giving the total output, and in minuter detail in the returns and reports from the various provinces. At the outset, a distinction is clearly drawn between the mineralogical and the metallurgical sides. The value of the minerals produced at the mouth of the mines in 1903 amounted to £5,398,741, an increase of £301,572 over 1902, while the value of metals produced at various works aggregated £5,923,100, an increase of £196,097 over the value in 1902. The mines absorb the bulk of the population engaged in these industries; 94,351 people were engaged in productive mines in 1903, an increase of 6,843 individuals in the mining population as compared with 1902. In 1903, 22,488 workpeople were employed in the works, as against 22,299 in 1902, being an increase of 189 persons during the year. The demand for mechanical power is increasing at a greater rate than is the absorption of the population in this employment. In 1903, the number of hydraulic engines at the works (probably water-wheels or turbines) was 83, of 3,340 horse-power, whilst in the preceding year there were only 53 of such engines, of a total of 2,525 horse-power; the steam engines employed in the works have increased by 21, of 3,480 horse-power. At the mines, 265 more steam engines were employed in 1903 than in the preceding year, representing an increase of 8,412 horse-power.

During the period under review, in the mining industry there has been an increase in the production of copper, iron, argentiferous iron ore, sulphur, mercury, lignite, lead, and common salt, while on the other hand there has been a decline in the production of tin, coal, manganese, and argentiferous lead. Of the output of the different factories,

* Diplomatic and Consular Reports, No. 623 Miscellaneous Series. Eyre and Spottiswoode, London.

hydraulic cement increased by 43,438 tons, cast-iron by 43,217 tons, sheet iron by 18,832 tons, steel by 6,451 tons; the output of nails, wire, and manufactured iron increased, but the production of wrought iron decreased by 10,902 tons. There was also a lessened production of certain classes of copper, zinc, and of quicksilver.

Zinc is worked at 126 mines, in which 2,971 persons are employed, the value of the output at the mouth of the mines being £157,044. Copper, worked at 501 miles, provided employment for 12,141 persons, the output of 2,799,789 tons being valued at £1,569,369. Iron ore (hæmatite), which is used so largely in England was obtained at 662 mines, in which 30,073 persons were engaged, the output of 8,304,150 being valued at £1,301,407. Coal, mined at 605 places, provided employment for 20,717 persons, of whom 1,203 were females (263 of these were under 18 years of age). Only 2,587,652 tons of coal were raised, the value being £709,210. Lead mines are of two classes, those producing ordinary lead, and those producing argentiferous lead. In the former 486 mines yielded 108,660 tons, valued at £363,584, and employed 9,177 persons. In the latter case 227 mines yielded 179,858 tons, valued at £896,806, and employed 10,941 persons.

The relative amount of male and female labour is given in the following Table;—

Males employed underground:—	
From 16 to 18 years	5,174
Over 18 years	36,799
Males employed above ground:—	
From 10 to 16 years	3,318
From 16 to 18 years	6,011
Over 18 years	40,270
Total number of males	91,572
Females employed above ground:—	
From 10 to 16 years	160
From 16 to 18 years	705
Over 18 years	1,914
Total number of females	2,797

To every 100 males, 3 females are employed, a proportion which, considering the nature of the work, is rather surprising for a European country.

The returns concerned with the metallurgical industries are models of concise and valuable information. The number of works are given in which different minerals are treated, the horse-power of the machinery in use, the amount of ore treated, and the quantity and value of the finished product. Only one factory was concerned with the working of zinc; employing 471 hands, and receiving 12,740 tons of ore (about one-twelfth of the total amount mined); 2,636 tons of zinc ingots and 2,649 tons of zinc sheets, valued respectively at £55,356 and £67,446, were produced. Nine factories were concerned with the winning of copper. In these, 1,660,092 tons of ore (about 60 per cent. of the output) were treated. The yield was 13,138 tons of copper cascara (*i.e.* of the shell or husk of copper obtained from copper in solution flowing over ferric oxide), valued at £551,806. There were also produced 7,704 tons of copper blister worth £416,021, and 5,906 tons of copper sulphate worth £88,596.

As regards the iron industries, the following Table shows most concisely what took place in the nineteen works in operation in 1903, where 11,220 males and 316 females were employed, and the indicated horse-power of the steam engines in use aggregated 33,386:—

Class of Product.	Output in tons.	Value of output in £.
Cast Iron	302,657	737,661
Wrought Iron	1,661	13,461
Sheet Iron	48,943	422,666
Manufactured Iron	7,571	129,464
Steel	24,177	204,308
Wire	2,038	20,787
French Nails	1,395	20,297

These works consumed 772,785 tons of iron ore, or about one-twelfth of the volume of the ore mined in that year.

As regards fuel, 756,758 tons of coal were converted either into patent fuel or coke, the respective productions being valued at £202,588 and £394,281. Only 352 females are employed in the metallurgical industries, of whom 41 are under 16 years of age, while 22,136 male workers are employed.

Of the provincial reports, mention need only be made of that from Vizcaya. The "Nuestra Señora del Carmen" iron works produced 111,562 tons of pig iron. Of this total, 89,258 tons were treated by the Bessemer process, and yielded 83,227 tons of steel; 4,150 tons treated by the Siemens process yielded 1,724 tons of steel; and 3,200 tons were used in puddling, and yielded 2,872 tons. The works known as "Los Altos Hornos de Vizcaya" obtained 76,393 tons of pig iron from 157,140 tons of ore. Of this pig-iron, 25,350 tons were converted by the Thomas process into 21,569 tons of steel, and 12,716 tons yielded 3,043 tons of basic steel. The "San Francisco" Iron Works converted 78,716 tons of ore into 38,543 tons of pig iron: these works produced 2,530 tons of steel by the Siemens process, but from pig iron that was in stock from the preceding year. All these figures serve to show in a striking manner the trend of an industry to the source of one of its raw materials. How far, if at all, imported fuel from Great Britain serves to feed the Spanish furnaces is not stated.

One misprint, apparently the omission of an asterisk on page 9 may be mentioned. The yield of mercury stated is obviously an impossible one.

In its entirety, this report is both valuable and interesting. If it and its fellows received more attention from the daily Press, we should hear far less of the alleged superiority and surpassing commercial value of the American Consular Service.

LETCHWORTH.

On Wednesday next, the annual meeting of the Garden City Association will be held at Essex-hall, and the publication of the sixth annual report is an opportune time for glancing at the progress of a very interesting experiment. The primary object of the Association, namely, to secure healthful and adequate housing in a city in which the inhabitants shall become, in a collective capacity, the owners of the sites, subject to the proper recognition of public as well as individual interests, must command the sympathy of all. Nor is it less desirable to encourage the tendency of manufacturers to remove their works from congested centres to the country. The difficulties in the way of such an enterprise are obvious and many, but the Association seems to be making fair headway.

The estate upon which the experiment is being tried is about 3,800 acres in extent, situated between Hitchin and Baldock, in Hertfordshire. It has been purchased at about £40 per acre, inclusive of building and timber, and the town that is to grow out of it will be known as Letchworth, the population of the town area (1,200 acres), being limited to 20,000. A company, First Garden City Limited, has been formed with a capital of £300,000, of which £100,000 has been called up to develop the estate, but the profits of shareholders are limited to a cumulative dividend of five per cent. per annum, all profits beyond this being applied for the benefit of the town and its inhabitants. Considerable progress has already been made with the development of the town. Water works have been put up; several miles of mains have been laid; a large drainage scheme has been completed; an up-to-date gas plant will be ready for use in July; and various new roads have been constructed. Plots for a large number of houses have been let, and sites have been definitely selected by manufacturers, including G. Ewart and Sons, Geyser manufacturers, London; Idris and Co., mineral water manufacturers; Mr. A. W. Collier, stationery manufacturer; The City Press, printers; Hitchin, Vickers and Field, ashphalt manufacturers, London, The Garden City Laundry Company, London. Printers, lithographers, cabinetmakers, are likely to be particularly well represented at Letchworth. It is claimed that a manufacturer occupying an acre of land and a factory costing £10,000 in Garden City, will save £2,000 in rent and rates alone as compared with London, and as each of his *employés* will also obtain a saving in rent as well as a large garden the all-round advantage is much greater. Rates should remain low because the Garden City Company will do a large amount of the work usually done by local authorities, such as the carrying out of scavenging works, the interest on the capital unemployed being met by the revenue from building sites. The train service is excellent, there being 52 trains to and from Hitchin daily, the fastest taking 39 minutes from Hitchin to King's-cross. There will be sidings to each factory when needed, ample space for factories to be economically planned and extended when required, plenty of light and air, cheap and pure water, low insurance, cheap gas for power, cheap building materials.

For the workers there will be good housing, large gardens, and ample recreation. The rent for workmen's houses will be 5s. 9d. and 8s. a week. The house let at the weekly rental of 5s. 9d. has downstairs a living room, kitchen, scullery, and three rooms upstairs, each cottage being supplied with a bath. The 8s. houses have an extra room. Each cottage has attached to it a tenth part of an acre of garden ground. A well-known building society has agreed to advance up to £20,000 on the estate so that workmen will be encouraged to purchase their own dwellings, and many cottages are now being put up at a cost of not more than £115 to £130. In every case the society's architect must approve of the design. It is not intended that there shall be more than seven houses to the acre. The factories like the cottages will have to be built in accordance with the requirements of the Association. The freehold will not be parted with in any case.

There will be an agricultural belt round the town, and small culture will be encouraged. The promoters of the scheme properly attach great importance to the success of *petite culture*, but those who know the district are disposed to question the suitability of the soil. They say that it is almost impracticable land and only suitable for corn growing. It is a little surprising that the chairman of the company, when giving evidence before the Inter-Departmental Committee on Physical Deterioration, admitted that he thought it "very likely" that the land was as described, but that he had not inquired into the matter. If the land is not suitable for small culture a leading object of the Association will be defeated. And many other serious difficulties in the way of the general and permanent success of the venture will occur to all who give the matter consideration. For example, suppose the population of the city expands to the limit, and one of the manufacturers wants to increase his establishment to an extent that might mean the employment of another 200 or 300; or the cottages are allowed to go to rack and ruin as they do in the country; or that workmen, brought by a manufacturer, come from the slums of London; or that the middleman is allowed to creep in between the company and the manufacturer; or that the occupants of cottages disregard the restrictions as to overcrowding? These are some of the difficulties that the organisers of Letchworth will have to grapple with as time passes and the city becomes fully inhabited, but they ought not to be insuperable. Anyway, the experiment is one which deserves, and will command the heartiest good wishes of all who recognise how vital it is to the welfare of the country to lessen the overcrowding in our towns and the depopulation of the rural districts. The nature of their business must prevent many trades migrating to the countryside, but others are finding it

to their advantage to do so, for London is fast becoming an impossible centre for works of large dimensions, and the greater the decentralisation of trade the better the chance of enabling the workers to live in healthy surroundings such as they are promised at Letchworth.

EXPERIMENTAL SCIENCE IN THE SECONDARY SCHOOLS OF IRELAND.*

The education given in the secondary schools of Ireland is controlled and guided, in large measure, by a body of Commissioners known as the Intermediate Board. This Board was constituted by Act of Parliament in 1878, and administers a fund of about £90,000 a year. For many years this fund was distributed on the results of examination alone; and the programme of the Board was not favourable to the study of experimental science in the schools. But in the year 1900 the Board was empowered, under a new Act, to supplement examination by inspection, and, in the distribution of grants, take account of the results of inspection as well as the results of examination.

This change led to an important reform, in which the Board has been greatly aided by the co-operation of the Department of Agriculture and Technical Instruction. To this Department was transferred, in 1901, the administration of the Parliamentary vote for science and art in Ireland, which had been previously administered from South Kensington. As the Intermediate Board and the Department were dealing with practically the same schools, it was agreed to adopt a common programme in science subjects, and to carry out a common system of examination and inspection.

The programme adopted under this arrangement, which includes two years of a preliminary course and two years more of advanced teaching in various special subjects, is fully set out in the paper. It involved, in effect, an entirely new departure in the teaching of experimental science in Ireland; substituting, to a large extent, practical work in the laboratory for the study of books, and testing the efficiency of schools by actual inspection of the work done, as well as by written papers.

One of the chief difficulties encountered in the introduction of this new system was to provide a supply of competent teachers. This task was taken up by the Department, as the training of teachers does not fall within the functions of the Intermediate Board. The plan adopted was twofold. First, summer classes for teachers were held at various centres; and teachers who attend these classes, and afterwards satisfy the examiners, obtain provisional certificates to teach the course in which they have been so trained. This is only a temporary expedients intended to meet the urgent need of the moment.

But as the permanent element in their scheme the Department propose to grant the "Irish Teacher's Science Certificate" to all students who pass through a three years' course, prescribed for the purpose, in the Royal College of Science, Dublin. They will also recognise as qualified teachers students who have followed a similar course in any university or technical college, and who have obtained the corresponding degree or diploma.

The next difficulty was the want of laboratories and laboratory equipment. This difficulty has been met by the cordial and very remarkable co-operation of the schools and the local authorities with the efforts made by the Department and the Intermediate Education Board. The Department designed plans to suit the circumstances of each particular school and prescribed the necessary apparatus to be provided. Then loans were advanced by the Intermediate Board, and grants were made by the Department to help the schools to meet the cost of building and equipment. The county and borough councils also lent their aid in many cases, by allocating to the same purpose a portion of the funds placed at their disposal for technical education. The result has been that 214 schools are now provided with all that is needed for the two years' instruction of the preliminary course; and many of these are further provided with the equipment prescribed for one or more years of the special courses.

The new system now embraces all the secondary schools of the country, about 250 in number, with a school population of about 20,000 pupils. Of these 20,000 pupils, somewhat more than 9,000 were under instruction in the preliminary course during the school year 1903-4, and about 1,500 in one or more of the special subjects. This represents a very satisfactory progress, in what is practically a new line of study, within the short period of four years.

It is encouraging to hear that the subject of experimental science, taught on the new lines, is popular both with teachers and pupils. I am informed that a large number of pupils have developed quite a remarkable taste for laboratory work, and that many who had been regarded as dull and inert in other studies, have shown themselves alert and bright in this new field of nature knowledge that has been opened to them.

* Abstract of paper read by Rt. Rev. Gerald Molloy, D.D., before Section L of the British Association at Cambridge.

COTTON PICKING MACHINE.

Mr. George A. Lowry, of Boston, Mass., a member of the Society of Arts, has invented a machine which has been exhibited in action at Shreveport, Louisiana. The following account of the demonstration is taken from the *Shreveport Times* of December 18th last :—

The inventor of the Lowry auto-cotton picker claims that his machine, operated by five boys, will pick twenty-five times more cotton than the average negro

hand picker of the south, and the demonstration of his machine was given in the presence of many prominent cotton men of Shreveport and planters from the surrounding country on the Foster plantation, three miles from the station, on the 17th December.

Mr. Lowry and Colonel Jerome Hill, of Memphis, who has been in business in that city for thirty years or more, have been in the city since the opening of the national cotton convention, and intended to give an exhibition of the cotton picker on the 14th inst., but on account of the non-arrival of the machine the exhibition was postponed. The trip to the Foster plantation was made on a special train over the Vicksburg, Shreveport and Pacific railroad.

The machine picked one whole and two half rows of cotton clean within a very short space of time. All of the witnesses were of the opinion that Mr. Lowry had the correct theory; that the machine he has now, which is to some extent in a crude state, would, when perfected, do everything its inventor claimed for it. The machine did what it was advertised to do, and that was really to pick cotton.

In picking with the Lowry picker human brains direct the machinery to the open bolls, the machine withdraws the cotton from the boll, carries it to the bag, and carries the bag. The operator is seated, and his only duty is to see that the machine, or that portion of it which is termed the "arm," is brought into contact with the open bolls. The machinery does all of the other things, and does them well. Four negro boys, two of whom never before saw the machine, operated the "arms," and each picked at the rate of 126 bolls per minute. It is estimated that the machine will pick at least 3,000 pounds of cotton in one day. This estimate is made on the accepted ratio that it requires the seed cotton out of from 70 to 100 bolls to weigh a pound. Gasoline furnishes the motive power for propelling the machine, and the cost of a day's consumption is a very small item.

The cotton bolls used in the demonstration were as full as they could possibly be, and the plant was dry and brittle, but notwithstanding this the cotton was picked almost without any trash.

A special feature of the Lowry cotton picker is its simplicity, which will make it a hard matter for it to get out of gear, and any man who has ever operated a common gin can operate the picker.

After the exhibition, which lasted about an hour, the following resolution was unanimously adopted and signed by all present:

"Resolved, That, having witnessed on the Foster plantation, near Shreveport, La., the Lowry cotton picker at work, we are pleased to certify it as a success and an invention that solves the most serious problem that confronts the cotton-grower to-day, and we thank and congratulate Mr. G. A. Lowry for having conceived and put into operation a machine that enables one man to pick five times as much cotton as he could with his unaided hands. We commend it to the cotton producers of the south."

BOOT AND SHOE INDUSTRY OF THE UNITED STATES.

The last official census of the United States shows that there were in operation in this country during the census year 1900 1,600 boot and shoe factories, representing a capital of 101,795,233 dols., giving employment to over 150,000 people, and having an annual product valued at over 260,000,000 dols.

During the past ten years the number of factories has decreased by 23·2 per cent., the amount of capital has increased by 6·8 per cent., aud the value of the product has increased by 18·3 per cent. In 1890 there were in operation 2,082 factories with a product of 220,000,000 dols., and during the ten years a large number of the small establishments have either closed entirely or were absorbed in larger companies, the tendency of the time being toward consolidation of the business into large establishments.

Another feature of the development of the industry in the past ten years is the increased use of machinery and the improvements in methods. In spite of this, however, the figures prepared by the census show that it is costing more to manufacture shoes at the present time than it did ten years ago. There was an increase of 42·8 per cent. in the cost of materials during the decade while the value of the finished product shows an increase of 18·3 per cent.

Since the invention of the rolling machine—the first practical mechanical substitute for hand labour—there has been constant progress in the perfection of shoe machinery. The shoe factory of to-day provides a perfect system of continuous manufacture, involving, in some instances, more than 100 operations. The continued improvement of the various machines, together with the keen competition in the business, has made necessary the adoption, as soon as perfected, of the latest devices. This will be seen in the increase for 1900 over the previous year in the value of machinery, tools and implements required for a product valued at 100 dols. The total increase for this item is 3,083,941 dols., or 22·2 per cent. for the industry.

While the manufacture of boots and shoes in other sections of the United States has made marked progress, New England still maintains the lead in the industry, the output for that section in 1900 representing 59·5 per cent. of the total for the United States. The output of the factories of Massachusetts for 1900 was 117,115,243 dols., or 44·9 per cent. of the total for the entire country, compared with 52·7 per cent. in 1890, a decrease of 7·8 per cent., although showing a small increase over the value of the products of the State for the decade.

Massachusetts ranks first in the value of production as well as in all other points in connection with the manufacture of boots and shoes. The total capital invested in this industry in that State was 37,500,000 dols., and the total number of wage earners was nearly 60,000, and the value of the product 117,115,000 dols.

New York ranks second in the amount of capital, average number of wage earners, and value of products. From 1890 to 1900 the gain in capital was 32,348 dols. in a total of 11,983,239 dols., while the output increased from 23,661,204 dols. to 25,585,631 dols.

The third rank in point of production belongs to the State of New Hampshire. This State shows an output valued at 23,405,558 dols., with 12,007 wage-earners, who received 4,971,954 dols. In 1890 it required 7,912 workers to produce 11,986,003 dols., the State then ranking fourth in all items except that of capital.

Ohio ranks fourth in the value of its product with a total of 17,920,000 dols. The capital invested in Ohio was over 7,500,000 and the number of *employés* 12,7000. The value of the product of boots and shoes in the United States, divided according to the principal lines, was as follows :—

Products.	Number of Establishments.	Quantity (pairs).	Value.
Men's boots and shoes	561	68,042,839	$108,705,938
Boys' and youths' boots and shoes	389	21,080,479	20 799,297
Women's boots and shoes	589	65,372,953	82,504,303
Misses' and children's boots and shoes	552	42,043,202	30,319,611
Men's and boys' and youths' slippers	136	4,456,965	2 812,213
Women's, misses' and children's slippers	279	12,655,876	10,146,393
All other kinds	127	5,583,405	2 491,511
All other products	161	—	2,175,738
Amount received for custom or contract work	148	—	1,073,576
Total	—	219,235,419	261,028,580

The lists of the cities in the United States having an output of boots and shoes valued at more than 5,000,000 dols. is as follows :—

Cities.	Rank.	1900. Value of Product.
Brockton, Mass.	1	$19,844,397
Lynn, Mass.	2	16,830,733
Haverhill, Mass.	3	15,231,440
Cincinnati, Ohio	4	8,788,424
St. Louis, Mo.	5	8,286,156
Rochester, N.Y.	6	6,933,111
Philadelphia, Pa.	7	5,931,045
Brooklyn, N.Y.	8	5,733,432
Chicago, Ill.	9	5,723,126

A noteworthy feature of the history of the development of the boot and shoe industry in this country is the fact that until well along in the last century there was little or no attempt to establish the industry outside of eastern Massachusetts, at the present time in New York City and in other parts of New York State, especially in Rochester, the industry has assumed large proportions and has reached a high state of perfection. In Newark, New Jersey, where the business was early established, there are now made many of the finest shoes for men.

Philadelphia has long ranked the manufacture of shoes as among the most prominent of its many manufacturing industries. In Cincinnati and in St. Louis during recent years shoes have been produced in great quantity and of excellent style and finish. Chicago has also taken up the industry with characteristic energy and has assumed a prominent place at the present time. All through the West, including the Pacific Coast, new factories are being established which are thoroughly well equipped and promise to be successful.—*Commercial America.*

A PLAN FOR A UNIFORM SCIENTIFIC RECORD OF THE LANGUAGES OF SAVAGES.*

During the last thirty years, the careful record of "savage" languages has been frequently undertaken, and a serious difficulty has arisen owing to the accepted European system of grammar, which is based on a system originally evolved for the explanation of highly inflected languages only, whereas in many, if not in most, "savage" languages inflection is absent or present only in a rudimentary form. The European system has therefore been found to be unsuited for that purpose. During attempts to provide a suitable system a theory of universal grammar was evolved.

The root idea is that, as speech is a convention devised by the human brain for intercommunication between human beings, there must be fundamental natural laws by which it is governed, however various the phenomena of those laws may be.

The theory starts with a consideration of the sentence, *i.e*, the expression of a complete meaning, as the unit of all speech, and then seeks to discover the natural laws of speech by a consideration of the internal and external development of the sentence.

In explaining internal development the sentence is ultimately divided into words, considered as components of its natural main divisions, in the light of their respective functions. This leads logically to a clear definition of grammatical terms.

From the consideration of the functions of words, the theory passes to that of the methods by which they are made to fulfil their functions. It shows how words can be divided into classes according to function and explains their transfer from class to class. This leads to an explanation of connected words and shows how the forms of words grow out of their functions. The growth of the forms is next considered, involving an explanation of roots, stems, and radical and

* Abstract of paper read by Sir Richard Temple, Bart., C.I.E., before Section H of the British Association meeting at Cambridge.

functional affixes. This explanation shows that the affixes determine the forms of words. This is followed by a consideration of the methods by which the affixes affect the forms.

The sentence, *i.e.*, the unit of speech, is then considered as being itself a component of something greater, *i.e.*, of a language. This consideration of its external development leads to the explanation of syntactical and formative languages, the two great divisions into which all languages naturally fall—*i.e.*, those which depend on the position of the words, and those which depend on the forms of the words, in a sentence to express complete meaning.

Syntactical languages are then shown to divide themselves into analytical, or those which depend for comprehension mainly on the position of the words, and into tonic, or those which combine tone with position for the same purpose. So also formative languages are shown to divide themselves into agglutinative and synthetic, according as the affixes are attached without or with alteration. Formative languages are further divided into premutative, intromutative, or postmutative, according to the position of the affixes.

The theory further explains that, owing to a fundamental law of nature, no language can have ever been left to develop itself alone, and how this leads to the phenomena of connected languages, and thus to groups and families of languages. It also explains how—again according to a law of nature—no language has ever developed in one direction only or without subjection to outside influences, leading to the natural explanation of the genius, or peculiar constitution, that each language possesses.

It is believed that every language must conform to some part or other of the theory, and it can be shown that children and untutored adults in learning a language act on the instinctive assumption of the existence of such a theory. Assuming the theory to exist and to be correctly stated, it is of great practical importance as leading to the quick, accurate, and thorough, because natural, acquirement of a new language.

In brief, the theory is based on the one phenomenon which must of necessity be constant in every variety of speech, viz., the expression of a complete meaning, or, technically, the sentence. Words are then described as components of the sentence, first, as to the functions performed by them, and next as to the means whereby they fulfil their functions. Lastly, languages are considered according to their methods of composing sentences and words.

Phonology and orthography—*i.e.*, pronuuciation, spelling, and alphabets—are not considered, as these belong to other branches of the development of the human mind.

The theory has been already applied—and, it is claimed successfully--to sixteen languages, including English, Latin, and Hungarian, selected for the purpose as being illustrations of every type and every kind of development.

THE MINING INDUSTRY OF BRITISH INDIA.

There has of late been a distinctly satisfactory progress in the mining industry of India, the most marked development being in the production of coal, gold, petroleum, and manganese ore, while progress has also been made in the minerals of smaller value. Activity in prospecting has also shown a decided increase, for the number of prospecting licenses issued in 1903 was 90, as compared with 83 in 1902. Owing to the dullness of the coal trade in 1903, the output of coal in that year, though progressive, showed an arrest of the rapid expansion which has characterised the industry for several years. With a total production of 7,438,386 tons, India now takes the lead as a coal producer in the British Empire outside Great Britain. The Raniganj Jherria and Giridih coal fields still retain their lead as coal producers, and the proximity of the first two to Calcutta enables them to meet the requirements of the export trade, which, however, is necessarily confined to Indian Ocean ports, and consequently somewhat limited. India is yearly approaching a state of being able to supply all her own wants in fuel, as the import of foreign coal has been shrinking rapidly, and amounted in 1903-4 to 180,040 tons imported as merchandise, and 26,789 tons as Government stores, this being one-fourth of the quantity imported nine years previously. All but a quarter of the private imports was, on the authority of the Director-General of Statistics at Calcutta, English coal, mostly landed in Bombay, the remainder coming from Australia and Japan. The Indian railways take, naturally, a large share of the coal produced in the country, the consumption having risen steadily from 1,059,158 tons in 1894 to 2,203,889 tons in 1903. In the case of gold, besides the steady rise in output from Kolar, where the gold mining industry has gradually expanded since 1894, and during 1903 reached a total of 600,000 ounces, work has commenced in the Nizam's dominions, and during the ten months, February to December, 1903, 3,414 ounces of gold were raised. In Burma there has been a decline in the output, from 2,179 ounces in 1902 to 1,095 ounces in 1903, on account of the exhaustion of the reefs in the Katha district. A certain amount of washing for gold is carried on in the rivers of the Punjab, Chota Nagpur, and Burma, and dredging operations with promising results have commenced in the upper reaches of the Irawadi river. The development of the petroleum resources of Burma and Assam has exceeded the rate of growth in the coal trade. In 1902 the production amounted to nearly 57 million gallons, and this represented a substantial increase on previous years. In 1903 the output rose to nearly 88 million gallons, of which over 85 million gallons were produced in Burma. The production for Assam has risen from about 1¾ million gallons in 1902 to 2½ millions in 1903. In addition to a low-grade burning oil and solid paraffin, petrol is

now being manufactured. The most remarkable development has taken place in the quarrying of manganese ore. This industry, commenced little more than ten years ago by quarrying in the deposits in the Vizianagram State, and from an output of 3,130 tons in 1893, the production rose rapidly to 87,126 tons in 1899, when the richer deposits in the Central Provinces were also attacked, and are now yielding a larger quantity of ore than the Vizianagram mines. In 1903, the total output for India reached a record of 171,800 tons, which places India amonst the first two of the countries producing high-grade manganese ore. The ore raised in the Central Provinces is of a very high grade, ranging from 51 to 54 per cent. of the metal, and is used principally in steel manufacture in Great Britain, Germany, and the United States. The production of salt in India, which averages about a million tons annnally, fluctuates with the seasons. The total in 1903 was only 894,840 tons, owing to the much smaller production in Bombay and Madras. The largest proportion of salt produced in India is sea salt, made on the coast in Sind, Bombay, Madras, Burma, and Aden. The quantity so made on the Indian coasts in 1903 represented more than two-thirds of the whole production. Saltpetre, which is largely produced for export, was in former years of much greater importance than now, the diminished demand for gunpowder and the preservation of food, with the competition of the nitrates, having operated to prevent an expansion of the exports. It is most largely produced in Bihar, whence the article is sent to Calcutta for export after refinement. The native iudustry in smelting iron, which has existed in most parts of India from very ancient times, has undergone a gradual decline in the face of cheaper iron and steel imported from Europe. Except in Barakar, where the conditions for the manufacture of pig-iron are favourable on account of the proximity of ore supplies and good coking coal, no successful attempt has been made to manufacture iron on a large scale in India. In the case of mica, India still retains the lead among the producing countries. The centres of production are in the Nellore district in the South, and a belt of pegmatiles near the borders of the Hazaribagh, Gaya, and Monghyr districts in Bengal. Little or no work has been done in the other areas where the mineral is known to occur in plates of marketable size and quality. The mining for graphite still continues in the Travancore State, where the mineral occurs under geological conditions similar to those of the richer deposits being worked in Ceylon. The output for 1903 amounted to 3,394 tons, as against 4,595 tons in 1902. Amongst other minerals of value, the magnesite deposits of the so-called "Chalk Hills," near Salem, in the Madras Presidency, have attracted attention on account of the great purity of the mineral, which is found to be suitable for the manufacture of fire bricks for linings and hearths of steel furnaces. Complete statistics of the output of jadestone in Burma are wanting. The substance which passes as jadestone is mainly the mineral jadite which occurs with serpentine in an altered igneous rock in the Myitkyina district of Upper Burma. Tin mining is carried on on a small scale in Southern Burma and the Karenni. The quarrying of slate is an important industry along parts of the outer Himalayas, near Rewari in the Punjab, and in the Kharakpur hills of Monghyr district. In the Kangra valley the material obtained is a highly fissile quartz schist, not a true slate, and in consequence of the facility with which it can be split into thin large sheets and resists the action of the weather, it is for roofing purposes superior to ordinary clay slate.

"BASTARD" LOGWOOD.

A correspondent of *Nature* quotes from the Jamaica *Bulletin* of the Department of Agriculture for November, 1904, an article on this subject by B.C. Gruenberg and William Gies, contributed originally to the *Bulletin* of the Torrey Botanical Club.

During the past few years the growers of logwood in Jamaica have been greatly disturbed by an apparent increase on their properties of an unmerchant able variety of the plant known as "bastard" logwood; the exportation of this wood along with real logwood has served to condemn all the logwood from the districts which have shipped it.

"Bastard" logwood differs from the genuine varieties, from the dyer's standpoint, in yielding little or no hæmatoxylin, but instead a yellowish-green pigment which is of no value, aud which, when mixed with the commercial extract, reduces the characteristic tinctorial properties. Chips of the "bastard" logwood present a yellow, pale pink, white, or even chocolate-coloured surface, instead of the dark red or deep purple bronzed-tinted colour of the best logwood. There appears great uncertainty, even when the trees are cut down, as to whether a tree is really a "bastard" tree or not. What is known as a "bastard" tree is frequently dark enough when first cut to lead one to believe that it is a good red-wood tree, but instead of darkening with age it remains the same colour, or becomes lighter rather than darker. "Bastard" wood is not the result of disease or of any lack of vigour; the trees producing it are perfectly healthy and normal.

It is not the result of soil or climatic conditions, since bastard and normal trees are found growing side by side under absolutely identical conditions.

It is not the result of immaturity; aged trees may produce bastard wood.

These facts point to heredity as the probable cause of the trouble: that is, certain trees produce "bastard" wood because they grow from seed of a "bastard" tree; in other words, "bastard" logwood is a variety of *Haematoxylin Campechianum* that normally produces little or no hæmatoxylin. The chemical differences existing among all these logwoods are quantitatively very slight, and there are no strik-

ing structural differences among all the varieties of logwood.

There can be no doubt that "bastard" logwood is a distinct variety or subspecies of *Haematoxylin Campechianum*, notwithstanding the slight morphological difference that distinguishes it from the "red" logwood and blue logwood.

The Jamaica *Bulletin* has done good service to the colony in bringing the fact prominently before the planters that the admixture of useless wood which has been the source of unnecessary loss to them may be avoided.

PAPER-MAKING MATERIALS IN CHINA.

Rice straw is the commonest paper-making material in the province of Ssuch'uan, which derives its name of "Four Streams" from the four rivers, Chialing, F'o, Min, and Yaling, flowing through it from north to south into its great trade highway the Yangtsze, and is the largest and probably the richest province of the empire of China. This straw paper, of which there are several qualities, is used for wrapping goods, in the manufacture of fire crackers, for making paper money, so much in demand at all funeral ceremonies, for pipe spills, and for a variety of other purposes. The straw is made up into bundles and steeped with water in a deep concrete pit for a month, when it is taken out and well washed. The water in which it has been steeped is removed, and the straw is spread in layers in the pit, each layer being thoroughly sprinkled with slaked lime, and water containing the catty (1⅓ English pounds) of soda to each 100 catties (133⅓ lbs.) of lime. There it remains for 20 days. At the end of this period the straw has been reduced to a pulp, which has sunk to the bottom of the pit. The surface water and as much as possible of the lime are removed, and the pulp is taken out, placed in a steamer and steamed with 1 per cent. weight of soda, when it is ready to be made into paper. A quantity of the cold pulp is placed in a trough of cold clean water, to which is added some mucilage extracted from the *Hibiscus Abelmoschus*, a wild plant and cultivated in Ssuch'uan, and a fine oblong bamboo frame, the size of the desired sheet of paper, held at the two ends by a workman, is drawn down endways and diagonally into the liquid contents of the trough. The contents are well stirred before the frame is used. It is then gently raised to the surface, and the film what has gathered on the top, drops off as a sheet of moist paper when the frame is turned over. This paper is kiln dried and made up into bundles for market. The following, according to Consul General Hosie, is the method employed in making the paper money or paper cash referred to above. The trunk of a tree six feet or more in circumference, and about six feet high, sat up in the verandah of a shop is the usual signboard of a paper cash factory. Standing on a scaffolding which brings his elbows well above the top of the trunk a man takes a bundle of this coarse paper several inches thick and about six inches square, and with a wooden mallet exactly the same as that used in finer stone work in England, hammers an iron chisel consisting of a central pointed iron spike with two sharpened concave scoops on either side through the paper till the spikes and scoops reach the trunk. This he repeats in parallel lines all over the bundle till each sheet is covered with cash shaped perforations consisting of a round centre and two half moon shape slits held together by the paper between the scooped openings. The sheets are always used whole, and no attempt is even made to subdivide them into the cash which they represent, but the paper is so cheap that even a Chinese does not think it worth his while to study economy in this matter. Sheets of paper cash are scattered on the roadway in front of the coffin when being borne to the grave, and burned at the grave itself after the burial has taken place. This paper is also moulded with tin into the shape of sycee, and it also goes largely to make up the flimsy sedan chairs which are burned at the grave as offerings to the departed. Two kinds of bamboo are used in Ssuch'uan for the manufacture of paper, the "Tzu Chu" and the "Chin Chu." They must be tender stems usually of the same year's growth, and in no case must they be more than two years old. They are cut into lengths of eight feet to suit the size of the concrete pit, where they are steeped in bundles with cold water, and heavily weighted with stones. After three months they are removed, opened up and well washed. They are then stacked in layers, each layer being well sprinkled with lime and water containing about two pounds and a-half of soda to every 133 pounds of lime. After two months they are well retted. The lime is then washed out, and they are steamed for fifteen days with three pounds of soda to every 130 pounds of the fibrous mass which on removal from the steamer is thoroughly rinsed with cold water. It is then placed in a concrete pit and reduced to fine pulp with wooden rakes. After this it is ready for conversion into paper. A quantity of the pulp is put into the trough, with cold water and mucilage from the *Hibiscus* referred to above, as in the case of the coarse straw paper. The whole is thoroughly stirred and the frame passed into the trough and raised with the film of paper in the usual way. This paper is much finer, whiter, thinner, and more expensive than straw paper. There are of course various qualities used for different purposes—from papering windows to fine writing and note paper. Much of this paper is coloured on one side as well as dyed, and very often note or card paper is glossed with white wax to give it a smooth polished surface. Paper is manufactured all over the province of Ssuch'uan, but the great centres for bamboo paper are Mien Chu Hsien, Chiung, Chou, and Chia-chiang Hsien, while Lu Chon on the Yangtsze, west of Chungking, produces very large quantities of straw paper. The *Broussonetia papyrifera*, or paper mulberry, attains

to the dimensions of only a bushy shrub, but no attempt is made in the provinces to manufacture paper from its inner fibrous bark. The tough "bark paper" or "Pi Chih" made from this plant, and so extensively used in China, comes from the province of Kueichon. There is one prominent use to which this light, pliable, tough paper is put in Ssuch'uan. In all fur-lined and wadded garments the chief desiderata are lightness, warmth, and the protection of the material lined from being frayed by the skin or wadding. As is well known a fur is usually made up of a number of skins sewed together and these seams present an uneven surface which would in time wear the silk or satin material lined. This wearing is prevented by inserting a layer of this paper, which presents an even surface to, and preserves the material. Cotton and silk wadded garments are treated in the same way when there is a risk of unevenness proving injurious. Lightness, warmth, and durability are the result. The *Fatsia papyrifera* is the source of the fine thin pith paper so well, but erroneously known in China, as "rice paper." The plant which has no connection whatever with rice, is cleverly shaved from the round pith of the plant by means of a sharp heavy knife. The pith is largely exported. In Canton this paper is largely used for painting, but in Ssuch'uan it is mostly converted into artificial flowers. It grows wild throughout the province.

IMPROVEMENT OF COTTON GROWING IN INDIA.

One result of the formation of the British Cotton Growing Association has been to call attention to the great deterioration which has taken place in the quality of the cotton grown in India during the last twenty years. The Association's investigations have caused the Government of India to consider what steps it could take to improve the grade of the cotton exported from India. The Department of Revenue and Agriculture has accordingly issued to the various provincial governments a long letter on the subject. The Government recognises that the question is largely a commercial one, and that cotton growing will expand only if cotton is made more profitable to cultivators than other crops, and that the longer or finer staples (which are so highly prized in Lancashire) will be grown only if they prove more profitable than short staples, for which there is already a very large foreign demand. Mnch has already been done by the Inspector-General of Agriculture in pushing on systematically a botanical survey of Indian cotton, while the steps now being undertaken should prove very effective in improving the staple.

One of the main causes of the deterioration of Indian cotton has been due to carelessness in the selection of the seed. This has been occasioned by the practice, which has become general in recent years, of sending all the cotton grown to ginning mills, and getting back for sowing purposes any seed which might be ready for sale. The Government memorandum, therefore, suggests that in order to collect a sufficient quantity of good seed, agents of the Agricultural Department should be appointed in each cotton-growing district as seed collectors, to go round at the cotton picking season and select the best fields of the local well-known varieties. The produce of the fields selected would be purchased, the seed hand-ginned, collected, and carefully stored, the lint of the crop being sold to the best advantage. Only the seed from healthy plants would be taken, and this would be sold or distributed to cultivators on the approach of the next sowing season. The aid of the owners of the cotton ginning mills is to be enlisted, in order that they may gin separately any good lot of cotton, separating its seed for sale only to those parts of the country proved to be suitable for that particular variety of cotton. In order to further the adoption of this proposal, the Government of India is willing, if any local Government accepts the scheme and is prepared to spend an equal sum from provincial resources, to contribute a grant of 5,000 rupees.

The Indian Government has also agreed to contribute in equal shares with the British Cotton Growing Association, a sum of £6,000 towards the resources of a syndicate formed to promote the growing of long stapled cottons. Besides starting practical cultivation on a large scale, the syndicate will undertake the experimental cultivation and selection and improvement of suitable varieties of seed. When the varieties likely to give the best results have been ascertained, they will be cultivated on a number of small demonstration farms, for the purpose of illustrating to the ryots the advantages they promise and the best methods for their cultivation. The main object of the syndicate is, of course, to increase the production of long-stapled cottons suitable for the Lancashire mills.

TECHNICAL EDUCATION IN THE FAR EAST.

Professor Perry and his fellow labourers, who, some twenty years or so ago, by their services at Tokio University (and elsewhere) in Japan, founded Japanese technical education, will be interested to learn that a number of young Nepalese and Hindu students are now studying in Japan. Comparatively few young Indians come to England to study technical subjects. Occasionally a young Mohammedan has won honours at Cooper's Hill, while some years ago the Gaekwar of Baroda sent over several young Hindus to study technical subjects. Of course large numbers of Indians always come to London to read for the Bar. It seems that the high caste Hindu or Mohammedan of old family regards the law as more dignified than manufacturing or railway work. The only entrance to the Indian Bar being *viâ* the Inns of

Court, no counter attractions lead them to study law elsewhere. In regard to technical study Japan now seems to be offering the special attractions of a cheap training, together with less disagreeable climatic changes. The entrance standard at Tokio University is a high one. Quite apart from the Japanese language, which the regulations state should be read in primers before leaving India, and which can be learnt in about eight months, German must be learnt. It seems that all Japanese students on entering the University are able to read any German books on a a technical subject, and that many of the professors freely mix German and English technical terms in their lectures, while others make exclusive use of German terms.

Technical education in India has been specially patronised by Lord Curzon, and the various colleges of Sibpur, Rurki, and Madras train large numbers of engineers for the Government service. It is surprising though that fifteen Indian students are at Tokio (eight of whom come from Nepal), while others are at Kobe and Osaka. At the present time it is doubtful whether there are five Hindus in England studying engineering subjects. Whether the young Hindu will find it wise to learn two strange tongues in addition to the English learnt at school, is another matter. Experience alone will show whether the climatic compensations will counterbalance the scholastic loss, if such there be.

CANARY ISLANDS TOBACCO.

The Spanish Government, in order to help the farmers who grow tobacco, has compelled the tobacco régie in Spain to take from the Canary Islands every year for the next four years 220,000 pounds. At present the crop amounts to 132,000 pounds, but more will be planted in the future. The Government has also sent an experienced horticulturist to see to the cultivation and consider what improvements can be made, so that Spain at some future day may be independent of Cuba in regard to certain qualities of tobacco that are bought there. The tobacco will only be bought from the growers and none will be accepted from dealers or speculators. All samples will be transmitted to Madrid subject to the approval of the board of governors of the tobacco régie before being bought, and the price paid for the tobacco will be the same as the ruling price paid in Habana for Remedios tobaccos at the time these crops get to the market. In the island of La Palma, where nearly all of the tobacco of the Canary Islands is grown, fully 20 per cent. of the male population have been at one time or other in Cuba, and have worked in tobacco plantations. The American Consul at Teneriffe, who has had considerable experience in the tobacco trade, gives it as his opinion that the quality of the tobacco grown in La Palma is far better than the Remedios of Cuba; all that is necessary, is to give more attention and care to the planting and cultivation, as well as to the curing. He is also of opinion that in years to come it will compare favourably with the famous Vuelta Abajo crops.

CORRESPONDENCE.

RUBBER CULTIVATION IN SIAM.

In the number of the *Journal* for November 11 (p. 886) I find an article with the heading written above which contains more erroneous and extraordinary statements concerning the cultivation of rubber plants than is usual in ordinary popular papers, and was hardly to be expected to be met with in the *Journal* of the Society of Arts. Consul-General Nash, of Bangkok, fears, it seems, "the so-called disease which has developed in the Para rubber plantations of the Malay Peninsula. About this pest nothing very definite can be learned, except that it attacks the leaves and is very destructive." There is *no* such disease known in the Malay Peninsula; there is *no* disease of any part of the Para tree of any great importance or which could possibly be called very destructive. The author is probably referring to the canker of the stem and branches which has been seen in one or two cases in the Malay Peninsula. It is not very important, and is very easily checked. He next proceeds to state that *Ficus elastica* is found in large quantities in the Siamese jungle and throughout India and Indo-China generally. It is certainly absent altogether from the greater part of India, but occurs in Assam. It may occur in Siam and Indo-China, but it is certainly not abundant. The amount of rubber taken from six-year-old trees, *i.e.*, four pounds, is much exaggerated.

As to the wonderful *Urceola*, with its extraordinary growth of six or seven feet in two or three weeks, one would certainly be glad to know more about it, as its growth as given, is just four times as rapid as the most rapid-growing plant of any kind known to botanists, viz., four inches a day.

Equally extraordinary is the statement that the rubber is obtained by cutting the creeper into sections two or three feet long and collecting the juice. "The bark is also used, and being pounded and boiled, gives about 10 per cent. of inferior rubber." The rubber latex, in all species of *Urceola*, *Willinghheia*, &c., is *confined exclusively to the bark.* There is nothing to be got out of the stem other than the bark except water. The writer has probably confused the native methods of dealing with these plants, common all over Eastern tropical forests, by hacking at the creeper so as to draw off the latex from the bark, with a process employed in French Indo-China of treating the bark collected by the natives in the forests and brought to the settlements. The fact is that the rubber-vines *Urceola*, *Willughbeia*, and *Landolphia* are slow-growing plants, which have never yet, I believe, been cultivated successfully, as

they only produce after many years slender stems which can never be utilised for rubber production. They seem equally slow-growing in the forests, but in dense jungle eventually produce stems several inches through. As a jungle product, the rubber-vines have a value, but as cultivated plants practically none. There is no difficulty at all in obtaining botanical information on Mr. Nash's marvellous *Urceola*. He has only to send specimens with fruit and flowers to any one of the botanists at Kew, Calcutta, or Singapore, and he can get full information. As no plant answering his description is known, and it is very improbable that any number of rubber-vines have been introduced into Bangkok, it is more than "*possible* that the plant is indigenous" to Siam it is certain.

As of late years a great deal has been discovered and published as to the cultivation and methods of preparation of all kinds of rubbers, it is very much to be regretted that such misleading articles as the one quoted should be published.

HENRY N. RIDLEY,
Director of Gardens, Straits Settlements.

[The statements criticised by Mr. Ridley are taken from the Report of Mr. Paul Nash, United States Consul-General at Bangkok, Siam ; No. 1,983 of the series of reports issued by the United States Department of Commerce and Labour.]

NOTES ON BOOKS.

CHINESE ART. By Stephen W. Bushell, C.M.G., B.Sc., M.D. Vol. I. (Board of Education, South Kensington, Victoria and Albert Museum), London.

Dr. Bushell, a diligent collector of Chinese books relating to antiquities and art industries, after a residence of thirty years in Peking, has, at the desire of the Board of Education, written a handbook on "The Art and Industries of China," of which the first volume has just appeared. This is devoted to sculpture, architecture, bronze, carving in wood, ivory, horn, &c., lacquer, and carving in jade and other hard stones. In the second volume the following subjects will be treated :—Pottery, earthenware, stoneware, and porcelain ; glass ; enamels : cloisonnés, champlevés ; and painted jewellery ; textile fabrics and embroidery ; pictorial art.

Although the mythical and legendary periods of Chinese history carry us back to a very early date, there are no relics of carved stone in China to be compared in importance or antiquity with the ancient monuments of Egypt, Chaldea and Susa, in fact the origin of sculpture in stone is very obscure in spite of all that has been written on the subject, in native as well as foreign books. Dr. Bushell says that calligraphy is a branch of fine art in China, and the penman who can write elegantly in sweeping lines with a flowing brush is ranked above the artist. The highest reverence is also paid to any ancient relics of stone and bronze with inscriptions. The most cherished relics of the Chou dynasty (B C. 1122-249) are ten stone drums, now installed in the two side halls of the principal gateway of the Confucian Temple at Peking, where they were placed in the year 1307 by Kuo Shou-Ching, the famous minister and astronomer of the reigns of Kublai Khan and his successor. They were really mountain boulders chiselled into the shape of drums, about three feet high.

With respect to Chinese architecture, the author says that the first impression of a general view of buildings is that of a certain monotony resulting from the predominance of a single type of architecture. China, in every epoch of its history, and for all its buildings, has kept to a single architectural model.

From the earliest antiquity the Chinese are recorded in their annals and traditions to have been acquainted with the art of moulding and chiselling bronze. The proportions of copper and tin employed in the fabrication of bronze objects during the Chou dynasty referred to above, are found in a contemporary work on the industries of the period.

Lacquer has furnished material for one of the earliest industrial arts of the Chinese, but no records of its development from a preservative for woodwork, to its culminating point as a medium for artistic work of the highest order remain. There are three processes in the manufacture of lacquer. The first is the preparation and coloration of the lac, the second, its application by spatula and brush in successive layers never less than three nor more than eighteen, waiting for each layer to dry before the next is put on ; the third, the decoration of the lacquered surface with artistic designs painted with the brush, worked in sensible relief or carved and modelled in the soft ground before it has cooled. This interesting account of Chinese art from the earliest times is fully illustrated.

THE CULTIVATION AND PREPARATION OF PARA RUBBER. By W. H. Johnson, F.L.S., Director of Agriculture, Gold Coast Colony, West Africa. London : Crosby, Lockwood and Son.

In consequence of the insufficiency in the supply of India-rubber to meet the constantly enlarging demands, great attention is being paid to increased cultivation in qualified areas. The author of this book was commissioned by Government in 1902 to visit Ceylon to study the methods employed there in the cultivation and preparation of Para rubber and other agricultural staples for market with a view to introduce them into West Africa. He notes that although the cultivation of Para rubber is at the present time almost limited to a few countries in the Eastern Tropics of the Old World, there is every prospect of its being further extended in those regions and also of being taken up largely in the Western Tropics. There are, he adds, in tropical

Africa thousands of square miles of land suitable for the cultivation of the Para rubber-tree. Upon a large extent of this land rubber-producing plants were at one time abundant, but now year by year their number is being gradually diminished, as the result of the disastrous methods of tapping employed by the native rubber collectors.

It is estimated that the world's annual consumption of rubber is about 60,000 tons, valued at about £16,000,000. In 1830 the amount of rubber imported into the United Kingdom was 460 cwts., and in 1903 it was 486,105 cwts., valued at £6,742,966.

The trees producing Para rubber furnish abont one-third of the world's supply. They belong to the genus *Hevea*. The author remarks that while the demand for rubber continues to increase, the supplies from some sources are steadily decreasing. This is especially the case from different parts of Africa, which furnish a considerable portion of the world's supply,

The rubber prepared from cultivated trees is generally rated at a higher market price than that collected from wild trees in consequence of its greater purity. The loss from "fine" Para is from 10 to 15 per cent. in manufacture, whereas that from the "biscuit" rubber prepared from Para cultivated rubber trees is generally less than 1 per cent. Mr. Johnson has given separate chapters on the cultivation of the tree; insect pests and fungoid diseases (in which he says that no disease has up to the present time been discovered to seriously affect this tree under cultivation); collecting the rubber; preparation of rubber from the latex; yield of Para rubber from cultivated trees; establishment and maintenance of a Para rubber plantation; and the last chapter deals with the commercial value of the oil in Hevea seeds. Here the author states, "In addition to supplying the market with the finest quality of rubber, cultivators of *Hevea brasiliensis* will be in a position to compete in that enormous market which provides the world with vegetable oils."

LABORATORY STUDIES FOR BREWING STUDENTS. By Adrian J. Brown. London: Longmans, Green and Co.

The author of this work, who is the Director of the School of Brewing and Professor of the Biology and Chemistry of Fermentation at the University of Birmingham, finding the want of a suitable text-book, has published the course of laboratory studies which he had proposed for the use of his students. It is intended for the use of students who have already obtained a sufficient knowledge of chemistry, and are attending lectures under a competent instructor.

The first section deals with barley and malting, the anatomy of the barley corn, changes in barley during fermentation, and the chemical analysis of malt. The second section is concerned with the principles of the mashing process, the hydrolysis of starch, analysis of brewing sugars. Section III. is devoted to fermentation, and Section IV. to the hop.

GENERAL NOTES.

GERMAN CEMENT.—In 1852 there was discovered on the coast of the Prussian province of Pomerania the same kind of clay ("Septurien-Thon") used in the United Kingdom in the preparation of cement. This discovery was followed by the establishment ot experimental cement works at Zülchow, near Stettin, where the newly-discovered clay, together with chalk, found in the neighbouring island of Wollin, was used for the manufacture of cement, which was pronounced to be equal in quality to Portland. Thirty years later there existed in Germany 420 factories of cement and cement goods, with a total output of 3,050,000 casks (of 374 lbs. each). In 1895, the annual output had increased to 12,400,000 casks, and the number of cement works to 1,136 larger and 138 smaller factories of cement and cement goods, employing 29,896 persons. No official statistics of the number of cement and other industrial works, and the number of persons employed in different German industries, have been published since 1895, but there can be no doubt that the number of cement works in Germany has largely increased during the last nine years. Sir William Ward, in his Report just published (Diplomatic and Consular Reports No. 624), puts the present output at 30,000,000 casks, or much more than double the quantity produced in 1895. Gradually German cement has become an important article of export from Germany, and it seriously competes with British cement in most foreign countries, and, to a certain extent, even in the United Kingdom itself. But the value of the imports to England is a diminishing quantity, as shown by the following figures, giving the imports for the three years 1901-3:—1901, £58,700; 1902, £50,350; 1903, £45,850. By far the best customer of Germany has been the United States, which in 1902 took cement to the value of £370,000. But in 1903 the value fell to £277,050. Notwithstanding the general growing consumption of cement in the United States the American cement industry is rapidly becoming able to satisfy the home demand. Up to the end of last century the German cement industry was in a very prosperous condition, the average dividend paid by all the larger cement works in 1899 amounting to 17 per cent. In 1900 it fell to 12 per cent., and since then over-production has had disastrous effects.

COTTON GROWING IN THE WEST INDIES.—The efforts made to resuscitate the cotton industry in British Guiana have not yet given results that can be said to be encouraging. The experiments tried, says the Colonial-office report just issued (Cd. 2238), have shown that the soil on the coast-lands of the colony at present under cultivation—a heavy clay—is unsuited for the growth of sea island cotton, and should a suitable variety be found there will remain the labour problem to be faced if the cultivation is to be

undertaken on a large scale. Climatic conditions require that planting shall be done so that the ripening may take place from the latter part of August to the end of November. But in this period the bulk of the sugar and rice crops of the colony are reaped and labour is in good demand. The cost of labour is higher then in the islands, and though cotton was at one time profitably grown in Guiana it remains to be demonstrated whether it can be so grown under present labour conditions. In Trinidad and Tobago, which owe so much in recent years to the cultivation of cocoa, nothing apparently is being done to introduce cotton cultivation. More attention has been given to the question in St. Lucia, but "for a number of reasons," writes Sir George Melville, reporting to Governor Sir R. B. Llewelyn in November (Cd. 2238), "our planters have not seemed disposed to regard the revival of the industry in the colony with favour. One of the difficulties which presented itself was the selection of a variety of cotton to suit the varying conditions of soil in different localities." However, the cultivation is now being more readily taken up, and the efforts of the British Cotton Association may be expected to result in some increase in the area under cultivation, which at present is only about 500 acres.

Dust-Destructors and Electric Lighting.—In his Cantor lectures, in 1892, on the "Development of Electrical Distribution," Professor George Forbes stated that if all the refuse then collected in Paddington were properly burnt and used in the most economical way, it would provide enough electricity to light one 8-candle power lamp for two hours every night of the year for each of the inhabitants. This is referred to in the *Builder*, in connection with a paper read by Mr. W. P. Adams to the Institution of Electrical Engineers, on the question of the combination of dust-destructors with electricity works. We learn from this paper that the results obtained at Hackney and Fulham practically do all that Professor Forbes prophesied, and in a few years even better results will be obtained. Mr. Adams calculates that approximately one million tons of refuse are collected every year in London, most of which is taken out to sea by barges at considerable expense to the ratepayer. On a moderate estimate, the value of the potential capacity of this refuse for steam raising for electric engines is £100,000 per annum. The author shows that, with the improved dust-destructors now in use, there is a substantial gain, in most cases, in combining dust-destructor and electricity works. The exceptional cases are when the refuse has a very low calorific value. At Llandudno and at Royton, in Lancashire, for example, the refuse is of little use for steam raising. It is curious to note that the dust of the greatest calorific value comes from poor neighbourhoods. At Bermondsey its value is particularly high. Mr. Adams suggests that the explanation is that the working-classes, unlike the middle-classes, rarely sift their ashes. In considering the question of dust-destructors, the first point to be settled by municipalities, therefore, is the heating value of the refuse collected. This can be determined experimentally without much difficulty, and the value remains wonderful constant in a given neighbourhood. The revenue earned by a dust-destructor is due mainly to the supply of steam to the electricity works, but this steam can be sold for many other purposes as well.

The London County Council Scholarship Scheme.—In commenting on the County Council Scholarship scheme, then just made known, attention was directed (see *Journal*, December 16th) to a memorandum to the Committee presented by the London Teachers' Association, in which it was said, "the great blot in the whole scheme appears to be the desire to secure candidates for the teaching profession rather than to improve the general education of the children." The County Council reassembles on the 24th, when it will resume the discussion of the scheme, and the signs point to its critics directing their main attack against the attempt to meet the dearth of teachers through the agency of scholarships. That the authors of the scheme wish to use it mainly for this purpose is admitted, for they say in their report, "The total number of scholars selected must be largely increased. This will not really be an increase in the scholarship system as hitherto understood, but is made necessary by the recent Board of Education orders as to pupil teachers." And to this the London County Council Finance Committee adds, "We understand one of the chief ideas underlying the scheme is that it will aid in increasing the supply of adult teachers." It is urged by its opponents that the scheme is too much of a "teacher catching" project, that children from very poor homes could not, under the conditions sought to be imposed, any longer win scholarships, or if they did they cannot benefit by them. "For the great bulk of the children of the artisans," writes Dr. Macnamara, M.P., "we want scholarships that can produce high-grade mechanical, electrical engineering, and business workers. We have too many scholarship-trained clerks already." It will be interesting to have the answer of the framers of the scheme.

Technical and Industrial Education in Bengal.—The latest issue of the *Calcutta Gazette* gives the report of the head of the department on Public Instruction in Bengal for 1903-1904, and after dealing with female education, and the lack of suitable teachers for many classes of schools, the new scheme, which has been drafted for the purpose of improving technical education in the province, is described. Schools are to be established for the purpose of imparting instruction in respect of the best and latest methods of cotton, silk, and wool weaving. It is well known that a great hand-loom industry exists in Bengal. Its condition is, however, precarious; and

it is considered essential, that if it is to be saved from sinking further into decay, really practical technical instruction should be provided for all classes of weavers, except the very small number who are employed in artistic work, to which mechanical improvements are not applicable. The great mass of Indian weavers still use the old Indian hand-loom, and warping apparatus, and are ignorant of the extraordinary mechanical improvements which have been made, since the middle of the eighteenth century, as regards these appliances, and the preparatory processes of weaving. Several of the most important of these improvements are inexpensive and do not require great technical skill, and can easily be adapted to ordinary Indian weaving.

CANADIAN ENGINEERING.—At the conclusion of the address descriptive of the visit of English engineers to America, which Sir William White delivered on Tuesday last to the Institution of Civil Engineers, he said that:—The development of the Dominion of Canada was in an early stage, but those charged with the responsibility of government were fully alive to the grandeur of its resources and its potential greatness. The realisation of this policy depended largely upon the execution of engineering works of enormous magnitude. Those who took part in this visit had but a glimpse of what was being done to utilise the natural advantages of the country, but enough was seen to make it certain that in Canada was to be found a splendid field for British enterprise and capital. Canadian engineers without exception expressed the hope that in the organisation and conduct of the great works now contemplated or to be undertaken hereafter they would have the assistance of British engineers and especially of young engineers. No better school for aspirants in the profession could be found than that afforded by the Dominion. What was true of Canada was true also of our other Colonies and Dependencies, and it might be hoped that British enterprise and capital would be more devoted in the future to the development of the resources of the British Empire, and less to corresponding work in foreign countries.

CANAL BOAT CHILDREN.—The report of the Board of Education for the year 1903-4 contains the following information respecting the education of canal boat children:—"The conditions of school attendance in the case of children living in canal boats remain very much as they have been in previous years. The effective enforcement of the Education Acts as concerns these children is necessarily difficult. Although the various school boards and school attendance committees appear to have discharged their duties so far as circumstances permitted, the result was, and must always be, unsatisfactory owing to the facts that the boats are constantly moving from one town to another, and that many boats rarely, if ever, revisit their place of registration. Possibly the difficulty will be in part remedied by the wider authority of the county councils under the Acts of 1902 and 1903. As in previous years, several authorities urge that it should be made illegal for children under fourteen years of age to reside on canal boats. It is, however, satisfactory to find that in most districts it is becoming unusual for either women or children to live permanently on the boats. We hope that the boat owners may be induced generally, as they have already been in some cases, to co-operate by forbidding their workmen to take their families with them."

WATER POWER FOR IRON ORE SMELTING IN CANADA.—In the *Journal* of December 9th, the report of the Canadian Commission on the electrothermic manufacture of iron and steel was reviewed, and mention made of Dr. Haanel's citation of the Chats Falls, near Ottawa, as offering exceptional facilities for the generation of cheap power. These falls are situated on the Chats River, and are 28 miles west of Ottawa. At low water the available head is 41 feet, and the minimum flow 1,200,000 cubic feet per minute. At high water the maximum flow exceeds 7,500,000 cubic feet per minute. The Canadian Government has under consideration a proposal for damming up the lakes so as to give a mean minimum flow of 2,500,000 cubic feet per minute. This would give 170,000 horse-power, if used for generating electricity. It is stated that the natural facilities are such that the power can be developed at an unusually low capital cost. It is hoped that a direct and immediate result of the report of the Commission will be the erection of works for the electrical reduction of iron ore. The plant initially contemplated would be one of 18,000 horse-power, of which 16,000 horsepower would be used for smelting the ore, the remainder being used for power and lighting.

THE COST OF JUSTICE.—A return relating to the High Court of Justice and the Court of Appeal, just issued, gives the cost of these Courts to the country for the year ended 31st March, 1904. The total receipts amounted to £508,121 13s., the total expenditure to £622,877 4s. 6d., leaving a deficit of £114,755 11s. 6d. The largest item under the head of receipts is "fees received in the district registries of the High Court," £21,286 0s. 8d., and the next, "Lunacy percentage account fees," £16,284. The salaries of the Judges, including that of the Lord Chancellor (£6,000) amounted to £155,000, and £22,949 14s. 7d. was paid on account of retiring annuities of Judges. The circuit expenses of the Judges came to £11,261 12s.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock:—

JANUARY 18.—"Wireless Telegraphy and War Correspondence." By CAPTAIN LIONEL JAMES. SIR WILLIAM HENRY PREECE, K.C.B., F.R.S., will preside.

JANUARY 25.—"London Electric Railways." By the HON. ROBERT P. PORTER.

FEBRUARY 1.—"The Navigation of the Nile." By SIR WILLIAM H. PREECE, K.C.B., F.R.S. SIR ROBERT HANBURY BROWN, K.C.M.G., will preside.

FEBRUARY 8.—"Time Development in Photography, and Modern Mechanical Methods of carrying it out." By R. CHILD BAYLEY. GEORGE DAVISON will preside.

FEBRUARY 15—

FEBRUARY 22.—"Some Misconceptions of Musical Pitch." By JOHN E. BORLAND. (*a*) *Visual*—due to conventional but inaccurate notation; (*b*) *Aural*—volume of tone mistaken for depth, brightness for height.

Illustrated by voices, instruments and diagrams.

MARCH 1.—"The British Art Section of the St. Louis Exhibition." By ISIDORE SPIELMANN. SIR EDWARD POYNTER, Bart., P.R.A., will preside.

Dates to be hereafter announced:—

"The Protection of Buildings from Lightning." By KILLINGWORTH HEDGES, M.Inst.C.E.

"The Present Aspect of the Fiscal Question." By SIR CHARLES MALCOLM KENNEDY, K.C.M.G., C.B.

"British Woodlands." By the RIGHT HON. SIR HERBERT MAXWELL, Bart., M.P.

"The Supply of Electricity." By JAMES NELSON SHOOLBRED, B.A., M.Inst.C.E.

"Lake Baikal and its Connection with the Great Siberian Railway." By ARTHUR GULSTON.

"Application of Electricity to the Location of Mineral Deposits." By ALFRED WILLIAMS.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

JANUARY 19.—"The Gates of Tibet." By DOUGLAS W. FRESHFIELD. SIR WILLIAM LEE-WARNER, K.C.S.I., will preside.

FEBRUARY 16.—"The Indian Census of 1901." By SIR CHARLES A. ELLIOTT, K.C.S.I., LL.B. The RIGHT HON. LORD GEORGE HAMILTON, G.C.S.I., M.P., will preside.

MARCH 16.—"Manipur and its Tribes." By T. C. HODSON (late I.C.S.).

APRIL 6.—

MAY 11.—"The Manufactures of Greater Britain. —III. India." By HENRY JOHN TOZER, M.A.

COLONIAL SECTION.

Tuesday afternoons at 4.30 o'clock:—

JANUARY 24.—"British Commercial Prospects in the Far East." By BYRON BRENAN, C.M.G., late H.B.M. Consul-General at Shanghai. SIR EDWARD A. SASSOON, Bart., M.P., will preside.

FEBRUARY 28.—"The Manufactures of Greater Britain.—I. Canada." By C. F. JUST, Canadian Government Service in London.

MARCH 28.—The Manufactures of Greater Britain. —II. Australasia." By the HON. WALTER HARTWELL JAMES, K.C., Agent-General for and late Premier of Western Australia.

MAY 23.—"The Cape to Cairo Railway." By SIR CHARLES H. T. METCALFE, Bart., M.Inst.C.E.

APPLIED ART SECTION.

Tuesdays, at 4.30 or 8 o'clock:—

JANUARY 31, 8 p.m.—"Calligraphy and Illumination." Two Papers. By EDWARD JOHNSTON and GRAILY HEWITT. LEWIS FOREMAN DAY, Vice-President of the Society, will preside.

FEBRUARY 21, 8 p.m.—"The Queen Victoria Memorial as compared with other Royal Memorials." By MARION H. SPIELMANN. JOHN BELCHER, A.R.A., President of the Royal Institute of British Architects, will preside.

MARCH 21, 8 p.m.—"West Country Screens and Rood Lofts." By F. BLIGH BOND, F.R.I.B.A. G. F. BODLEY, R.A., will preside.

APRIL 11, 4.30 p.m.—"The Monumental Treatment of Bronze." By J. STARKIE GARDNER. SIR GEORGE BIRDWOOD, K.C.I.E., C.S.I., will preside.

MAY 16, 4.30 p.m.—"Popular Jewelry." By MONSIEUR LALIQUE (Paris).

CANTOR LECTURES.

Monday evenings, at 8 o'clock:—

JAMES P. MAGINNIS, Assoc.M.Inst.C.E., M.Inst.Mech.E., "Reservoir, Stylographic, and Fountain Pens." Three Lectures.

LECTURE I.—JANUARY 23.—*Ancient Writing Implements.*—The Stylus and Tabula—Calamus or reed pen—Stencil—Quills, quill nibs, attempts to make quills more serviceable—Substitutes for quills—Silver pens—Ink horn and penner—Ancient writing outfit—Eastern writing implements—Survival of ink horn—Japanese writing box and pens—Their portable writing set—Early metal pens—Steel pens—Barrel pens—First patent for metallic pens—Improvements in steel pens with the object of increasing their ink-holding capacity—Reservoir nibs, various illustrations.

LECTURE II.—JANUARY 30.—*Stylographic Pens.*—Rudimentary forms—Early patents—Rigid points, needle points—Various writing or marking pens—Modern Stylographic pens, Nota Bene, Cygnet, and others—Gold pens, description of manufacture.

LECTURE III.—FEBRUARY 6.—*Fountain Pens.*—Early patents—Solid ink—Various reed arrangements—Self-filling, reservoirs, flexible reservoirs, piston and plunger—Modern types of Fountain pens, Swan, Ideal, Conklin, Pelican, Unleakable, Wirt, Quill, Post, Autofiller, Fleet, &c.

DUGALD CLERK, "Internal Combustion Engines." Four Lectures.

February 13, 20, 27, March 6.

HERBERT LAWS WEBB, "Telephony." Four Lectures.
March 13, 20, 27, April 3.

ALAN S. COLE, C.B., "Some Aspects of Ancient and Modern Embroidery." Two Lectures.
May 1, 8.

HENRY WILLOCK RAVENSHAW, Assoc. M.Inst.C.E., Mem.Fed.Inst.Min.Eng., "The Uses of Electricity in Mines." Two Lectures.
May 15, 22.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JAN. 16...Optical, 20, Hanover-square, W., 8 p.m. Messrs. S. D. Chalmers and H. S. Ryland, "A Method of Testing Prisms."

Surveyors, 12, Great George-street, S.W., 8 p.m. 1. Mr. A. R. Stenning, "Urban and Rural District By-Laws, with Suggested Amendments." 2. Mr. William Menzies, on the same subject.

Camera Club, Charing-cross-road, W.C., 8½ p.m.

Victoria Institute, 8 Adelphi-terrace, W.C., 4½ p.m. Colonel T. Holbein Hendley, "The History of Rajputana."

London Institution, Finsbury-circus, E.C., 5 p.m. Dr. W. Evans Darby, "The History of International Arbitration."

TUESDAY, JAN. 17...Royal Institution, Albemarle-street, W., 5 p.m. Prof. L. C. Mayall, "Adaptation and History in the Structure and Life of Animals." (Lecture I.)

National Service League, Caxton-hall, Westminster, S.W., 5½ p.m. Mr. G. G. Coulton, "The Moral and Educational Advantages of Universal Naval and Military Training."

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Mr. Leveson Francis Vernon-Harcourt, "The River Hooghly."

Statistical, 9, Adelphi-terrace, W.C., 5 p.m. Mr. Reginald Dudfield, "A Critical Examination of the Methods of Recording and Publishing Statistical Data bearing on Public Health, with Suggestions for the Improvement of such Methods."

Pathological, 20, Hanover-square, W., 8½ p.m.

Zoological, 3, Hanover-square, W., 8½ p.m. 1. Mr. W. F. Lanchester, "A Collection of Sipunculids made at Singapore and Malacca." 2. Mr. W. F. Lanchester, "A Collection of *Gephyrea* from Zanzibar." 3. Mr. W. F. Lanchester, "The Sipunculids and Echiurids collected during the 'Skeat Expedition' to the Malay Peninsula." 4. Mr. A. D. Imms, "The Oral and Pharyngeal Denticles of Elasmobranchs." 5. Mr. F. E. Beddard, "A Contribution to the Anatomy of *Chlamydosaurus* and some other *Agamidæ*." 6. Mr. F. E. Beddard, "A Note on the Brain of *Cynopithecus niger*."

Colonial Inst., Whitehall Rooms, Whitehall-place, S.W., 8 p.m. Mr. E. A. S. Harney, "Imperialism from an Australian Standpoint."

WEDNESDAY, JAN. 18...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Captain Lionel James, "Wireless Telegraphy and War Correspondence."

Meteorological, 25, Great George-street, S.W., 7½ p.m. Annual General Meeting. Address by the President (Captain D. Wilson-Barker), "The Connection of Meteorology with other Sciences."

Geological, Burlington-house, W., 8 p.m.

Microscopical, 20, Hanover-square, W., 8 p.m. Annual Meeting. Address by the President, "What were the Carboniferous Ferns?"

Chemical, Burlington-house, W 5½ p.m. 1. Mr. F. D. Chattaway, "Nitrogen Halogen Derivatives of the Sulphonamides. Part I.—Sulphondichloroamides and Sulphonalkylchloroamides." Part II.—"Sulphondibromoamides and Sulphonalkylbromoamides." 2. Mr. H. D. Law, "Electrolytic Oxidation of Aliphatic Aldehydes." 3. Messrs. G. T. Morgan and F. M. G. Micklethwait, "The Diazo-derivatives of the Benzenesulphonylphenylenediamines." 4. Messrs. S. E. Sheppard and C. E. K. Mees, "The Molecular Condition in Solution of Ferrous Potassium Oxalate." 5. Mr. W. C. Anderson, "The Formation of Magnesia from Magnesium Carbonate by Heat, and the effect of Temperature on the Properties of the Product." 6. Mr. K. J. P. Orton, "Transformations of Derivatives of s-tribromodiazobenzene." 7. Mr. A. W. Stewart, "The Addition of Sodium Bisulphite to Ketonic Compounds."

Entomological, 11, Chandos-street, W., 8 p.m. Annual Meeting. Address by the President, Professor E. B. Boulton.

British Archæological Association, 32, Sackville-street, W., 8 p.m.

Society of Dyers and Colourists, 608, Birkbeck Bank Chambers, W.C., 8 p.m. 1. Mr. F. J. Farrell, "Production of Crepon Effects on Silk Fabrics by Chemical Means." 2. Mr. Fredk. Hewitt, "The Dyer: His Trade and Position."

Journal of the Society of Arts.

No. 2,722. VOL. LIII.

FRIDAY, JANUARY 20, 1905.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

NOTICES.

NEXT WEEK.

MONDAY, JANUARY 23, 8 p.m. (Cantor Lecture.) JAMES P. MAGINNIS, "Reservoir, Stylographic and Fountain Pens." Lecture I.

TUESDAY, JANUARY 24, 4.30 p.m. (Colonial Section.) C. F. JUST, "The Manufactures of Greater Britain.—I. Canada."

WEDNESDAY, JANUARY 25, 8 p.m. (Ordinary Meeting.) The HON. ROBERT P. PORTER, "London Electric Railways."

Further details of the Society's meetings will be found at the end of this number.

INDIAN SECTION.

Thursday afternoon, January 19th; Sir WILLIAM LEE-WARNER, K.C.S.I., in the chair.

The paper read was "The Gates of Tibet," by DOUGLAS W. FRESHFIELD.

The paper and report of the discussion will be published in a future number of the *Journal*.

PORTRAIT OF SIR F. BRAMWELL.

With this number of the *Journal* is issued, as a Supplement, a reproduction of the portrait of the late Sir Frederick Bramwell, by Mr. Seymour Lucas, R.A., which was presented to the Society by Mr. Henry Graham Harris last November, and now hangs in the Council Room. (See *ante*, November 25, 1904, p. 19.)

A small number of extra copies of the portrait have been printed, and a member wishing to bind the portrait with the *Journal* can have a copy on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

SIXTH ORDINARY MEETING.

Wednesday, January 18th, 1905; Sir WILLIAM HENRY PREECE, K.C.B., F.R.S., Vice-President of the Society, in the chair.

The following candidates were proposed for election as members of the Society:—

Abrams, Herbert John Sinclair, Hutton Mount, Pattison-road, Child's-hill, N.W.
Adams, Alfred Adam, 16 and 17, Devonshire-square, E.C.
Bevan, William, A.R.I.B.A., Chief Government Architect, Public Works Department (P.O. Box 398), Government Buildings, Pretoria, South Africa.
Erikson, Anthony, Assoc.I.N.A., 20, Hummum-street, Fort, Bombay, India.
Evans, Captain Thomas Luther, 59, Broad-street, Bristol.
Fernandez, George Anthony, 43, Raffle's-place, Singapore, Straits Settlements.
Frick, Henry Edgeworth, care of Fore River Shipbuilding Company, Quincy, Massachusetts, U.S.A.
Harwin, Albert Edward, Church-street, Pietermaritzburg, Natal, South Africa.
Hoare, Frederick, 251-254, High Holborn, W.C.
Hynd, John, Consolidated Goldfields of South Africa, Ltd. (Box 67), Bulawayo, Rhodesia, South Africa.
Kelly, John Forrest, Ph.D., Pittsfield, Massachusetts, U.S.A.
Kerr, David Gillespie, The Canada Corundum Company, Ltd., Craigmont, Ontario, Canada.
Khras, Minocher Jamshed Sohrab, Khras Bungalow, Middle Colaba, Bombay, India.
Kingston, C. Burrard, M.Inst.M.M., The Evancon Gold Mining Company, Ltd., Verrés, Val d'Aosta, Italy.
Landau, Miss Dorothea, 30, Bryanston-square, W.
Legardo, Vicente L., 208, Mason street, San Francisco, California, U.S.A.
Morris, Rev. E. C., D.D., Ph.D., Helena, Arkansas, U.S.A.
Morrison, Charles, 53, Coleman-street, E.C.

Muir, David Temple, Pentlands, Castlebar-road, Ealing, W.
Oliveri, Joseph Giammusso, A.R.S.M., A.I.E.E., Caltanissetta, Sicily.
Pain, Robert Tucker, J.P., Ryll-court, Exmouth.
Pollock, George Frederick, Hanworth, Middlesex.
Reid, William Lewis, 160, Green-lanes, Clissold-park, N.
Roberts, Cyril, 1, Rossetti Studios, Flood-street, Chelsea, S.W.
Roberts, Richard Penberth, M.Inst.MM., Concession de Tama, Vezzani, Corsica, France.
Robertson, James Barr, The Oriental Club, Hanover-square, W.
Schäfer, Henry Thomas, 40, Brewer-street, Golden-square, W.
Suratwâllá, Dr. Ardeshir Bamanjee, Chira Bazar, Bombay, India.
Thomas, Hon. J. J., M.L.C., J.P., Wilberforce-house, Sierra Leone, West Africa.
Trevett, Charles G., A.M.I.E.E., Messrs. Green and Trevett, 15, Castle-street, Cape Town, South Africa.
Tully, John Collingwood, F.R.I.B.A., Ardernes-chambers, Longmarket-street, Cape Town, South Africa.
Wecksley, Felix S., Bangalore, India.
Wedlake, George, Royston, St. Margaret-at-Cliffe, Kent.
Wright, Allister MacLean, 62, Harman-street, Addington, Christchurch, New Zealand.

The following candidates were balloted for and duly elected members of the Society:—

Dale, Hylton William, 8, Chalcot-gardens, Belsize-park, N.W.
Ertz, Edward Frederick, R.B.A., Polperro, Cornwall.
Fletcher-Watson, P., R.B.A., Ashleigh, Paignton, South Devon.
Lee, Sydney, 6, The Studios, Holland-park-road, Kensington, W.
Lim Chin Tsong, 47, China-street, Rangoon, Burma.
Stell, Samuel Fenton, F.C.S., 25, Henry-street, Keighley, Yorkshire.
Townend, Frederick Bedborough, 11, Queen Victoria-street, E.C., and Brentwood, Essex.

The paper read was—

WIRELESS TELEGRAPHY AND WAR CORRESPONDENCE.

By Captain Lionel James.

It is with considerable diffidence that I presume to address you this evening upon a subject of which I have no scientific knowledge. But Sir William Preece has been kind enough to encourage me in the belief that you will be indulgent if during the evening I make slips or miscalculations which may offend the sensitiveness of your expert ears. I may preface my remarks by saying that I know nothing at all about wireless telegraphy But during the early months of last year, as a humble servant of *The Times*, I was entrusted with the carrying out of a scheme in which wireless telegraphy played an important part. Therefore you must not expect me to do more than tell you, how, when my expert advisers gave me guarantees with regard to conditions and distances, I was able to apply the scientific apparatus for which they were responsible, to the needs and necessities of *The Times* newspaper. For six months a portion of *The Times* correspondence found its way to the London office by the means of wireless telegraphy, and, to use a perhaps not inadequate simile, during this period as far as the wireless service was concerned, Dr. de Forest supplied the drawing, while I was responsible for the frame.

Five years ago I commenced to take an interest in the results which were being attained by wireless telegraphy, for it seemed certain that, sooner or later, occasion would arrive when it would be practicable to apply to journalistic enterprise this marvellous adjunct to the world's system of communication. The war correspondent is not usually modest, and we have seen many accounts of the ingenuity which members of this small craft have employed to enable their journals to publish, in as short a time as possible after the event, a graphic account of some sensational episode. Although I belong to the young school of correspondents, even within my small experience I have seen the employment of cut-throat Pathans, Ethiopians, bicycles, pigeons, camels, horses, skin-floats, heliographs, bottles, field telegraph wires, boats, flags, &c., as a means of hastening news to the correspondent's essential, the submarine cable. Some of these endeavours necessitated great expense, others considerable personal sacrifice. Therefore there had always remained at the back of my mind an idea that much of the labour, much of the risk and loss, and not least, perhaps, much of the personal discomfort might be avoided by the use of the scientific progress made in the experiments with the Hertzian waves. The fact that I had entered upon my profession during a cycle which found me in constant active employment prevented me from making as close a study of these scientific results as I might have desired; it did not, however, prevent me from attempting a comparison in the results obtained. The

recital of a journey to the Isle of Wight, of three days spent in following a German military wireless telegraphy waggon, of conversation with torpedo lieutenants in the British navy, of a voyage to America when most of my leisure was passed in the wireless chamber of the liner, would be wearisome. It was not until I saw evidences of the success which Dr. de Forest had attained in the field of American Press rivalry during the yacht races in the summer of 1903 that I realised that the time would soon be at hand to present a feasible scheme to my employers.

Our old friend the Balkans claimed my presence when Dr. de Forest was carrying out his experiments between Holyhead and Ireland the year before last. But by great good fortune the mail steamer, which a month later was taking Dr. de Forest back to his labours in the United States, also carried me and my capable colleague, Mr. David Fraser, towards the war cloud gathering in the Far East. This fortunate meeting enabled me to discuss the minute detail with regard to the application of his system to the purposes in hand. The department in *The Times* office which deals with war, and naval and military subjects, had, when I was present at their last meeting, the evening before sailing to the Far East, forecast with great accuracy the area which would cover the most important of the early land and sea operations. If you will follow me a moment on this chart of the Yellow Sea and the Gulf of Pe-chili (p. 207), you will see at once of what value a moving station would be to us if equipped with wireless telegraphy. It is the avowed intention of the de Forest Company, at least, so I understand, to act, not as the rival of the cable companies, but as the auxiliary. And this was the use for which *The Times* desired wireless telegraphy—to act as an auxiliary to its cable service. You will see that in making a choice of a receiving station I had to consider the distances that it would be necessary to cover in reaching the cables. The Shangtung province at once suggests itself. Here we have two cable stations, namely, Wei-hai-wei and Chifu. For reasons which I think are obvious to all of you in this room I selected Wei-hai-wei. Dr. de Forest promised me that if I succeeded in erecting a mast 180 feet in height on the China coast and used it in conjunction with a moveable station which showed an exposure of at least 120 feet of wire, that he would supply me with a set of apparatus and expert operators who would transmit messages with accuracy for 160 miles. At New York I was able to place this proposition before my employers. I need not tell you that *The Times* has always given its great support to all matters of scientific research and experiment. After due consideration of the scheme they authorised me to make the necessary arrangements for carrying it into practice.

As you are all aware, events in the Far East during January last year were moving rapidly towards war. Therefore every despatch had to be made in order that we might be in time for the opening of the campaign. I left San Francisco for Yokohama on the 5th of January, and a fortnight later the de Forest Company had started off after me a complete apparatus for two stations with the necessary complement of expert operators.

On arriving in Japan, my colleague, Mr. Fraser, was without delay despatched to Wei-hai-wei to commence the building of the receiving station. It is interesting to notice here that he caught the last steamer which sailed from Fusan to Chifu before the passenger service in the Yellow Sea between Japan, Korea, and China became disorganised.

On the Pacific liner we had talked airily of constructing a receiving station that would give us a 180 feet exposure of wire. Nautical men told us it was as simple as falling off a log. Engineers with a knowledge of China advised us to build a bamboo structure, which they said any Chinese contractor would raise in a few days. It is one thing to run up a mast when you have every appliance within reach or to build a bamboo structure in a Treaty port where Chinese contractors are falling over each other, but it is a very different thing, as Mr. Fraser found, to construct a receiving station on a bleak island off the coast of China when little or nothing in the way of appliances is at hand.

I will not weary you here by giving you a minute description of the troubles which we had with that mast. All the essentials had to be brought up from Shanghai several hundred miles by sea. Once it fell and broke to pieces, another time it was blown down by a typhoon, and as for the bamboo structure of which Chinese residents had spoken so much, we found that there were no contractors falling over each other in the desire to do our bidding, and also that the Chinese were not in the habit of building these structures in the Shan-tung province. If I had realised the many diffi-

culties which surrounded us I am not sure that I would have been bold enough to have suggested the enterprise.

As may be readily understood the Japanese naval and military authorities looked upon the enterprise with some suspicion. They were at least far more courteous than their enemies who promised us short shrift if they should catch us. But the latter was a minor difficulty in comparison with the trouble of that mast and the handling of a 1,400-ton steamer, to say nothing of a delicate installation, which requires to be coquetted with and humoured in every weather, condition, and season.

Hostilities broke out on February 6th. The belligerents had not been considerate enough to wait for us. On February 8th the steamer containing operators and apparatus arrived at Yokohama. I had *The Times* despatch boat, the *Haimun*, waiting for this liner at Shanghai. During her wait here she had been fitted with the necessary spars to enable her to give the required exposure of wire. She left Shanghai on February 16th, the operators, as far as the weather would allow, busying themselves in commencing to fit her with the transmitting apparatus. On February 17th the *Haimun* arrived at Wei-hai-wei, and the operators were placed on shore, in order to get the receiving office in order while the *Haimun* commenced to ply between Wei-hai-wei and Chemulpo in her capacity of despatch boat. It may be mentioned here that six hours after the *Haimun* left Shanghai the whole of the wireless fixings which had been put up there were carried away by a gale of wind.

Until the end of February the operators who were also expert mechanics were hard at work in getting the station into working order. I may point out that Dr. de Forest had told me that in the United States where every appliance was to hand, they required three weeks at least to bring a station into working order. Therefore, as the apparatus only arrived at Wei-hai-wei on February 17th, we could hardly expect to have the system working before March 15th. But even in spite of the fact that a part of the machinery had miscarried during transhipment, we were able to despatch our first message from sea 50 miles outside Wei-hai-wei on March 14th.

I must here mention that although we had guaranteed to give Dr. de Forest a shore station with 180 feet exposure and 120 feet on the moving station, yet with the appliances at hand we were never able to raise more than 165 on the shore station and 105 on the boat. Therefore it was with some misgivings that we entered as a working machine. The first message that we had sent had been purely experimental, and it was not until two days later that we were able to give the system a fair chance.

We had cleared for Chenampo, in which port the ice had broken up sufficiently to allow Kuroki's army to commence landing. It was a bitterly cold journey, and when we entered the Ping-yang Inlet we had to forge our way through several miles of floating ice. We steamed up, and anchored in the middle of the Japanese transport fleet.

On the morning of the 17th we left Chenampo with valuable and exclusive information both with regard to the Japanese landing, the situation of the Russian forces on the Yalu, and of General Inouye's terrible march up from Seoul to Ping-yang. On the advice of the expert operator on the *Haimun* we did not attempt to send a message to Wei-hai-wei until we were eighty miles from our receiving station. At this distance a message was sent, and as we received no acknowledgment we steamed in and repeated the message at fifty-five miles. Then, as no acknowledgment was received, and we felt that something was wrong, we continued the journey to Wei-hai-wei. Here we found that not only had the second message been received in its entirety but that the first came in without a mistake, and before a duplicate had been sent in, was on the cables and on its way to London. It would be hard to express the relief which we felt at this result. Up to that moment there had been something of a speculative nature about the whole enterprise. And those of us who were responsible, as chapter of accident succeeded chapter of accident, could not fail to suffer from some feeling of depression. But here in the very first instance had been a success. With our but half-adjusted station we had succeeded in covering a distance of which, in their own service, the British Navy speak with pride, and which a Japanese naval expert gave me as the outside limit of the system employed in the Imperial Japanese Navy. The fact that, although our shore station was able to receive, yet it failed as a remitting station, was not only an inconvenience but a distinct flaw. But the chief expert of the de Forest Company said that if I gave him a day he would rectify this.

Although we had chosen a point for our shore station, namely, Leu-kung-tau, the

island at the mouth of the bay at Wei-hai-wei harbour (which gave us a clear arc of open sea of about 135 degrees), yet of necessity we had been obliged to erect a station some 300 feet above the sea level. This, as the scientists among you will know, was a distinct disadvantage, but the expert operator nullified this discrepancy by placing copper plates in the sea and connecting them to the station. After he had done this we had no difficulty in receiving from the station, though owing to the fact that our exposure of wire was nearly 50 feet less on the transmitting station than on the receiving station, we were never able to receive at quite the same length of distance as we were able to transmit.

We had now our system working and it only remained for us to develop it, as far as its limitations would allow, to its full uses for journalistic reporting. The operators were confident that we should be able to cover one hundred miles, and, at that period, being quite ignorant as to the distance we should eventually succeed in bridging, we were prepared to rest content. As you will remember the inability of the Russian fleet to remove itself from the magnet of Port Arthur had placed the sea operations within an area which was practically limited by Port Arthur on the west and the Sir James Hall's group (Admiral Togo's rendezvous) on the east. Our receiving station was just 90 miles from Port Arthur and 125 from the Japanese advance naval base. It, therefore, behoved us to enter the arena and trust to luck and our own acumen to be present at such stirring events as this arena might unfold. My Japanese interpreter quoted a proverb to suit our case. This Japanese adage runs, "It is the wandering dog that finds the bone." We undertook the *rôle* of the wandering dog, and fortune so favoured us that we found several bones. A spell of very fair weather had set in on the Yellow Sea so we determined to hover about Port Arthur in the hope that we might witness a fleet action.

As between the dates of March 21st and April 16th, we were constantly in the thick of stirring events, and as the object of this paper is not to describe naval operations, but to place before you some of the results which we obtained through the de Forest wireless system, I will not enter into a detailed narrative of our movements, but will endeavour to narrate a few of the more striking journalistic results which we obtained by the means of wireless telegraphy. But before this I must record another mishap. Just as the mast of the receiving station was beginning to do good work, the top-gallant mast was carried away, and until this was repaired we were reduced to a 90 feet exposure. As we estimated that it would take three days to re-rig the top mast and the top-gallant mast, our first course was made in the direction of Port Arthur. At this period it was believed that, as a result of the first Japanese blockading operations, the Russian squadron was immured within Port Arthur.

The *Haimun* arrived off Port Arthur about mid-day. We were not steering directly upon the Port, but stood upon a course which would have taken us through the Liau-ti-shan channel to Taku. As we neared the Miantau group, we noticed a great belt of smoke beyond the islands. Soon we distinctly made out warships, and for the moment, believing the general report that Admiral Makaroff was immured within his base, we imagined that they were Japanese. However, we were soon near enough to count the smokestacks and with the aid of naval pocket books to recognise three battleships and two cruisers belonging to the Russian fleet. We were about 75 miles from Wei-hai-wei, and a report as to the strength, course, &c., of the Russians was immediately despatched to London. Altering our course so as to avoid coming too near to the Russian ships, we stood on under the Miantau group until dark, and then steered a course due West. About ten o'clock in the evening we were in the middle of a torpedo flotilla, which was proceeding to Port Arthur, taking with it a further number of merchantmen to be sunk in the entrance. By this the Japanese seemed to know all about us, they took no notice of the *Haimun*, and we followed them in the direction of the attack, and were able on the following morning to report the incident direct to London before Japan knew that the attempt had been made. As the attack took place in the dark, it was, of course, impossible to furnish the newspaper with details, but these we obtained within twenty-four hours by a visit to one of the Japanese bases. On this occasion we sent the really first long message that has ever been sent to a journal by means of wireless telegraphy over any considerable distance.

I should have said that in the meantime, although we had not visited our base, we had heard from Wei-hai-wei that our new mast was complete with a 165-foot

exposure of wire. We therefore determined to give the system a real trial. We commenced to send the message, which was 1,500 words in length, from 130 miles. The message was sent in four sections of 350 words each. At the end of the first section the operator on the ship listened in for a reply. All excitement, I was waiting in the chamber to see if there was any result. For about five minutes the operator remained with the telephonic receivers glued to his ears. Then I saw a light gleam in his eyes, he was getting something. At last he took off the telephone and said in his quiet, quaint American way, "Captain, we will deliver the goods, Wei-hai-wei says that it is coming in like a drum." The remaining sections were sent at once at the rate of thirty words a minute, and although we took the precaution to repeat each section, yet we might have saved ourselves the trouble, since on my return to Wei-hai-wei I compared my written message with the message that was handed in at the Eastern Cable extension, and I assure you there was not one word that had been taken wrongly.

From the moment that we realised that we were safe at 125 miles, and mind you, this is sea miles, we felt positive that the system was a complete success. If there are any who doubt it, I can only refer them to the columns of *The Times*, which had at this period exclusive information for its readers at first hand, from a theatre of operations that was beyond the reach of any other correspondent then following the fortunes of Russia or Japan in the Far East. By the instrumentality of wireless telegraphy used as an auxiliary to the cable service, *The Times* practically had the field of first hand information to itself.

The success which we had obtained, so far encouraged us that we determined to give the system a really big trial as soon as the course of the campaign should carry us a greater distance from our receiving station. It had been arranged in Tokio that my lieutenant, Mr. David Fraser, should accompany Kuroki's army in the field. The other correspondents associated with this particular force had left Japan, under the guidance of the Japanese. My instructions had also reached me from Wei-hai-wei by wireless telegraphy, telling me that it would be necessary to make the journey to Chemulpo, in order that Mr. Fraser might join the other correspondents at that port. The run to Chemulpo from Wei-hai-wei is about two hundred and fifty sea miles. Owing to weather and fog we had miscalculated and had to anchor at the entrance of the Seoul archipelago. We anchored off the island of Bundegi, which you will see from the chart is 180 sea miles from the point of Lieu-kung-tau, where our receiving station stood. We despatched a message from this island and received a reply at once. On the following day when we were returning from Chemulpo with the intention of going north to Chinampo, we sent from the vicinity of Bundegi a third long message, the aggregate of which was nearly 2,000 words. The whole of this communication was successfully received and appeared on the following morning in the columns of *The Times*.

I think that I have told you sufficient to show that we were justified in the confidence which we had placed in Dr. de Forest's assurances, but I will not close this short record of our successes without making reference to what I consider the great journalistic triumph of the war so far as the sea fighting is concerned. Mr. Fraser had missed his connection at Chemulpo and it was, therefore, necessary that we should land him with all expedition at Chinampo. By means which it is not necessary to disclose in this paper, I obtained information which showed me that I had the narrowest margin in which to visit Chinampo if I did not wish to miss important operations pending in front of Port Arthur. We bundled Mr. Fraser and his ponies and equipment on shore, and left that dangerous harbour on the night of April 12th. We had just time to make Round Island by daybreak if we went full speed. It was an occasion for burning coal; it was shovelled in, and with the help of a current we were doing fifteen knots.

As this incident was somewhat dramatic, I will read you an extract from a description written at the time :—

We anchored off Chinampo at 11 o'clock in the morning. During our passage from Chemulpo to Chinampo we had passed in the night the entrance to the base Togo was then using. What we had seen in passing had given us an idea that we had no right to be remaining in Chinampo when the place for our vessel should be off Port Arthur as soon as possible. Therefore, we lost no time in discharging *The Times* correspondent, with his baggage and his ponies. But only those who have been at Chinampo during this period of military activity can know the difficulty of landing operations. Fortunately, we were given some assistance by the authorities, and by 3 o'clock the last of the animals was off the *Haimun*. Now the navigation in and out of Ping-yang Inlet is extremely difficult at all times. The channels are very intricate and shoal, and it is impossible for

a skipper without a pilot to get clear of the islands in the dark. Moreover, a very heavy tide runs. We had 55 miles to go before we could clear and only four hours of daylight. My skipper was doubtful if he would be able to take the ship out, but he said he would try if we could prevail upon the engineer to do his best. I put it to both officers that it was a case in which we had five minutes to decide whether or not we should see possibly the greatest naval encounter of the war. Both men said they would do their best. By a merciful Providence we had the tide with us, and shovelling the coal in we made a pace against time down the inlet which I am positive no merchant steamer has ever made before. With the boilers doing their best we could knock 14 knots out of the *Haimun*. With a four-knot tide with us we may safely say we steamed out of the inlet at nearly 17 knots. It began to rain, and clouds of mist made the skipper look serious, because it was a passage in which one dare not lose one's landmarks, but he set his teeth and fulfilled his promise to do his best. Just in one of the narrow channels we had a scare. Suddenly the engines stopped. I think that in the whole of my experience perhaps this was the unhappiest moment. I knew a great deal more than any one else in the ship what it meant to us to be outside the entrance that night, and here, just as I was congratulating myself that we should be able to make the open sea, the engines stopped suddenly. I dashed down to the engine-room to find the chief engineer, not with the grave face I had expected, but with a smile. "It is nothing," he said, "only if I had continued without stopping her it might have ruined the whole show. It will be all right again in five minutes, but we had got one of the bearings screwed down too tight and it was heating, and therefore I stopped her to loosen it. She's going fine. We will get out all right," and so it proved. Again the bell rang, and again the propeller revolved, and we were making our course into the fairway. In spite of the heavy bank of clouds, and in spite of the heavy mist and the rain, the captain kept her going, and just as night dropped her final curtain we were clear of the shoals. It had been touch and go, and another quarter of an hour's delay, or the tide against us, would have caused us to miss the sinking of the *Petropavlovsk*. The effort had not been in vain, for, although we ploughed through the dirtiest weather imaginable that night, at daybreak we found ourselves abreast of Togo's battleship squadron. The rest of the story has already been told in the columns of *The Times*.

Just as day was breaking, the chief officer on the *Haimun* woke me to say that the Japanese fleet was on our starboard beam. We had hit it off exactly, and keeping abreast of Togo's squadron, we witnessed the operations which cost the Russian cause a first-class battleship and Admiral Makaroff. We saw most of the operations, and when the Japanese battle squadron hoisted its fighting flags and steamed in to engage the fortress, as the flagship, the *Mikasa*, fired her first 12-inch gun, my operator despatched my brief message announcing the fact to Wei-hai-wei. That message was sent at express rate, and consequently was in *The Times* office a couple of hours later, and making allowances for the difference of time, the newspaper office knew that an engagement was taking place six hours before that engagement began. The full descriptive details of this action, which were contained in a message of nearly 2,000 words, were sent correctly from Choda Island, 145 sea miles frm the receiving station.

I think that with these instances I have quoted sufficient to show, not only the excellence of the de Forest system, but enough to convince you that imperfect as I believe the full development of wireless communication to be, yet in its present form, as handled by Dr. de Forest, it has sufficiently advanced to be reckoned as a working adjunct to journalistic communication.

You may imagine that because I have hitherto made no mention of other systems working at the same time in the Yellow Sea that we had the field to ourselves. This is not the case. At the same time that we were working the de Forest, within a radius of 200 miles we had countless stations installed, which were working no less than four different systems. The Italian Government has a connection which works from Pekin to Chifu, *viâ* Tsin-wan-tau. The Russian system was working between Chifu, Port Arthur, and various stations on the Kwantung Promontory. The Japanese were working from their bases along the coast of Korea, and connecting with their cruisers at sea; also occasionally the British vessels in Wei-hai-Wei would be in communication. The fact that none of these other systems or stations in the smallest degree interfered with our messages shows that the de Forest system in conjunction with its speed, possesses a merit which has not yet been arrived at by any other system. It was for this reason, as demonstrated when in competition with others at the yacht races in New York, that I selected the system as the best suited to journalistic enterprise. How far our spark interfered with other systems it is beyond my knowledge to speculate, but we were careful throughout our period never to interfere when either of the belligerents was working.

We found one enemy when the rainy season approached. That was the "static" caused by thunder storms; if the atmospheric disturbances were some distance away we could manage, but if the storm was anywhere near us it was impossible to communicate with accuracy. I may say that I have only record of one occasion on which this "static" prevented me from despatching my information. Some of you may remember that *The Times* wireless service suddenly ceased. It has been stated I believe that this stoppage of the very successful channel of information was due to a breakdown on the part of the electrical appliances, in other words, to a failure of the telephonic system we were employing. Although it is not my object in this paper to take you into my confidence with regard to any differences, which I as an *employé* of *The Times* may have had with either or both of the belligerents, yet I can safely make the statement that the reason why *The Times* system ceased was because the Japanese naval and military authorities recognised that the existence of a possible channel of leakage of military secrets presented a flaw in their plan of campaign. When such vital interests are at stake that a nation is prepared to gamble with its very existence, it would be foolish to permit a possible flaw, no matter the confidence they might possess in those who directed such an instrument as a despatch boat, equipped with wireless telegraphy. No doubt apprised of the very successful results which we had obtained, the Japanese brought *The Times* despatch boat within the limit of their control, and as that control was exercised with considerable severity, it was not deemed by the direction of *The Times* that the results obtained warranted a continuance of the enormous expense which the system entailed.

Personally speaking, although when the system was working so well I would have been prepared to have carried it on indefinitely, yet the suspension of the service brought considerable relief to my mind. At that time the Yellow Sea, and especially that portion of it which it was our custom to patrol, was alive with floating mines. Moreover, the Russians, no doubt irritated by their misfortunes, had threatened both myself and my operators with a violent death if we should chance to fall into their hands. Over and above this, there was always the fear that some energetic young torpedo lieutenant would mistake us in the darkness of night for an enemy, that viewing our length of main mast he would believe us to be a warship showing lights with the intention to deceive. Therefore, though I regretted that the system came to an end just at the moment when it seemed about to prove most useful, I cannot help thinking that as far as *The Times* representatives and the officers and crew of the *Haimun* were concerned, all ruled for the best.

To sum up, I maintain that *The Times* has amply demonstrated the value and possibilities of wireless telegraphy in conjunction with journalistic enterprise; in fact, I am inclined to think that it has demonstrated its uses too well, and that the success of the system has assisted in its downfall. Moreover, I am convinced that it will ultimately prove that *The Times* has been the first and last journal to use wireless telegraphy to report naval warfare. Although I am positive that in our hands the system was always put to proper uses, yet the possibilities and the dangers are so great that in future the use of all wireless communications during military and naval operations will be controlled by international law.

And now I think I have told you all that the limit of time allowed for this short paper will permit. But as I believe it is to be followed by a discussion, I shall be only too pleased to answer any questions which you may care to ask me, provided they are not too scientific, and I am competent to answer them.

[After the reading of the paper, Captain James showed a series of lantern slides from photographs taken by himself, and also reproductions of sketches supplied by him to the *Graphic*, illustrating the incidents of the war.]

DISCUSSION.

The Chairman, in opening the discussion, said the paper was absolutely the first authentic and realistic account that had ever been submitted of a practical demonstration of the uses of wireless telegraphy. It was, indeed, quite a unique performance, and, he was afraid, it was a final performance, because after the magnificent way in which the work had been done, no existing Government would be fool enough to allow another Captain James to go coolly and quietly, with expert assistants, and report to the London *Times* their tactics, strategy and performances. Therefore, if there was one criticism that he had to make upon the paper, it was that the work had been done too well. If it had been done badly there would have been a chance of the author going and repeating his performances elsewhere, but the author had done it too well already. He had, in fact, proved himself to be the wandering dog who found the bone; and the

audience was indebted to him for giving the bone to them. The author commenced his paper by saying that he knew nothing about wireless telegraphy. He (the Chairman) thought that he knew a great deal more about it than a good many electricians did. Captain James also intimated, that, like newspaper correspondents, he was not going to be very modest, but he thought the audience would agree with him that one of the distinguishing characteristics of the paper was the extreme modesty with which the author had refused to bring his own name to the front, while he had accorded praise, with a considerable amount of exuberance, perhaps, to his assistants. Especially was that so in the case of the chief electrical assistant on the *Haimun*, who had been so prominent, and whose letter in The *Times* was one of the finest specimens of real American fun and amusement he had ever read. There was a considerable amonnt of fear expressed by the author that the possible reduction in the height of the antenna at Wei-hai-Wei and on board ship might limit the distance to which communications could be sent, but at the present day electricians did not attribute quite so much value to the height of the antenna as they did to its electrical equipment. As a matter of fact, the antenna practically controlled the lengths of the waves that were sent, but unless one desired to communicate across hills or over obstructions, height did not matter so much as it was supposed in the early days. The chief merit of the de Forest system was the great speed with which the messages were sent, and the extreme accuracy. He doubted much whether, on any telegraphic circuit in Europe, 1,500 or 2,000 words could be sent without some error being committed either by the manipulator, by the receiver, or by the writer; but to send such messages across the sea under the circumstances which had been described meant great skill on the part of the operator and marvellous development in the instruments employed. The author mentioned the fact that the news of the battle off Port Arthur was received in London six hours before it occurred. That was just the little stretch in the vivid imagination of the poetic correspondent that allowed him to make a critical remark. It was quite true that when it was announced in London it appeared to have happened six hours before, and it was the peculiarity of latitude and longitude that caused the mistake. He would illustrate his remark with a little incident that occurred to himself in the days when the telegraph was quite as great a curiosity as wireless telegraphy was now. In 1856, when the continent was first connected with England by a submarine cable, he gave a lecture in Southampton. He determined that there should be no mistake, so he induced the secretary of the telegraph company to be present in London while he (Sir William) was in Southampton at the other end of a wire, which at a certain time he arranged should be put through to the continent; and having explained the difference of longitude, causing the difference of time, and making the same remark in the poetic spirit which Captain James had done, he said to the audience that he would call up the Hague, and requested one of the audience to ask a question. The question asked was "What is the weather in the Hague;" and the answer came back. Questions of a similar nature were put to Hanover, Berlin, Dresden and Vienna. A critical newspaper editor got up and said that he should like to test what the author had said about the difference of longitude, and for that purpose asked what the time was in Vienna. It was about 9 o'clock at Southampton at the time, the Vienna time being 9.40. The reply came back over the wire, "8.20," whereupon the editor said it was a lie, and that he (Sir William) was an impostor and was deceiving the audience, and thereupon got up and walked out of the room. He was very much concerned at the incident, and he asked the operator to inquire what had occurred; and his friend, the secretary, whom he had brought to see that everything was right, said that the cable had broken down, and as he did not want to disappoint Sir William, he had been representing all the different stations. The present audience was saved from a deception of that kind, most beautiful pictures having been shown illustrative of the author's paper.

Mr. Cuthbert Hall thought that the paper was most interesting as a record of journalistic enterprise. The author had stated in the paper that his purpose was not to narrate his journalistic experiences as a war correspondent, but to show the value of wireless telegraphy for journalistic purposes. He had listened with great attention to the paper, but had been unable to understand from it exactly to what part of the wireless telegraphy results he attached special significance. If it was the distance covered, the author had mentioned distances of 160 miles; but it was a matter of common notoriety that messages were daily sent by the Marconi system over distances of 1,500 miles. Such messages were sent to ships at sea, which were unable to get the messages in any other fashion; and, in addition, hundreds of press and public messages were sent over shorter distances, which were much greater than 160 miles. If the author referred to the number of words sent, it was also a matter of public notoriety that thousands of words were sent daily by the Marconi system through its various stations. If it was the character of the message sent, if there was a special interest in war news as apart from news of the birth of children or anything else that passed over the telegraph wires, of course he had nothing to say. It seemed to him a very striking example of the interest taken in wireless telegraphy that a literary and scientific society such as the Society of Arts entertained papers, not merely on the scientific developments of wireless telegraphy, but, so far as he had been able to gather, on the character of the news transmitted. If the real point of interest was the character of the news transmitted he had nothing

further to say, but he thought he must have missed the point, because that could hardly have been the intention of the author.

Major - General STERLING said that he quite sympathised with the action of the Japanese military authorities in stopping the author's war correspondence, because both the naval and military forces would be running a very desperate risk by allowing so expert an adversary to travel over the field of operations, and send messages all over the world. Captain James had used the de Forest system with great success. He believed that other systems of wireless telegraphy were used by the other interested parties in the locality; and he thought it would be of interest if the author could state whether the only thing which hampered his transmission of messages was natural electrical disturbance, or whether the transmission of messages from other sources also hampered him at any time during his very short but interesting career.

Mr. LUKE, after thanking the author for his most interesting paper, said it was a very great relief to him, as representative of the cable business of the world, to find that instead of the wireless system of telegraphy leading, as at one time it was thought it would do, to the ruin of the cable companies, it would not be an opponent of the cable companies but a very useful adjunct. So long as wireless telegraphy companies did not want to own the earth, to supersede submarine cables, and do away with the use of wires altogether, it seemed to him their particular sphere of usefulness would be in acting as feeders to submarine cables, which would add instead of detract from their present value.

Mr. LEON GASTER thought *The Times* was to be sincerely congratulated for the enterprising spirit it had shown in being willing to spend such an enormous amount of money in the practical development of wireless telegraphy. Not only had the experiment been successful, but *The Times* were particularly fortunate in their selection of the man for carrying out the work.

Mr. J. SHARPE asked whether the author was not of opinion that, if there was sufficient money behind the enterprise, newspaper correspondents would be willing to undergo all the risks of running the blockade in order to supply information for their newspapers.

Mr. ROLLO APPLEYARD asked the number of words per minute which were transmitted by the author with the de Forest system. Mr. Cuthbert Hall had stated that thousands of words were sent per day by the Marconi system, but he understood that the rate of transmission per minute was much greater in the de Forest than in any other system.

Captain JAMES, in reply, said that he had stated in the first paragraph of his paper that he did not profess to know anything about wireless telegraphy from a scientific standpoint; but from a working standpoint he knew sufficient, by judging results, for his employers to adopt his suggestions. In reply to General Sterling's question as to whether there was any interruption with the service, the only interruption which occurred on the *Haimun* caused by an electrical body more than one mile away, was an electrical disturbance in the atmosphere. Within one mile, a word or two had been mixed up by foreign sparks from other systems. They had worked successfully over distances varying from 70 to 150 miles with the Italian, the Russian, and the Japanese systems working all round them; it had made no difference to the messages at all: he had not the means of saying or judging whether it had made any difference to theirs. He selected the de Forest system, because he found it possessed two main essentials in which, for the purposes of *The Times*, it seemed superior to the other systems that he had watched. In the first place, it did not suffer from interference; and in the second place, the operators sent and received his messages at from 30 to 35 words a minute, against 10 and 12 words a minute of every other system with which he had come in contact. With regard to the question of blockade running, he thought that if a man had nerve enough to run blockades he would have nerve enough to take wireless telegraphy instruments with him, and international law only could deal with him when it caught him. He warmly appreciated, as an *employé* of *The Times*, the feeling which prompted Mr. Gaster to mention the expense and sacrifice which that paper went to in order to serve the public in the present as well as it had served it in the past.

The CHAIRMAN, in proposing a vote of thanks to Captain James for his extremely interesting paper, thought it was only right that he should repeat the great acknowledgments that were due to *The Times* for the spirit with which it had taken up, not only the subject under discussion, but all scientific advances that were made at any time. It was just the same in the early days of telegraphy and submarine cables; and when in 1892 he first established for the Post Office wireless telegraphy between the Scottish coast and the Island of Mull, *The Times* devoted a column to a description of how it was done. It was very remarkable in the present day that so little notice was taken of the fact that wireless telegraphy existed in 1892. In 1896 Mr. Marconi came to this country; he was very warmly received, and great practical demonstrations were made of his system, but his system was only another way of doing what was being done before. The great merit of the Marconi system, which the other systems did not possess, was that it enabled them to communicate with moving ships. It was a sea busi-

ness, not a land business at all, and it was an absolute act of absurdity to conceive for one moment that wireless telegraphy was going to compete with submarine cables.

The resolution of thanks was carried unanimously, and the meeting terminated.

SEA ISLAND COTTON IN THE WEST INDIES.

The last number of the *Agricultural News* (Barbados) contains the following article on the position of Sea Island cotton, the price of which has been but little affected by the enormous increase in the crop of of American cotton:—

"The American crop is colossal, and the decline in prices should prove to your planters the folly of suggesting the planting of any other cotton than Sea Island." Thus wrote Mr. C. M. Wolstenholme, the well-known Liverpool cotton broker to the Imperial Commissioner of Agriculture by the last mail.

The crop referred to is, of course, that of ordinary or Upland cotton. The latest estimates place the present crop in the United States at about 11,000,000 bales. This represents an increase of something like 2,000,000 bales over last year's crop. It is only natural that this very large visible supply, in addition to all the cotton of a similar grade that is being produced in other countries, should have caused a considerable drop in prices. With the price of Upland cotton as low as it is to-day (about 4d. per pound), its cultivation is scarcely likely to be profitable in these colonies.

The state of the market in Liverpool is indicated by the following quotation from the *Liverpool Cotton Association Weekly Circular* of November 25: "The cotton market has been quiet throughout the week, prices have been easier, and quotations generally show a decline." Again, the following week: "The cotton market has been more active, but prices continue to decline." The prices quoted on December 2 for American cotton were: middling, 4·77d.; good middling, 4·87d. They have since fallen to 4·1d. per lb. If these quotations be compared with quotations for the same time last year (6·84d. and 6·92d., respectively), it will be seen that the decline in prices has been considerable—nearly 3d. per lb.

Turning now to Sea Island cotton, we see at a glance that the market shows a different state of affairs. To quote again from the *Liverpool Cotton Association Weekly Circular*: "Sea Island descriptions have been neglected. The quotations for fancy Georgia and Florida are reduced ½d. per lb. Forwarded this week 269 bales Sea Island." And again a week later: "Sea Island descriptions are in limited demand at unchanged rates. Forwarded this week 235 bales." Similarly with Egyptian, it was reported that a limited business had been done and quotations had not undergone much change, varying according to quality from 7½d. to 11½d. A similar, but on the whole a more hopeful, position exists in the American Sea Island markets: Messrs. Frost and Co. report that at Charleston the market remains steady and unchanged with a continued demand, and the last report (dated November 25) from Messrs. W. W. Gordon and Co. states that the market "continued quiet and steady, with a good demand at full prices." The quotations, contained in Messrs. Frost's report for December 3, will be found in the *Agricultural News*, Vol. III., p. 405. The quotations the following week were unchanged except for a decline of ½c. for fine to fully fine.

It will thus be seen that while the market for ordinary Upland has been affected to a considerable extent by the largely increased supplies, the Sea Island market (and the Egyptian also to some extent) has remained steady. The reason for this will readily be seen if we look to the crop estimates of the Sea Island sorts. The present crop is estimated at from 82,000 to 84,000 bales, as against 75,683 bales for the last crop, and 105,955 bales for the year before. The increase in production, therefore, is very slight, and consequently there has been nothing, so far at all events, to cause an appreciable fall in prices.

What it is desired to impress upon cotton growers in the West Indies is the fact that the markets for Upland and Sea Island cotton are entirely distinct. A decline in prices of Upland does not necessarily cause a corresponding decline in Sea Island. There is, therefore, no need for cotton planters here to take alarm at the somewhat sensational notices that appear from time to time with regard to fluctuations in the cotton market. They have to remember that, while the price of Upland cotton may be affected by large supplies or speculation, they have in Sea Island cotton a product for which there is a special market and a limited supply. The production is not likely to be increased to such an extent as to cause prices to drop below a figure at which its cultivation is remunerative. Provided that reasonable care be taken in producing and marketing Sea Island cotton of the highest quality, there appears to be no reason to doubt but that prices during the next season will be such as to leave a good margin of profit. In the opinion of those who are acquainted with all the facts and circumstances of the case, the price of fine Sea Island cotton is not likely to drop at any time below 1s. per lb.

Even in the event of an appreciable decline in the price of Sea Island cotton, we are inclined to think that this would ultimately have a beneficial effect. At its present high price, Sea Island cotton is out of the reach of many manufacturers who would be likely to use it if the price fell. Once Sea Island cotton had found a wider use, it is unlikely that, when the price rose again as a natural consequence of this increased demand, it would be discarded for a return to the common grades.

It would appear, therefore, that from a general

SIR FREDERICK BRAMWELL, BART. D.C.L., F.R.S.

Born 1819. *Died* 1903

From the painting by Seymour Lucas, R.A., presented to the Society of Arts by Henry Graham Harris

review of the situation as existing to-day, the prospects of the growers of Sea Island cotton are as satisfactory as they can be, and no alarm need be felt at the movements that are taking place on the ordinary cotton market. They may have a temporary quieting effect upon the demand for Sea Island cotton, but the West Indies are aiming to supply an article which is practically unaffected by these movements.

ELECTRICITY FROM WATER-POWER.*

(*Concluded from p.* 186.)

Turning now to the British Isles, the only large-scale plant for the production of electricity by water-power at present in operation in this country is the well-known installation of the British Aluminium Company at Foyers. This installation, which was originally designed by the late Mr. Birch and carried out by Mr. W. Vaux Graham, has been at work ever since the year 1896, and the whole of the power is employed for electro-chemical purposes on the spot. A small percentage of the power is utilised for the production of calcium carbide, but the bulk is, and in the near future the whole of the power will be used for making aluminium. At present the gross horse-power of the plant is 7,000 horse-power, but plant for a further 2,000 horse-power is at the present moment being installed, and will be working in about a month's time.

The water is derived from the River Foyers, which has a catchment area of upwards of 100 square miles. Storage is effected by means of two lakes, which have been joined together by the raising of dams and embankments, the result being a continuous lake of about 5½ miles long by about half a mile in width. The storage thus obtained is sufficient to run the entire plant continuously day and night for about fifty days.

From the River Foyers the water is first passed through a tunnel 8½ ft. in diameter, cut through the solid rock, to the penstock chamber, from which the water is delivered by separate cast-iron pipes to the turbines, which are installed on the shore of Loch Ness, and into which the water is finally discharged, the available head of water being 350 ft.

The British Aluminium Company have obtained parliamentary powers for a further large water-power installation on Loch Leven. It is their intention to commence immediately the development of this scheme, which is capable of giving 17,000 gross horse-power. The reservoir is artificial, and will contain about 150 days' storage of the full power, the head of water at the turbines being 964 ft. It is anticipated that the whole of this power will also be taken up in the manufacture of aluminium on the spot, no distant transmission being at present, at any rate, contemplated.

Another interesting water-power scheme of considerable dimensions is at the present moment being developed in Wales by the North Wales Electric Power Company, who have obtained parliamentary powers for this purpose. Their first installation is at present being erected under the superintendence of Messrs. Harper Bros., the company's engineers, and derives its power from Lake Llydaw, on Snowdon. This lake, into which runs the water from Lake Glaslyn, is about 1-5th miles in length and about a quarter to half a mile in width. Its area is 5½ million square feet, and it derives its water from a catchment area of about 1¾ square miles, including the summit of Snowdon. Being in the track of the Atlantic depressions, this area has one of the heaviest rainfalls in Europe, amounting on the average to 180 in. per annum. In 1903 it reached the phenomenal figure of 250 in. The prevailing winds are from the sea, and the atmospheric moisture is driven up the sloping side of the mountain, and on being condensed at the summit is discharged in the form of rain or snow on the eastern side over Lakes Glaslyn and Llydaw. The fall of the year gives the wettest months, and it happens that the quantity running from the lakes in spring is averaged up by the snow melting on the sheltered eastern side.

By means of a dam about 100 ft. in length, the level of the lake is to be raised 20 ft. The water will be drawn from the lake by means of a tunnel 600 ft. in length at a point 30 ft. below the present level, or 50 ft. below the level when the dams are completed, with the result that there will be sufficient storage for meeting a 90 days' drought. The total fall utilised will be about 1,150 ft., and the total horse-power available, on the basis of a nine hours' working day, is calculated at 8,200. The first installation consists of two steel pipe lines and four 1,000-kw. sets, each consisting of a double tangential waterwheel coupled to a three-phase alternator giving 11,000 volts at 40 periods per second.

The company will develop the full horse-power of Lake Llydaw before proceeding further, but they have also acquired a further water-power at Llyn Eigiao, in the Conway Valley, where a fall of 800 ft. is obtainable, and where it is calculated there will be nearly twice as much horse-power available as there is at Llyn Llydaw.

One of the first objects of the North Wales Electric Power Company, as soon as their installation is completed, will be to supply energy for the working of certain light railways which they control in the district. It is however, in addition, intended to supply electric energy throughout a large area, comprising the whole of the counties of Carnarvon, Merioneth, and Anglesea, and also a portion of the county of Denbigh.

Three-phase currents are to be used, and the transmission lines will be of bare copper wires, ·324 in. in diameter, carried on insulators triangularly placed on wooden poles. A large proportion of the transmission lines will be carried along the track of the

* Paper read by A. A. Campbell Swinton before the British Association at Cambridge.

above-mentioned light railways. Lines are to be laid to the principal slate quarry districts of Nantlle, Llanberis, Penrhyn, and Festiniog, where a considerable demand for power exists. The distances from the power station to these places range from six to twelve miles.

The latest water-power electric scheme in the United Kingdom is that of the Scotch Water-Power Syndicate, who have by agreement obtained from Lord Breadalbane and the trustees of the Colquhoun estate of Luss important water-power concessions. These agreements have been negotiated by Mr. E. Ristori, who, it may be mentioned, was one of the original founders of the Falls of Foyers installation, while the engineering and electrical details have been worked out by Mr. William Vaux Graham and the author.

The first power that it is proposed to develop is one connected with Loch Sloy, which is situated some five miles north of Tarbet, on the side of Ben Vorlich, between Loch Long and Loch Lomond. Loch Sloy, which is situated some 757 ft. above Loch Lomond, which, in turn, is some 26 ft. above the sea-level, is fed from a catchment area of about 3,801 acres, which includes one side of Ben Vorlich, which, with its 3,092 ft., is one of the highest mountains in Scotland. The district has the very heavy rainfall of some 74 in. per annum, of which it is calculated that 60 in. will be collectable.

A dam will be constructed at the eastern end of the loch, which will raise the height of the latter by some 60 ft. This will impound some 240,000,000 cubic feet of water, capable, with a calculated net fall of 700 ft. to Loch Lomond, of maintaining some 6,000 e.h.p. on a 25 per cent. load factor for the maximum possible periods of drought, which are calculated at 100 days.

From the loch the water will be taken in the first instance along an open conduit 3,650 yards in length, which will follow the contour line round Ben Vorlich till a point is reached almost immediately above the position where the power-house will be constructed on the shore of Loch Lomond at a spot called Inveruglas. From the end of this conduit to the power-house the water will be conveyed in steel pipes, the length of the pipe line being about 600 yards and the height of fall 700 ft.

From the power-house an overhead transmission line is to be constructed in duplicate for the purpose of conveying the electric energy to the industrial areas of the Vale of Leven and the Clyde, which comprise the towns of Dumbarton, Helensburgh, Renton, and Alexandria, and includes shipbuilding yards, engineering and dye works, calico printing works, and factories of various descriptions, many of whom have already intimated their desire to be supplied. The transmission line, for which private way-leaves have been obtained throughout, will be overhead on poles, starting from the generating station at Inveruglas, and continuing across country for a distance of 22 miles to a sub-station which will be situated at Renton, about mid-way between Dumbarton and the foot of Loch Lomond, in the centre of the Vale of Leven industrial area. At this sub-station the voltage will be reduced from the 40,000 volts which it is proposed to employ for the long overhead transmission to some 6,000 to 10,000 volts, it being the intention that the distribution from the sub-station to the various works shall be underground.

The following are the efficiencies which it is calculated will be obtained:

	Full load efficiency. Per cent.
Open conduit .... Pipe line .... Turbines	75
Three-phase generators	94
Step-up transformers	97
High-tension transmission line	93
Step-down transformers	97
Underground distribution (say 6,000 volts average)	95
Total efficiency	58·6

This is on the assumption of the energy being delivered to customers at 6,000 volts. If, as is probable in most instances, it will be delivered at lower voltages, there will be a further transformation, the efficiency of which will be 95 per cent. in the case of transformation in pressure only, and 86 per cent. in the transformation of continuous current, making a total over-all efficiencies: 55·6 per cent. for three-phase current delivered, and 50·3 per cent. for continuous current delivered.

So soon as a market has been found for the total power procurable from Loch Sloy, it is intended to utilise a further water-power—for which the rights have already been obtained—at Ardlui, about two miles further up Loch Lomond. This power is also fed by a small loch with an available fall of 800 ft. the horse-power obtainable being about half that available at Loch Sloy. The Scotch Water-Power Syndicate have, in addition, obtained the rights to still further water powers on the Breadalbane estate that exist further north, and these will be utilised as soon as the demand for power justifies the capital expense. It is because of these additional powers, which will considerably extend the length of the transmission, that it is proposed from the start to employ so high a pressure as 40,000 volts.

It is estimated that the total cost of the Loch Sloy scheme, including the transmission line and the distribution to the various factories, will not exceed £200,000, which on a basis of 5,000 horse-power delivered, works out at about £40 per horse-power, everything included. Seeing that many of the existing electric generating stations worked by steam have cost almost this amount for land, buildings and generating plant, this does not appear to be an excessive figure, and it may be pointed out as an interesting fact that the 20 miles of overhead transmission line only accounts for some £24,000, or about

12 per cent. of the total expenditure. This, coupled with the fact that the calculated loss on the transmission line at full load will only amount to about 7 per cent., and the step-up and step-down losses to another 6 per cent., making 13 per cent. in all, will give some idea of the extent to which the length of the transmission line is but a comparatively unimportant factor in schemes of this description. It may be pointed out, further, that the above-mentioned line loss of 7 per cent. is upon the basis of only one of the two duplicate transmission lines being in use. When both are employed the line loss will be reduced to 3½ per cent., and the total transmission loss at full load will be only a little over 10 per cent.

The main transmission will be on the three-phase system over two sets of three copper conductors, each about three-tenths of an inch in diameter, the possibility of conveying as much as 5,000 horse-power over a distance as great as 22 miles with only 3½ per cent. loss by means of such comparatively small wires being, of course, due to the high pressure employed. Indeed, using pressure as high as 40,000 volts, when it is a matter of transmitting comparatively small amounts of power, as, for instance, the 600 horse-power or thereabouts that, under the present scheme, it is expected will be required for the town of Helensburgh, the interesting point arises that the minimum size of conductor allowable is limited, not by electrical conditions, but by considerations of mechanical strength.

On the main transmission line the conductors will be carried at a minimum height of 40 ft. from the ground, while at all crossings over roads they will be enclosed in a wire cage to meet the Board of Trade requirements for ensuring public safety.

The application of water-power in the United Kingdom can, of course, never attain the dimensions that it has already reached in America and elsewhere; still, the above brief account of what is at present being done in Scotland and in Wales shows that there are possibilities even in this old country of which till recently but few were aware.

As regards the economies of electrical generation by water-power, no general rule can, of course, be enunciated, and every case must be dealt with on its merits, according to local circumstances. This, notwithstanding it is possible to give an indication of what is generally involved, having regard more especially to the fact that with water-power, as a rule, interest on capital plays a much greater part in determining the cost than do labour or upkeep.

Avoiding, on the one hand, small powers where the costs are likely to be abnormally high, and on the other very large powers such as we do not possess in this country, it may be taken generally that interest on capital, depreciation, upkeep, and working expenses in this country will amount to about 12 per cent. on the capital expenditure.

On this basis it is easy to see that to be economically sound the capital involved must not exceed 8½ times the annual price which can be got for the whole of the energy. For instance, if 5,000 horse-power is available for sale, and £6 can be got for each horse-power on the average per annum, the capital involved must not exceed £52 per horse-power, or £260,000 in all.

THE SLEEPING SICKNESS.

The presence of sleeping sickness on the eastern shores of Lake Victoria has given the Government of the Protectorate great anxiety. At the end of 1902 the disease had spread from its original starting point, Busoga, along the east shore of the lake as far as Port Florence. At that time it was believed that the disease was of bacterial origin, the investigation of the first Sleeping Sickness Commission having led to the conclusion that it was due to a streptococcal infection. The ordinary methods of isolation were undertaken in order to prevent the spread of disease, a segregation hospital was built at a place called German Point at Kisumu, and it was arranged that all cases occurring within a radius of ten miles of the railway station should be treated there. It was noted, however, that the disease showed no great tendency to spread in or around Kisumu, although to the north-west of the town there was a violent epidemic raging. A second commission under Colonel Bruce collected evidence tending to prove that the disease is due to an infection by a trypanosome, and that this latter is transmitted by a species of tsetse fly, *Glossina palpalis*, found in many places near the lake. The report on the East Africa Protectorate just issued [Africa No. 15 (1904)], says that this discovery showed that the ordinary methods of prevention were valueless, especially as it appears likely that the period of incubation may be prolonged to two years, or more, during the whole of which the patient may serve as a focus for the spread of the disease. At the same time, continues the report, the trypanosome theory led to one hopeful conclusion in that it could be predicted with certainty that the disease would not be likely to spread except in places where the *Glossina palpalis* was found. The exact distribution of the insect, therefore, became a matter of the utmost importance. So far as is known at present it is practically confined to a narrow area in the vicinity of the lake shore, so that if *Glossina palpalis* is the only carrier of the human trypanosome there need be little anxiety in regard to the spread of the disease into the eastern part of the Protectorate.

Unfortunately there is an area near the coast line which is infested with tsetse fly. At least three species are known to exist, all belonging to the same genus, *Glossina*, and it was suggested that the close relationship which existed between these species and the *palpalis* of the lake region might enable the former to transmit the human trypanosome just as readily as the latter does. In that case, there would be great risk of the disease spread-

ing in the coast belt, provided some infected persons were introduced into it. Experiments were accordingly conducted at Nairobi to ascertain whether any or all of the *Glossinæ* in the coast belt are able to transmit the human trypanosome. "The results," says the report, "were not entirely conclusive, but evidence was produced tending to prove that one at least of the three species of fly is able to transmit the trypanosome from animal to animal. These experiments are to be verified, as if the conclusions are correct, the prospect will be a grave one as regards fly-infected areas in the East Africa Protectorate. As, however, the tsetses of these latter are also the species which carry the fly disease of cattle, it follows that these regions are not likely ever to be thickly populated by human beings."

As bearing on the investigations which are being conducted at Entebbe by the Royal Society's Commission, and as evidence in favour of the truth of the trypanosome theory, a report compiled by Dr. Wiggins is given. Dr. Wiggins was instructed to make a thorough investigation of the whole lake coast line of the East African Protectorate, and to report on the distribution of sleeping sickness, and its relation to that of *Glossina palpalis*. Dr. Wiggins finds that where there are trees or bushes near the water, there are tsetse flies, and that where there are flies there is sleeping sickness. He finds too that there is sleeping sickness inland among those tribes who go to the lake for fish at any point where tsetses are at the lake shore. Also, conversely, that where there are no trees there are no flies, and no sleeping sickness; papyrus does not shelter them. The only river which carries the fly inland is the Kuja, which is the only one that has trees at its mouth, and thick vegetation along its course.

THE AGRICULTURAL PRODUCTS OF BOLIVIA.

Rubber is undoubtedly the principal and most valuable of Bolivian products. The belts or districts where rubber is grown and sapped are divided into four classes, according to the natural commercial outlet of the product, the first being that of the Acre or National Territory of Colonias, estimated to produce about 10,000 tons of crude rubber per annum. The second belt is that formed by the basins of the rivers Madidi, Upper and Lower Beni, Orton, Maruripi, Tahuamanu, and several lesser streams, embracing such sections of Madre de Dios, Acre, and Purus, as do not find a natural outlet through Puerto Acre. The third belt comprises the rubber forests of La Paz, and the fourth and last rubber-producing zone lies in the north-eastern district of the department of Santa Cruz de la Sierra. The department of Cochabamba also has an abundant supply of rubber trees, now commencing to be developed, and promising a great future. According to the International Bureau of American Republics, the production of rubber in Bolivia rose from 647,000 lbs. in 1890, to 2,510,000 lbs. in 1896, and to 4,180,000 lbs. in 1902. Another very important product of Bolivia is coca, which is also of considerable value. It is a shrub from two to eight feet in height, according to the locality where it is cultivated. Coca is cultivated in the lower plateaus and temperate regions of the western watershed of the Andes, in the departments of La Paz and Cochabamba. The cultivation of the plant is one of the most prosperous industries of the province of Yungas. A coca plantation with proper care may last from thirty to forty years. The total production of the coca plantations in the country is estimated at 7,700,000 lbs. annually. About three-fourths of the total production come from the province of Yungas in the department of La Paz, the balance being the product of Larecaya, Inquisivi, Caupolicán, and Yuracarez in Cochabamba. Bolivian coca commands better prices than the Peruvian product, and has, it is said, a larger demand in foreign markets, while miners and Indian labourers use it in preference to any other. Cocaine is the alkaloid extracted from the coca leaves. The physiological effects of coca vary according to the mode of using the leaves, whether in an infusion or by simple mastication. In the first case a slight nervous irritation is produced accompanied by insomnia, and in the second case its action is slow, steady and invigorating, keeping up strength without the need of food. Thus the resistance of the Indian is explained who can work steadily in the fields or undertake long and exhausting journeys without any food, maintaining his strength by simply chewing the coca leaves. It is mainly through the ports of Mollendo, Arica, and Autofagasta that the bulk of the coca exports leave for foreign markets, while it is exported to Argentina *viâ* Tupiza. Bolivian coffee is considered by many as finer than the Mocha product, and at times it has commanded a very high price in foreign markets. Yungas coffee, which was once a favourite in Europe, is now only cultivated on a small scale, but it is believed that with better means of communication and transportation facilities, coffee production will increase to the extent of making this product one of the principal exports from Bolivia. Good coffee is also produced in Beni and Santa Cruz, and exported to Chile and Argentina. The cultivation of the plant is not difficult, as it is only necessary to clear the ground of the underbrush twice a year, the first crop being gathered at the end of the third year after planting. Each tree yields from two to eight pounds every crop. In Yungas the soil is so suitable for the cultivation of the plant that coffee grows almost spontaneously. Coffee dregs or residue is an excellent fertiliser, and some use it in preference to the Peruvian guano, as it contains 85 per cent. of nitrogen. Cinchona is another important product of Bolivia, not only on account of its superior quality, but also by reason of its large production. Cinchona bark is found in all the Eastern regions of the Andes, especially in the department of La Paz, Santa Cruz, Cochabamba,

and Tarija. The number of trees in cultivation at present is estimated at six millions. Formerly there was no system of cultivation, the trees being felled in order to strip them of their bark. Now the stripping is done carefully and according to scientific methods. Bolivia was for a time the principal cinchona-producing country in the world. The Challana cinchona from the department of La Paz is the highest quality of the Bolivian bark, yielding forty-eight ounces of sulphate of quinine to the hundred pounds. There are immense cinchona forests in the department of Santa Cruz as yet unexplored. The quinine plantations of Bolivia were started by German immigrants having some knowledge of chemisty and chemical products. In size and shape and the peculiar gloss of its leaves, the cinchona tree resembles the orange. Two or three times a year three or four strips of bark are cut from the trunk and thrown upon a paved yard to dry, where, as the moisture evaporates, they curl up like the cinnamon bark. Within a year or two Nature replaces the bark that has been thus stripped off, and the tree is stripped again in other places. As the tree grows older, smaller strips are taken from the stronger branches, and the mature tree will produce an annual average of about four pounds of bark. For shipment, the bark, after it has dried for a few days, is packed in raw hide bales and exported from Arica and Mollendo. Bolivian cacao is considered on a par with the finest products of the world, as it is very rich in oil and has a delicate natural aroma. The production is sufficient for the needs of local consumption and to provide for a growing export trade. The tobacco plant is very common in the departments of La Paz, Cochabamba, Santa Cruz, Tarija and Beni, where several varieties are under cultivation, known as "Havana" "black Havana," "lechuguilla" (lettuce leaf), "lengua de buey" (ox tongue), and "criollo" (native). The total production of tobacco in Bolivia is estimated at 3,300,000 lbs. per annum. The cultivation of the sugar cane and the manufacture of its products should be one of Bolivia's principal industries. The amount of sugar cane that could be grown in the department of Santa Cruz is enormous, but the primitive methods used are a drawback to the development of this industry. It is believed that the increase in the cultivation of the cane which is also grown in the departments of Potosi and Chuquisaca, and the introduction of modern methods and improved machinery, would produce sugar capable of competing in quantity, quality and price, wlth the products of any sugar-producing country. The cultivation of the grape is one of the flourishing industries in the provinces of Mizque, department of Cochabamba; Cinti, in the department of Chuquisaca, and Loayza and Cercado, in the department of La Paz. There are two kinds of grapes cultivated in the country, the *criolla* or native variety, from the old vineyards planted by the Spaniards, and the French species, imported from Peru and Argentina. The methods employed for the cultivation of the grape are primitive, except in Cinti, where modern methods have been introduced of late. There is an immense area in Bolivia which could be devoted to the cultivation of the grape and the manufacture of its product.

ALIEN IMMIGRATION.

Reference was made in a recent issue of the *Journal* to the alien immigration figures for the eleven months ended November 30, 1904. A further White Paper has now been issued by the Board of Trade bringing the figures up to the close of the year. They show that the total number of aliens that arrived from the Continent at ports in the United Kingdom during 1904 was 195,300, as compared with 207,191 in 1903. But of these 4,949 in 1904, and 3,139 in 1903, were described in the alien lists as *en route* to places out of the United Kingdom, and the number of sailors included with the aliens who arrived at ports in the United Kingdom not *en route* to places out of it was 12,850 in 1904, against 13,432 in 1903. Deducting *en route* aliens and sailors the figures for 1904 and 1903 are 177,501 and 190,620 respectively, or 13,119 fewer in 1904 than in 1903. But a foot-note to the return says that it must "not be implied that the aliens not described in the alien list as *en route* come to this country for settlement, there being in fact a large emigration of foreigners from this country, while many of the aliens arriving from Continental ports return to the Continent."

As bearing upon the effect of alien immigration upon East-end industries, it may be interesting to quote a letter written some years ago by a director of one of the largest wholesale houses, Hitchcock, Williams and Co., of St. Paul's-churchyard, in reply to an inquiry by Mr. J. A. Dyche. The letter runs:—

"In reply to your question as to the effect upon the home labour market of the work done in London by foreign Jewish tailors, it is only fair to remind you that the foreign Jewish tailors introduced new methods of manufacture and created a trade which has become a distinct gain to the country's commerce.

"We were, we believe, the first mantle manufacturers in town to employ Jewish tailors in a factory, and it is interesting to recall our reasons for doing so. In the year 1885 the demand for ladies' tailor-made jackets came into vogue, and to meet the demand from our British and colonial trade we were compelled to import large quantities of the garments from Germany. They were made of German materials in and around Berlin.

"We tried to produce these garments in our factories but without success; our own women workers were unable to manipulate the hand-irons used by the tailors, and we could not get them to do the work. As the fashion became more pronounced,

arge orders went abroad, and in 1888 £150,000 was sent to Germany in payment for these accounts.

"In 1889 we decided to introduce foreign Jewish traders, and their special methods, into a new factory we had recently built, with satisfactory results. Their work has been excellent; British material has been used instead of German, and a large part of the money sent formerly to Berlin has been distributed among British manufacturers and in wages.

"The quality of the work has improved year by year; the garments made in our factory are better than those imported previously.

"Other English firms have followed our lead, and to-day the German press admits the loss of her trade, in those goods, with England.

"Our experience shows that these foreign Jewish tailors do a class of work which our workers cannot undertake with success, and earn a high rate of pay."

The boot trade is second in importance of the Jewish interests, but unfortunately the Jewish workman does not show to equal advantage. Here the lower class of English work has suffered considerably from foreign competition.

AUSTRALIAN FRUIT PRODUCTION.*

It is doubtful whether there exists outside the Commonwealth any adequate idea of the immense fruit-growing capabilities of the various Australian States. In Europe, America, and elswhere the name of the island-continent is generally associated with gold and pastoral produce—certainly not with fruits or flowers, though the profuse luxuriance and abundance of each constitutes one of its most characteristic features. Nearly the whole of the best fruits of the Old World have become acclimatised, and with such success that during favourable seasons they are obtained in enormous quantities, frequently of exceptional size and flavour; yet, although the soil and climate of large areas in each of the States are so admirably adapted for fruit-growing, the industry remains very imperfectly developed, partly by reason of a lack of care and skill on the part of the growers, and partly by reason of deficient means of rapid transit at reasonable rates from the more distant orchards to the principal markets. In 1902 the area under orchards and gardens in Australia was 175,483 acres, as follows:—Victoria, 58,415 acres; New South Wales, 55,847 acres; South Australia, 26,865 acres; Tasmania, 14,568 acres; Queensland, 13,023 acres; Western Australia, 6,765 acres. According to the New South Wales Government Statistician, the average annual value of the Australian fruit crop during the last five years was as follows:—Victoria, £696,000; New South Wales, £457,000; South Australia, £358,000; Queensland, £179,000; Tasmania, £177,000; Western Australia, £81,000; total, £1,948,000. The values of the oversea exports of Australian fruit in 1903 were:—Dried and bottled fruits, £22,222; fruit pulp, £37,240; and fresh fruits, £217,912; total, £277,374. According to Mr. McLean, the Victorian Statist, the fruit produce of Victoria, during the year 1903-4 comprised:—654,965 cwt. grapes, 251,373 cwt. apples, 56,495 cwt. pears, 29,113 cwt. quinces, 108,736 cwt. plums, 64,215 cwt. cherries, 88,414 cwt. peaches, 114,305 cwt. apricots, 9,635 cwt. oranges, 20,842 cwt. lemons, 8,959 cwt. figs, 22,377 cwt. raspberries, 3,122 cwt. strawberries, 14,199 cwt. gooseberries, 2,312 cwt. currants (black, white, and red), and 4,297 cwt. miscellaneous; also 113,791 lb. almonds, 13,276 lb. walnuts, 2,223 lb. filberts, and 6,677 lb. of chestnuts. This does not include fruits grown for private use. In Queensland the fruit produce of 1903 included 2,362,520 lb. of grapes, 1,112,578 dozen bananas, 340,832 dozen pineapples, and 1,150,514 dozen oranges. In New South Wales, where the statistics of fruit produce are extremely meagre, the figures include: grapes, 378,832 cwt., and oranges and lemons, 6,534,620 dozen. In South Australia the grape production in 1902-3 was 26,175,472 lb. The total grape production of the Commonwealth in 1902-3 was 57,538,200 lb., from which, exclusive of the portion retained for table use, 4,785,440 gallons of wine and considerable quantities of brandy were obtained. Grapes and citrous fruits did not thrive in Tasmania, their places being taken by strawberries, raspberries, pears and apples, which are exceedingly plentiful and of rich flavour. In Victoria and South Australia considerable attention is given to the fruit-drying industry. In the former State the output of raisins in 1903-4 was 5,986,064 lb. and of currants 838,880 lb. The dried fruits also included 25,137 lb., apples, 58,293 lb. prunes, 114,096 lb. peaches, 184,960 lb. apricots, and 17,599 lb. figs. The weights are after drying. In the Victoria orchards, as in those of the other States, considerable quantities of melons, rhubarb, and tomatoes were produced, the figures in 1903-4 being: melons, 23,109 cwt.; rhubarb, 49,259 cwt.; and tomatoes, 28,990 cwt. If the produce of private orchards were included, the totals would become largely increased. Western Australia is likely to become one of the great fruit-growing countries of the future, the soil and climate in many places being admirably adapted for the production of grapes, citrous fruits, apples, pears, plums, peaches, apricots, nectarines, &c. Suitable land for fruit cultivation is readily obtained, and there is a good local demand for all the choicer kinds at remunerative prices. The export trade is yet in its infancy, but considering that in Australia the seasons are reversed, and that all the leading British and American summer fruits, such as cherries and strawberries, are most plentiful from November to February, there should be a large oversea market for them. The most successful growers are orchardists who have had some previous experience of the industry in other countries, and are familiar with the proper conditions of cultivation. To such men the Commonwealth is a country of great possibilities.

* Communicated by Mr. John Plummer, Sydney.

TEA: CONSUMPTION AND TAXATION.

It may be some slight consolation to one here and there of the many who are complaining of an eightpenny duty on tea to be reminded that their forbears who drank tea were much more heavily taxed. It was not until the Revolution that any duty was laid upon tea other than that levied on the infusion as sold in the coffee houses, but in the first year of William and Mary a duty of 5s. per lb., and 5 per cent. on the value, was imposed. For many years very little was imported. It was not until 1677 that the East India Company took any steps for the importation of tea, and at the end of the century the imports did not exceed 20,000 lbs. a year. This importation was practically a monopoly of the company, who, if the tea was imported in their ships from the place of growth, paid less than half the duty leviable on all other importations of tea. Later on (1721) the importation of tea from Europe was prohibited, thus granting the East India Company an actual monopoly, a system which gave rise to an unsatisfactory state of affairs, and was abolished in 1833. In that year the average price of Congou was 2s. 6½d. per lb, and of Hysonan 4s. 2d. With the abolition of the monopoly the consumption grew apace. In 1840 it was 1·22 lb. per head; fifty years later it had risen to 5 lb. It is now nearly 7 lb. And not less remarkable is the shifting of the source of supply from China to the British East Indies. Thirty years ago (1875), of the tea consumed in the United Kingdom 84 per cent. came from China, and 16 per cent. from India. Ceylon did not begin to export until 1883, when it sent us 1,000,000 lbs., whilst the percentage that came from India had risen to 33 per cent. In 1896 China only supplied us with 11 per cent. of our consumption, the percentage of Indian had increased to 54 per cent., and of Ceylon to 35 per cent. In 1902 the total value of the tea imported into the United Kingdom was £8,787,000, of which only £457,000 worth came from China, the British East Indies accounting for £7,937,000.

Levied as it is the present duty on tea falls very unequally upon the rich and poor buyers, assuming the rich purchaser to buy the better teas. The present price of ordinary Indian and Ceylon tea averages about 7d. a lb. It is burdened with a duty of 8d. a lb. The lowest-priced leaf tea to be obtained on the market is 4¾d.-5d. a lb. It is crushed with a duty of 8d. a lb. Whilst the 8d. duty on the best tea represents not more than 20 per cent. upon value, the duty on the cheapest tea is over 160 per cent. The cheapest leaf tea sold to the public by the retailer is 1s. 1½d. per lb. How can it be sold at that price? Take the lowest-priced leaf at 4¾d.-5d. a lb., add a 1½d. a pound for handling, and the duty of 8d., and there is 1s. 2½d. The conclusion is irresistible, that the tea sold at this price is mixed largely with dust, and made up with re-dried leaf.

Mr. Herbert Compton has given an interesting analysis of the financial aspect of the tea question as it affects the East Indies and the Mother Country. With the average market value of Indian and Ceylon teas at 6½d. per lb., the value of the total Indian and Ceylon tea crop of (approximately) 240,000,000 lb. duty paid, is £14,500,000, landed in this country. This sum he dissects and apportions as follows:—To the British Government for duty, £8,000,000. To Indian Government railways, British steamship companies, and London wharfingers for carriage from Indian tea-gardens and delivery into bonded warehouses, £1,500,000. To British manufactures of tea lead, garden stores, agricultural implements, and tea actory machinery, &c., estimated at about ¾d. per pound of tea turned out, £750,000. To the tea planters for growing and manufacturing the crop (including profit if any) on over £30,000,000 British capital invested £4,250,000. The return to the tea planter upon his capital has fallen to about 3 per cent.

Reference was made above to the increase in the consumption of tea. The returns indicate the extent to which the duty affects the increase. In 1885, with the duty at 4d., there was an increase of 4·25 per cent. In 1886 the duty was raised to 6d., followed by a decrease of 1·92 per cent. The average increase for the three years following was 1 per cent. For the ten years 1890-99 the duty was only 4d., and the average increase in consumption was 2½ per cent. In 1900 there was a 6d. duty again, and the increase for the year was ·74 per cent., probably the figures for the past year, with the eightpenny duty, will show a decrease. If not the only explanation is that the public have consumed a much larger quantity than heretofore of a very inferior tea mixture.

COAL EXPORTS.

During the fiscal year 1903-4 the exports of coal, &c., were just upon 47,000,000 tons, and the bunker coal only a little short of 17,000,000 tons. This is the largest output upon record, and it is reasonable to assume from it that the coal tax has not materially affected the volume of our coal exports. The continuous upward movement of these exports is very remarkable. If the last fifty years are taken, it will be found that four out of every five show an increase on the preceding year, and every quinquennial average of the half century shows an increase on its predecessor. With the exception of 1877 the decline was never over 5 per cent., and in that year it was very little more—14,881,000 tons as against 15,690,000 tons in 1876. Often in the face of circumstances that must have exercised a very prejudicial effect—as for example last year, which was a very bad one from the shipping point of view—the growth has gone on. Financial panics, famine prices, commercial depression, all have had to be reckoned with, but they have been hardly traceable in the total figures. Labour disputes seem to have been more accountable for the heavier decreases, than anything else. In 1877, when

the decrease amounted to a little over 5 per cent., there were numerous labour troubles, which, coupled with the falling off in the Baltic demand, explains the shrinkage of the year. The effect of labour troubles are clearly traceable in the particular groups of shipping ports more immediately concerned, but the enormous expansion in the use of steam, more especially for navigation purposes, has usually more than made up in the grand total of exports for the deficiency of particular districts.

With an export last year of close upon 64,000,000 tons, the opinion expressed by the Coal Commission of 1866 reads strangely. In this report, issued in 1871, the Commissioners stated that "as regards the future exportation of coal, although a very large increase has taken place within the period embraced by the preceding table (1855-1869), yet there is reason to doubt whether much further increase will take place in this direction." The export given in the table for 1869 was 10,245,000 tons, and if we add 2,100,000 for bunkers, the total is 12,345,000, as against the 64,000,000 of last year! And yet the majority of the Commissioners were men of acknowledged ability and great scientific attainments.

The reduction in freights consequent upon the substitution of steam for sail has had much to do with the growth of our coal exports. Mr. D. A. Thomas, M.P., gives some very striking figures under this head. He shows that outward coal freights, in what may be called ordinary times, are now not half what they were thirty years ago. 1901 represented a normal condition of things, and if the freights ruling in that year are compared with those of 1872, it will be found that the average coal freight from Cardiff to eighteen principal ports in the French and Mediterranean group was 14s. 1d. in 1872 and 6s. 4d. in 1901, a fall of over 55 per cent., while the general average of the freights to forty ports in different parts of the world fell from 20s. 2d. in 1872 to 9s. 10d. in 1901. Broadly, normal coal freights are less than half what they were a generation ago. In 1902 the average freight (5s. 4d.) from Cardiff to Port Said (3,072 miles) was below the cost of carrying coal by rail from Sonth Wales (say the centre of the Rhondda Valley) to London (170 miles), Liverpool (175 miles), or Southampton (128 miles).

MOLASCUIT.

Mr. George Hughes (Consulting Chemist to the Agricultural Society of Barbados) lately gave an address at Lewes on "The Cultivation of the Sugar Cane, and the Processes of Manufacturing Sugar, with especial reference to the utilisation of its Bye-products," before the East Sussex Farmers Club.

The crushed cane leaving the mills is called megass, and this hitherto has always been used as the fuel to boil the juice into sugar and molasses. This procedure is something akin to burning straw if it were necessary to use much fuel to produce marketable corn. Doubtless it is an excellent use for the rind, but the interior of the megass from which the juice has been expressed Mr. Hughes found on analysis to be 75 per cent. digestible, and, therefore, suitable for feeding purposes. It has now been demonstrated that it is quite easy to separate what might be described as this honeycomb by disintegration and screening.

Showiug a sample of screened megass meal, he said, the absorbing properties of this are remarkable, but this fact is not surprising, seeing that the cells of which it is formed originally held 90 per cent of juice.

The crop of molasses obtained for each ton of sugar is equal to from 5 to 7 cwt., according to the condition of the juice, which is much affected by the seasons. In many places this bye-product is taken to distilleries and converted, after fermentation, into rum. Of late years the price of this commodity has been much depressed, and, if not an actual loss to manufacturers, it has barely covered the expense of production. Molasses would long ago have been more largely used for cattle feeding but for the expensive packages necessary for shipment, and the difficulty of handling them has been a deterrent of its coming into general use for this purpose. You cannot make a meal of molasses pure and simple, but by taking 20 per cent. of the dry megass meal, 80 per cent. of molasses is easily absorbed and so completely that the product is not even sticky if the megass meal be fairly dry. It can then be dessicated and the 25 to 30 per cent. of water in molasses more or less replaced by this dry, digestible megass matter.

Everyone knows that sugar pure and simple cannot be taken in any quantity at a time, because, all being soluble at once, it would soon nauseate and upset the digestion, but Mr. Hughes said he could show that molascuit slowly gives up its saccharine matter, in a simple experiment by mixing water and decanting, and water poured upon the sediment still yields sweetening matter. It is therefore practically a natural food made entirely from the one product, the sugar cane almost in its natural state, only the cells charged with this concentrated molasses instead of original juice.

It is not reasonable to look upon this new commodity as a complete food, but it will be found a valuable addition to all other feeds in proportion to the nitrogen matter they contain. It may in time reduce the necessity of growing mangolds. The practical farmer will chaff his hay and straw and mix molascuit with this chop, and not forgetting to add the water which would have been found in his roots to the extent of 90 per cent. One ton of molascuit can equal eight tons to ten tons of mangolds, the feeding of which, according to analysis, is chiefly dependent upon sugar. I make this statement, not as a proved fact, but a point upon which experiments can be made, and certainly one that invites discussion.

The British farmer often pays a fancy price for compound feeds, and many of the feeds have established their reputation, on the fact, although not

generally known, that they contain molasses or sugar in their composition. Here you have molasses in a dry condition, admirably suited for mixing with your other feeds, be it hay, straw, or cotton and linseed cakes, &c., and molascuit should be sold at a price which means economy to the farmer.

Mr. Hughes further quoted figures showing the increase in the use of molascuit. In 1903 only 1,762 tons were exported; last year, up to November 17th, 5,445 tons had been sent over from British Guiana alone.

CHINESE TOBACCO.

The cultivation and manufacture of tobacco is one of the great industries of Ssuch'nan. The plant is grown extensively throughout the province for local consumption, but the chief centre of production and export is the Plain of Ch'êngtu, notably the districts of Chin-t'ang Hsien, P'i Hsien and Shih-fang Hsien. Many years ago, the excellence of the Ssuch'nan leaf was discovered, and trial shipments were made to Europe, and if better methods of production were introduced into the growing districts, it is expected that the industry would have a great future, especially in foreign markets. The seed is sown in a seed bed in October, and the bed is then watered with liquid manure, and covered with rice straw; when the seedlings have attained the height of half an inch, the straw is removed, and screens made of rape stalks are set up to protect them from frost, snow and cold, to which they are exceedingly sensitive. If the weather is dry during the winter months, the seedlings are watered several times. Consul-General Hosie says that in March they are sufficiently advanced to be transplanted into rows, eighteen inches apart, and a like distance between the plants. A considerable interval is left between each set of two rows, and at the end of April the plants are banked up, each two rows forming a bed of fine black loam about two and a-half feet wide, with the plants near the edges, while the intervals between the beds are converted into trenches two feet deep by two and a-half feet wide at the top, and narrowing to about one foot at the bottom. These trenches are the irrigation channels, and the Plain of Ch'êngtu being one network of streams and canals diverted from the Min River, it is a very simple matter to allow the water access to any particular field as required. After banking up has taken place, the trenches are filled with water every morning to within an inch or two of the surface of the beds, and as the plants are close to the edges, their roots are easily irrigated. Every four or five days, however, liquid manure is applied to the plants instead of water. By the middle of May the plants have grown to the height of a foot or more, and the tops are then snipped off by hand to prevent flowering and to divert the sap to the leaves which have already attained large dimensions. Irrigation now practically ceases unless the weather is exceptionally dry and the crop is harvested from the middle to the end of June. Each leaf with its stalk, is carefully removed by hand and spread between two openwork bamboo screens capable of holding twelve or thirteen leaves without overlapping. The screens are placed in the sun for four or five days, when they are opened and the leaves, which are now of a brown colour, are removed. The contents of about a hundred of these screens are then placed together between two larger but similar screens, and firmly bound with rope for four or five days, when the bundle is opened and each leaf removed separately by hand and assorted into bundles of about three and a half catties (about five pounds avoirdupois) in weight, each of which is tightly bound with a band of rice straw encircling the flat bundle across the width. Each bundle contains about one hundred and thirty leaves. In this form, called "Ta yen," or large tobacco, the bundles are packed, circulated throughout the provinces, and find their way down the Yangtsze beyond the borders of Ssuch'uan. The smaller leaves, called "Er yen," or second tobacco, having undergone the same processes as the preceding, are manufactured into "Shui yen," or water tobacco, for smoking in the Chinese water pipes. The stalks and larger veins having been removed by hand from the leaves, the latter are spread in layers in a wooden box, and rape oil is sprinkled between each layer. When full, a lid is placed on the top and weighted with stones to press out the superfluous oil. After two days stones and lid are removed, and the contents of the box are cut up into slices about two inches wide. These slices are placed in a press for from four to six days, till they are sufficiently hard to be planed into thin tobacco called "Tiao Ssu." An inferior quality of water tobacco is made by adding with the rape oil a certain quantity of "T'u-hung," a red-coloured earth, to the leaf when placed in the box. This quality is called "Shuang Lan." The stalks and veins of the leaves are dried, ground up, and added to the water tobacco. The tobacco most generally manufactured and consumed in Ssuch'uan, as well as exported, is called "So yen," or cord tobacco. The leaves are harvested, and each leaf is cut close to the stem of the plant. Two inches of the end of each stalk are bent over to form a hook, and by this means the leaves are hung on cord or rope stretched under cover in sheds or under the eaves of houses. In the centres of tobacco cultivation special sheds are erected for the purpose. The leaves are in this way exposed to the air for twenty days. At the end of that period they have changed from green to brown and have shrivelled up laterally. On the twenty-first day they are hung outside the shed for one night and exposed to the dew. Next morning they are taken in and rolled up tightly with the cord in bundles of about 26 pounds in weight. After two days the bundles are opened, suspended under cover for two days, and again exposed for one night in the open. This takes place a third time, when the leaves are removed from the

cord and assorted according to size. They are now ready for market. The district of P'i Hsien is credited with only 2,000 piculs (about 120 tons) of cord tobacco, its principal energy being devoted to the production of "Ta Yen," "Erh Yen," and water tobacco, which is placed at 120,000 piculs (about 7,200 tons). Chin-t'ang and Shih-fang districts, on the other hand, devote themselves for the most part to the manufacture of "So Yen." The consensus of native opinion is that the best flavoured leaf in the province of Ssuch'uan is grown in the district of Chin-t'ang, and is closely followed by P'i Hsien and Shih-fang Hsien. The best "T'u-hung" or earth red, used for mixing with the inferior water tobacco, comes from Chiang-an Hsien on the Yangtsye, between Lu-Chou and Hsü-chou Fu.

NAVAL EXPENDITURE AND MERCANTILE MARINE.

The Parliamentary paper on naval expenditure and mercantile marine just issued is useful although its title does not accord with its contents. It claims to be a return showing aggregate naval expenditure on sea-going force "for the year 1903," but the figures for the United Kingdom are only brought down to the 31st March, 1903, whereas those for Germany and Japan are down to the 31st March, 1904, and for the United States to the 30th June, 1904. Again, in comparing aggregate naval expenditure and aggregate revenue the aggregate revenue of Russia is put at £218,676,000, which must include items not shown in our Budget of £141,545,579. With a merchant shipping of 10,268,604 tons to protect the aggregate naval expenditure of the United Kingdom on her sea-going force was £35,525,732. Russia with an aggregate tonnage of mercantile marine of only 678,594 spent £12,349,567 upon her navy, and France with a merchant marine of 1,217.614 tons spent upon her fleet £12,538,861. If we spent as much in proportion to our merchant fleet as, say, Russia, it would cost us over £150,000,000 a year. But of course fleets are maintained for purposes besides the protection of merchant shipping. For example, that of Russia in the China seas, and of France in the same waters. Perhaps the most remarkable figures in the returns are those which relate to Japan. The aggregate naval expenditure on sea-going force of Japan for the year ended 31st March, 1904—a year of preparation for war and war itself—was only £2,354,904. Hardly less remarkable in a different way are the figures relating to our self-governing colonies. They have an aggregate revenue of £69,491,029, and between them they contributed £361,959 towards the up-keep of the Imperial Navy. The Dominion, whose aggregate revenue (£13,574,286) was more than half that of Japan (£25,518,000), and exceeded that of Portugal (£11,877,000) by nearly two millions, and was practically the same as that of the Netherlands (£13,833,000) paid nothing. Nor are the discrepancies between the Colonies themselves less striking. The Dominion of Canada has 683,147 tons of merchant shipping and contributes nothing towards the navy that protects it; Natal has only 2,241 tons of shipping yet contributes £25,625. The Commonwealth contributes £259,869 for the protection afforded by the Imperial Navy to its 357,509 tons of shipping; the Cape of Good Hope which has only 3,681 tons contributes £62,500.

LONDON BUILDING AND THE COUNTY COUNCIL.

The London Building Acts Amendment Bill which the London County Council will invite Parliament to consider and adopt in the coming session, is a formidable measure of 184 clauses, not to speak of the schedules. Its object, as its title implies, is to amend the Acts relating to buildings in London, and to confer various powers on the Council. According to the Preamble, the existing powers possessed by the Council "are insufficient to secure the construction and maintenance of streets and buildings in the Administrative County of London in a satisfactory manner, the provision and maintenance of proper means of escape in case of fire from such buildings, and the reduction of the risk of fire in the case of such buildings." Some of the most important provisions of the Bill are those that relate to "means of escape in case of fire, and provisions for reducing risk of fire in buildings." If Parliament adopts these provisions in anything like their present shape the risk of serious conflagration in London ought to be materially lessened. Clause 54 stiffens Section 47 (height of buildings) of the Act of 1894, and provides that consent to the erection of certain high buildings shall not be given "unless both the superintending architect and the chief officer of the Fire Brigade certify that proper arrangements can be made and maintained in connection with such building or lessening the danger from fire." No person without the consent of the Council may erect or raise "any dwelling-house to a height greater than the width of any public street or way adjoining the same, and used for the purposes of foot traffic only, whether formed or laid out before or after the commencement of this Act, unless such dwelling-house shall be so erected or raised that no external wall thereof shall be in any direction at a less distance than twenty feet from the centre of the roadway." No stairs may be constructed with a rise of more than seven inches and a half, or a tread of less than eight and a half inches, clear of nosings, except in the case of windows.

Clause 81 provides that "In every church or chapel, meeting-house, public hall, public lecture room, public exhibition room, and public place of assembly, whether constructed before or after the commencement of this Act, all exit doors and barriers shall be made to open outwards, and if fastened during the

time the building is in use, be fastened during such time by automatic bolts only so as to open outwards by pressure from inside." That is a most valuable provision, although it will surprise many to learn that the County Council have still to ask the sanction of Parliament for powers to enforce the making of doors to open outwards. Clause 87 again has much to commend it. It runs, "All constructed iron work in any new building shall, with the object of protecting the same from the effects of fire, be encased to the satisfaction of the district surveyor, the concrete, brick work, terra-cotta, or match lathing and plaster, or cement not less than two inches in thickness." Again, no materials may be used in the construction or alteration of any building if they have been disapproved by the district surveyor on the ground that they are of bad quality.

Part VIII. deals with the means of escape in case of fire, and seeks to reduce risk of fire in buildings. All "high buildings," that is, buildings with the level of the upper surface of the floor of any storey a greater height than fifty feet above the level of the footway, must have the certificate of the Council that its requirements have been complied with before it may be occupied or let for occupation. Clause 105, which deals with access to roofs, is very important. It provides that every building, having more than one storey above the ground storey, or exceeding 25 feet in height, shall be provided with either a dormer-window or a door ~~opening on to~~ the roof, with proper access to it; or a trap-door covered with copper or zinc, and hung on hinges so as to admit of the same opening to the fullest extent, and furnished with a counter-weight so as to ensure that it shall open automatically when unfastened, and also with a fixed or hinged step-ladder leading to the roof; or other proper means of access to the roof, and with a sufficient parapet or guard-rail where necessary, to prevent persons slipping off the roof. Any dormer-window or trap-door provided under the sub-section shall only be fastened in such a manner as to ensure access to the roof being always readily available from the inside of the building. It will be the duty of the district surveyor, on finding that there has been failure to conform to these requirements, to forthwith serve on the owner notice to carry out all such works as may be necessary to conform to the Act.

Space does not allow reference to any other clauses dealing with the fire danger, or to refer to other matters such as lines of building frontage, prohibitions of irregular structure or forecourts, communication bodies, the height of buildings, the numbering or naming of streets, light and ventilation of habitable basements, &c. Enough has been said to shew that this is a very wide-reading Bill. No doubt it will be largely amended in details in its course through Parliament, but its main provisions are not likely to be materially altered. Unfortunately the coming session, with its dissolution possibilities, may be too short and stormy to enable the necessary time to be given to the consideration of this very important measure.

BOHEMIAN INDUSTRIAL EXHIBITION OF 1906.

For some considerable time past, especially in German manufacturing circles, plans have been maturing for the holding of an industrial Exhibition of more than ordinary magnitude in Reichenberg in 1906, and, according to the United States representative at that place, complete success has been achieved. The guarantee fund amounts to nearly £120,000, to which every City in German Bohemia has contributed. This fund is only a guarantee against financial loss, and therefore does not represent the outlay on buildings, grounds, and administration, for in that part of Europe these exhibitions are conducted upon a purely business basis, and are expected at least to meet expenses. A large number of workmen have been engaged in preparing the grounds, and it is proposed to complete the buildings, so that everything, including installation, shall be ready on the opening day in May, 1906. The Exhibition is to remain open until October. As no other Exhibition, either in Austria or Germany, is thus far in contemplation for 1906, it is practically certain that Reichenberg will then monopolise the attention of the exhibitors and public in German Europe. All branches of Bohemian industry—manufacturing, forestry, arts, &c—will be represented in collective exhibits. As manufacturing in Bohemia, though carried on to a vast extent, is scattered in small villages over a wide territory, it will afford a good opportunity for the inspection of Bohemian products, especially in cotton, linen, wool, glass, precious and imitation stones, imitation jewellery, and the peculiar manufactures of the Gablonz district. To an inquiry as to whether foreign exhibits were desired, or would be permitted, answer was made that auxiliary machines and materials, such as are not manufactured in Bohemia, would be admissible; in other words, only non-competitive articles. Applications for space, which should be accompanied by full particulars of the proposed exhibit, are to be addressed, An die Austellungsleitung gräfl. Schloss, Reichenberg, Böhmen.

CORRESPONDENCE.

RURAL HOUSING AND BUILDING BYE-LAWS.

It may be of interest to supplement the information contained in the note on "Building Bye-laws," in the last issue of the *Journal*. In the twenty years, 1881 to 1901, there were created 244 urban districts. That many of these are not in reality towns is shown by the Registrar-General, who observes, in his report, "A considerable number of urban districts, though technically urban, are distinctly rural in character, being in many cases small towns in the midst of agricultural

areas, on which they are dependent for their maintenance as business centres. At the recent census (1901) there were as many as 215 urban districts with populations below 3,000; 211 with populations between 3,000 and 5,000; and 260 with populations between 5,000 and 10,000. In other words, nearly two-thirds (686 out of a total of 1,112) of the urban districts have less than 10,000 inhabitants." The density of populations may be gathered from the fact that in the 260 districts with populations between 5,000 and 10,000, there were on an average less than 1,500 persons to a square mile, as compared with 18,000 per square mile in towns of over 250,000 persons, and about 39,000 in the County of London.

There is unanimity of opinion that the existing state of rural housing is attributable to some extent to rural authorities having applied, with the consent of the Local Government Board, urban regulations to rural areas. But sufficient publicity has not been given to the fact that had rural authorities followed more closely the intentions of the Public Health Act, 1875, the present state of affairs might not have arisen.

For however weak the Act of 1875 may be in some respects, it clearly distinguishes between the public health requirements of town and country. A marked distinction is drawn, for example, between the duties delegated to officials in urban and rural areas. Whilst it is compulsory upon urban authorities to appoint a medical officer of health, surveyor, and inspector of nuisances (Sect. 189), the officers which every rural authority *shall* appoint are the medical officer or officers of health, and the inspector or inspectors of nuisances (Sect. 190).

It is particularly noticeable that no provision is made, in the sections quoted, for the appointment of surveyors in rural areas, and that this omission was intentional is shown by the term "surveyor" as applied to rural areas being merely included among the definitions to the Act (Sect. 4), thus:—"'Surveyor' includes any person appointed by a rural authority to perform any of the duties of a surveyor under this Act."

Hence the Act of 1875 implied that in rural districts surveyors' duties should be of so light a nature as not to necessitate the appointment of a special officer. The fact, too, that the section referring to the appointment of rural officers is worded to include the plural as well as the singular in the cases both of medical officers and inspectors of nuisances, is a further indication that the Act of 1875 anticipated the sanitary work in those districts would be covered by the duties devolving upon the two grades of officers mentioned, and provision was accordingly made for increasing their number if necessary.

These intentions of the Legislature have been frusfrated by the adoption of urban building bye-laws, for the majority of rural councils have thus created the work of urban surveyors over the whole of their districts, and have in some instances considerably extended the work by adopting other Acts of an urban character. This has had the effect in many districts of bringing existing (or old), as well as new buildings, under town restrictions.

When it is remembered that in addition to the powers thereby placed in the hands of surveyors, the medical officers of health and sanitary inspectors have also far-reaching powers over drainage, water-supply, unhealthy dwellings, and other sanitary work in close relation to the duties of surveyors, it is not surprising that in rural districts the over-lapping of work has become vexatious to the public.

In a review of the rural housing question which appeared in a former issue of the *Journal*,* it was shown that some urban powers tend to prejudicially affect sanitary administration in rural areas, and in the interest of sanitation, if for no other reason, rural councils should confine the adoption of urban powers to such parts of their districts as have actually become urban in character. There is perhaps no more mistaken notion in the mind of the general public than that urban powers are bound to lead to sanitary improvements in rural parts. As a matter of fact, urban powers are often as unsuitable for country areas as rural regulations would be if applied to crowded cities.

T. BRICE PHILLIPS.

GENERAL NOTES.

STERILIZING WATER.—An apparatus for sterilizing water, designed by Mr. P. G. Griffith, is described in *The Times*. The apparatus is based on the fact, which he claims to have proved by his experiments, that in order to kill the organisms of water-borne diseases, such as enteric, cholera, and dysentery, it is unnecessary to have recourse to a temperature so high as boiling point, but that they are immediately destroyed by heating the water to any temperature above 73° C. (164° Fahr.). He takes advantage of this circumstance to economise heat by not using temperatures above 80° C. (176° Fahr.) for the operation of sterilizing, and he effects a further economy by employing an interchange cooling arrangement by which the heat of the water which has passed through the boiler is transferred to that which is on its way to be sterilized. In this way the ingoing water is made to enter the boiler at a considerable temperature, the consumption of fuel being thus reduced, while a corresponding cooling is effected in the sterilized water, which therefore becomes available for drinking purposes much sooner than would be the case if it issued almost at boiling point. An important feature is a device which automatically cuts off the supply of water to the cooler whenever the temperature of the water in the boiler falls to 73° C. (164° Fahr.). This consists of a series of metal capsules, containing liquids which boil at different

* "The Rural Housing Question." *Journal of the Society of Arts*, vol. lii., March 25, 1904.

points, and so arranged that the water-valve remains closed by a spring until it is forced open by their expansion. A similar arrangement, acting in the reverse sense, extinguishes the lamp should the temperature of the boiler rise unduly owing to failure of the water supply. Heat is obtained from a petroleum vapour lamp. The experimental apparatus on view at 396, Euston-road, is capable of yielding about 60 gallons of water an hour, with a consumption of something over 30 oz. of oil, or about half an ounce of oil to a gallon of water, and the delivery of sterilized water begins four or five minutes after the lamp is lighted. The weight is about 120 lb., but it could probably be reduced. The machine was primarily designed for use with armies in the field, and the water, strained through cloth or charcoal to remove coarser suspended matter, may either be supplied from a water cart through a flexible pipe or pumped up from any convenient stream or pond.

INDIAN IMMIGRANTS IN TRINIDAD.—The Annual Colonial Report for Trinidad and Tobago for 1903-4 states:—That during the period under review, four immigrant ships arrived from British India, bringing with them 2,458 persons, of whom 676 were women. One return ship to Calcutta conveyed 721 persons, and money to the value of £9.320 besides gold ornaments. These figures, while bearing testimony to the comparative wealth which the thrifty East Indian imported under indenture can attain in this colony, indicate also that Trinidad is annually losing, by return to their native land, an appreciable number of men and women who have proved themselves to be desirable citizens.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock:—

JANUARY 25.—"London Electric Railways." By the HON. ROBERT P. PORTER.

FEBRUARY 1.—"The Navigation of the Nile." By SIR WILLIAM H. PREECE, K.C.B., F.R.S. SIR ROBERT HANBURY BROWN, K.C.M.G., will preside.

FEBRUARY 8.—"Time Development in Photography, and Modern Mechanical Methods of carrying it out." By R. CHILD BAYLEY. GEORGE DAVISON will preside.

FEBRUARY 15—

FEBRUARY 22.—"Some Misconceptions of Musical Pitch." By JOHN E. BORLAND. (*a*) *Visual*—due to conventional but inaccurate notation; (*b*) *Aural*—volume of tone mistaken for depth, brightness for height.

Illustrated by voices, instruments and diagrams.

MARCH 1.—"The British Art Section of the St. Louis Exhibition." By ISIDORE SPIELMANN, F.S.A. SIR EDWARD POYNTER, Bart., P.R.A., will preside.

Dates to be hereafter announced:—

"The Protection of Buildings from Lightning." By KILLINGWORTH HEDGES, M.Inst.C.E.

"The Present Aspect of the Fiscal Question." By SIR CHARLES MALCOLM KENNEDY, K.C.M.G., C.B.

"British Woodlands." By the RIGHT HON. SIR HERBERT MAXWELL, Bart., M.P.

"The Supply of Electricity." By JAMES NELSON SHOOLBRED, B.A., M.Inst.C.E.

"Lake Baikal and its Connection with the Great Siberian Railway." By ARTHUR GULSTON.

"Application of Electricity to the Location of Mineral Deposits." By ALFRED WILLIAMS.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

FEBRUARY 16.—"The Indian Census of 1901." By SIR CHARLES A. ELLIOTT, K.C.S.I., LL.B. The RIGHT HON. LORD GEORGE HAMILTON, G.C.S.I., M.P., will preside.

MARCH 16.—"Manipur and its Tribes." By T. C. HODSON (late I.C.S.).

APRIL 6.—

MAY 11.—"The Manufactures of Greater Britain. —III. India." By HENRY JOHN TOZER, M.A.

COLONIAL SECTION.

Tuesday afternoons at 4.30 o'clock:—

JANUARY 24.—"British Commercial Prospects in the Far East." By BYRON BRENAN, C.M.G., late H.B.M. Consul-General at Shanghai. SIR EDWARD A. SASSOON, Bart., M.P., will preside.

FEBRUARY 28.—"The Manufactures of Greater Britain.—I. Canada." By C. F. JUST, Canadian Government Service in London.

MARCH 28.—The Manufactures of Greater Britain. —II. Australasia." By the HON. WALTER HARTWELL JAMES, K.C., Agent-General for and late Premier of Western Australia.

MAY 23.—"The Cape to Cairo Railway." By SIR CHARLES H. T. METCALFE, Bart., M.Inst.C.E.

APPLIED ART SECTION.

Tuesdays, at 4.30 or 8 o'clock:—

JANUARY 31, 8 p.m.—"Calligraphy and Illumination." Two Papers. By EDWARD JOHNSTON and GRAILY HEWITT. LEWIS FOREMAN DAY, Vice-President of the Society, will preside.

FEBRUARY 21, 8 p.m.—"The Queen Victoria Memorial as compared with other Royal Memorials." By MARION H. SPIELMANN, F.S.A. JOHN BELCHER, A.R.A., President of the Royal Institute of British Architects, will preside.

MARCH 21, 8 p.m.—"West Country Screens and Rood Lofts." By F. BLIGH BOND, F.R.I.B.A. G. F. BODLEY, R.A., will preside.

APRIL 11, 4.30 p.m.—"The Monumental Treatment of Bronze." By J. STARKIE GARDNER. SIR GEORGE BIRDWOOD, K.C.I.E., C.S I., will preside.

MAY 16, 4.30 p.m.—"Popular Jewelry." By MONSIEUR LALIQUE (Paris). ARTHUR LASENBY LIBERTY, J.P., will preside.

CANTOR LECTURES.

Monday evenings, at 8 o'clock:—

JAMES P. MAGINNIS, Assoc.M.Inst.C.E., M.Inst.Mech.E., "Reservoir, Stylographic, and Fountain Pens." Three Lectures.

LECTURE I.—JANUARY 23.—*Ancient Writing Implements.*—The Stylus and Tabula—Calamus or reed pen—Stencil—Quills, quill nibs, attempts to make quills more serviceable—Substitutes for quills—Silver pens—Ink horn and penner—Ancient writing outfit—Eastern writing implements—Survival of ink horn—Japanese writing box and pens—Their portable writing set—Early metal pens—Steel pens—Barrel pens—First patent for metallic pens—Improvements in steel pens with the object of increasing their ink-holding capacity — Reservoir nibs, various illustrations.

LECTURE II.—JANUARY 30.—*Stylographic Pens.*—Rudimentary forms—Early patents—Rigid points, needle points—Various writing or marking pens—Modern Stylographic pens, Nota Bene, Cygnet, and others—Gold pens, description of manufacture.

LECTURE III.—FEBRUARY 6.—*Fountain Pens.*—Early patents—Solid ink—Various reed arrangements — Self-filling reservoirs, flexible reservoirs, piston and plunger—Modern types of Fountain pens, Swan, Ideal, Conklin, Pelican, Unleakable, Wirt, Quill, Post, Autofiller, Fleet, &c.

DUGALD CLERK, "Internal Combustion Engines." Four Lectures.

February 13, 20, 27, March 6.

HERBERT LAWS WEBB, "Telephony." Four Lectures.

March 13, 20, 27, April 3.

ALAN S. COLE, C.B., "Some Aspects of Ancient and Modern Embroidery." Two Lectures.

May 1, 8.

HENRY WILLOCK RAVENSHAW, Assoc. M.Inst.C.E., Mem.Fed.Inst.Min.Eng., "The Uses of Electricity in Mines." Two Lectures.

May 15, 22.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JAN. 23...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Mr. James P. Maginnis, "Reservoir, Stylographic, and Fountain Pens." (Lecture I.)

Geographical, University of London, Burlington-gardens, W., 8½ p.m.

British Architects, 9, Conduit-street, W., 8 p.m. Mr. James Ransome, "European Architecture in India."

Camera Club, Charing-cross-road, W.C., 8½ p.m. Mr. Alfred East, "A Landscape Painter in Japan."

Medical, 11, Chandos-street, W., 8½ p.m.

London Institution, Finsbury-circus, E.C., 5 p.m. Mr. Hugh Stannus, "Architecture from Egypt to Rome."

TUESDAY, JAN. 24...SOCIETY OF ARTS, John-street, Adelphi, W.C., 4½ p.m. (Colonial Section.) Mr. Byron Brenan, "British Commercial Prospects in the Far East."

Royal Institution, Albemarle-street, W., 5 p.m. Prof. L. C. Mialls, "The Structure and Life of Animals." (Lecture II.)

Medical and Chirurgical, 20, Hanover-square, W., 8½ p.m.

Civil Engineers, 25, Great George-street, S.W., 8 p.m. 1. Mr. James Forest Brunton, "Notes on the Working of the Shone System of Sewerage at Karachi." 2. Messrs. Edmund Herbert Stevenson and Edward Kynaston Burstal, "The Sewerage of Douglas, Isle of Man."

Anthropological, 3, Hanover-square, W., 8½ p.m. Annual Meeting.

WEDNESDAY, JAN. 25...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Hon. Robert P. Porter, "London Electric Railways."

Royal Society of Literature, 20, Hanover square, W., 8½ p.m.

British Astronomical, Sion College, Victoria-embankment, E.C., 5 p.m.

THURSDAY, JAN. 26...Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

London Institution, Finsbury-circus, E.C., 6 p.m. Mr. Hilaire Belloc, "The Growth of a City—London."

Royal Institution, Albemarle-street, W., 5 p.m. Prof. Churton Collins, "The Philosophy and Significance of 'The Tempest'."

Electrical Engineers, 25, Great George-street, S.W., 8 p.m. Discussion on Messrs. W. H. Booth and J. B. C. Kershaw's papers, "Fuel Economy in Steam Power Plants."

Camera Club, Charing-cross-road, W.C., 8½ p.m. Dr. Vaughan Cornish, "Wave Phenomena."

FRIDAY, JAN. 27...Royal Institution, Albemarle-street, W., 8 p.m., Weekly Meeting. 9 p.m., Mr. A. E. Wilson, "The Life of the Emperor Penguin."

Civil Engineers, 25, Great George-street, S.W., 8 p m. (Students' Meeting.) Mr. T. L. Matthews, "Concrete-making on the Admiralty Harbour Works, Dover."

Architectural Association, 18, Tufton-street, Westminster, S.W., 7½ p.m. Messrs. J. B. Fulton and E. F. Reynolds, "Byzantine Architecture."

Clinical, 20, Hanover-square, W., 8½ p.m.

Physical, Royal College of Science, South Kensington, S.W., 5 p.m. 1. Dr. R. S. Willows, "Action of a Magnetic Field on the Discharge through a Gas." 2. Dr. R. S. Willows and Mr. J. Peck, "Action of Radium on the Electric Spark." 3. Mr. P. Phillips, "The Slow Stretch in India-rubber, Glass, and Metal Wires when subjected to a Constant Pull." 4. Mr. C. A. Bell, "Determination of Young's Modulus for Glass." 5. Dr. Boris Weinberg, "Some Methods for Studying the Viscosity of Solids."

Botanic, Inner Circle, Regent's-park, N.W., 3¾ p.m.

SATURDAY, JAN. 28...Royal Institution, Albemarle-street, W., 3 p.m. Prof. Charles Oman, "Wat Tyler in London." (Lecture II.)

Journal of the Society of Arts.

No. 2,723. VOL. LIII.

FRIDAY, JANUARY 27, 1905.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C

NOTICES.

NEXT WEEK.

MONDAY, JANUARY 30, 8 p.m. (Cantor Lecture.) JAMES P. MAGINNIS, "Reservoir, Stylographic, and Fountain Pens." Lecture II.

TUESDAY, JANUARY 31, 8 p.m. (Applied Art Section.) EDWARD JOHNSTON and GRAILY HEWITT. Two papers on "Calligraphy and Illumination."

WEDNESDAY, FEBRUARY 1, 8 p.m. (Ordinary Meeting.) SIR WILLIAM H. PREECE, K.C.B., F.R.S., "The Navigation of the Nile."

Further details of the Society's meetings will be found at the end of this number.

EXAMINATIONS.

The Society's Examinations will commence Monday, April 10th.

As previously announced, important changes have been made in the Examinations this year. These changes, however, affect the classification of the candidates only, not the general system of organisation.

There are now three Divisions or Stages:—
1. Elementary. 2. Intermediate. 3. Advanced.

The Examination papers for the three Stages will be separate and distinct. Candidates failing in the Advanced or Intermediate will in no case be granted a lower Stage certificate.

Candidates who have not previously passed in the Society's Examinations are strongly recommended to enter in the first instance for the Intermediate Stage.

Candidates who have already passed the

	Monday, April 10. (7—10 p.m.)	Tuesday, April 11. (7—10 p.m.)	Wednesday, April 12. (7—10 p.m.)	Thursday, April 13. (7—10 p.m.)	Friday, April 14. (7.15—10 p.m.)
Advanced Stage.	Accounting and Banking. Portuguese. Précis-writing. Russian. Chinese. Japanese. Hindustani.	Arithmetic. Commercial Law. German. Italian. Spanish.	French. Commercial History and Geography. Typewriting (7.30 to 10 p.m.).	Book-keeping. English. Economics. Danish.	Shorthand (7.15 to 10 p.m.)
Intermediate Stage.	Arithmetic. German. Portuguese. Italian. Russian. Chinese. Japanese. Hindustani.	Book-keeping. Précis-writing.	English. Economics. Spanish.	Typewriting (7.30 to 10 p.m.). French. Danish. Commercial History and Geography.	Shorthand (7.15 to 10 p.m.)
Elementary Stage.	German. Typewriting (7.30 to 10 p.m.).	Handwriting and Correspondence. French. Italian.	Book-keeping Spanish.	Commercial Geography. Arithmetic.	Shorthand (7.15 to 10 p.m.)
Music.		Harmony.	Rudiments of Music (7 to 9 p.m.).		

Second-class or Third-class of the old Grade II. and have made progress, ought to be able to take the Advanced Stage.

The papers set will be of the same character as those of previous years, which will therefore, as hitherto, form a useful guide to the nature and scope of the Examinations.

The following new subjects have been added:—

Elementary Stage—Italian.

Intermediate Stage—Hindustani.

Advanced Stage—Commercial Law. Accounting and Banking, Hindustani.

In the Advanced and Intermediate Stages First and Second-class Certificates will be granted in each subject.

In the Elementary Stage Certificates will be given in each of the subjects enumerated. These will be of one class only.

Certificates of proficiency will be granted to each grade to Candidates who pass in certain specified subjects during a given period.

In Rudiments of Music Higher and Elementary Certificates are given; in Harmony, Higher, Intermediate and Elementary Certificates.

A fee of 2s. 6d. will be required by the Society from each Candidate in each subject in the Advanced and Intermediate Stages, and in the Elementary Stage a fee of 2s. for one subject, and 1s. for each additional subject taken up by the same candidate. The fees for Harmony and Rudiments of Music are the same as for Stages II. and III.

Medals and Prizes are offered in each subject in Stages II. and III. Full particulars will be found in the Programme.

In choosing the subjects in which they desire to be examined, candidates must take notice of the arrangements of the Time-table, as they cannot be examined in more than *one* subject on each evening. The days and hours of Examination must be *strictly* adhered to.

Examinations are also held in the Practice of Music, and Vivâ Voce Examinations in French, German, Spanish, Portuguese, and Italian. For information as to these examinations reference should be made to the Programme.

The Time-table of the Examinations for this year is given on the preceding page.

The Programme for the present year can be had, price 3d., on application to the Secretary, Society of Arts, Adelphi, London, W.C.

CANTOR LECTURES.

On Monday evening, 23rd inst., Mr. JAMES P. MAGINNIS delivered the first lectures of his course on "Reservoir, Stylographic, and Fountain Pens."

The lectures will be published in the *Journal* during the summer recess.

COLONIAL SECTION.

Tuesday, January 24, 1905; Sir EDWARD A. SASSOON, M.P., in the chair.

The paper read was "British Commercia Prospects in the Far East," by BYRON BRENAN, C.M.G., late H.B.M. Consul-General at Shanghai.

The paper and report of the discussion will be published in a future number of the *Journal*.

PROCEEDINGS OF THE SOCIETY.

SEVENTH ORDINARY MEETING.

Wednesday, January 25, 1905; The RIGHT HON. LORD GEORGE HAMILTON, G.C.S.I., M.P., in the chair.

The following candidates were proposed for election as members of the Society:—

Anderson, David, Ashdale, Satanita-road, Westcliff-on-Sea.

Childs, Harry, 47, London-street, Reading.

Dawbarn, Alfred H., 1, St. James's-place, S.W.

De-la-Motte, Freeman Alexander, Cadnant-park, Conway.

Gabbett, Edward, Public Works Department, Maymyo, Burma.

Hobhouse, Mrs., The Ridge, Corsham, Wilts.

Hyde, John, Lanier Heights, Washington, D.C., U.S.A.

Kodandaramiah, Khajana; Sompet, Ganjam District, Madras, India.

Macaulay, Thomas F., Rosbrien-house, Limerick, Ireland.

Mahler, Miss E., Sudworth, New Brighton, Cheshire.

Morris, Steven William Savin, P.O. Box 691, Cape Town, South Africa.

Munro, Laurence, Kronsbein-building, 10, Main-street East, Hamilton, Ontario, Canada.

Pottie, George, 42, Mansfield-road, Ilford, Essex.

Powell, A. H., Neston, King's-avenue, Ealing, W.

Rees, John David, C.I.E., 17, Pall-mall, S.W.
Sadler, Henry Knight, 5, St. Andrew's-place, Regent's-park, N.W.
Slessor, Major Herbert, R.M.A., Eastney Barracks, Portsmouth.
Smith, Harold Bayldon, A.R.I.B.A., 11, Constitution-hill, Port Elizabeth, Cape Colony, South Africa.
Straker, Donald, Haslemere, Surrey.
Waugh, Percival Bentley, Whitehall Club, Parliament-street, S.W.
Whitehead, Sydney, 24, Queen's-road, Wimbledon, S.W.

The following candidates were balloted for and duly elected members of the Society:—

Bayley-Worthington, A. B., 8, Balfour-place, Mount-street, W.
Deadman, Thomas W., 58, Northcote-road, St. Margaret's, Twickenham.
Forbes, David, 5, Benedict-road, Brixton, S.W.
Hatschek, Emil, A.M.I.Mech.E., 24, West Twenty-fifth-street, New York City, U.S.A.
Haynes, Josiah Edward, Union Offices Stroud and Paganhill, Stroud, Gloucestershire.
Kerr, Rennie Malcolm, Gokak Falls, Belgaum District, India.
McLaren, William David, A.M.I.Mech.E., Thomason Engineering College Workshops, Roorkee, India.
Mitchell, Arthur Edward, 10, Lower Mount Pleasant-avenue, Rathmines, Dublin.
Nicholls, Captain Alfred Edward, Cotswold, Hornchurch, Essex.
Reynolds, Major James M., Burdett, New York, U.S.A.
Weiskopf, Alois, 3, Sophienstrasse, Hanover, Germany.
Wharton, William Hewley, L.R.C.P., 1, Brick dam, Georgetown, Demerara, British Guiana.
Wilson, George Lewis, 522, High-road, Tottenham, N.

The paper read was—

LONDON ELECTRIC RAILWAYS.

BY THE HON. ROBERT P. PORTER.

Cities, like individuals, differ so widely and so fundamentally, that what suits one is not adaptable to another; that, in short, the system of locomotion possible and successful in one city, may not be practical, or may prove a failure in another. One might compare existing conditions in London with those of New York, Paris, Berlin, Chicago, Glasgow, Vienna, Buda-Pest, Philadelphia, Hamburg, Liverpool and Boston, with a very small percentage of practical results. For nearly two years a Royal Commission has been sitting at intervals and gathering information on London traffic. In the course of its inquiries some of its members have visited these cities; but it would be interesting to know how much of practical value they brought away with them that can be applied to the conditions that confront us in dealing with rapid transit in London. I do not contend that it is unimportant for those dealing with London traffic to be acquainted with what other cities are doing in this direction, or to ascertain by what agencies difficulties are being met. Such information is of value if only to show what not to do; but I am of the opinion that after all this information has been obtained, we come back to the original problem of London and how to relieve its congested streets—a problem which can only be successfully worked out by methods in harmony with existing conditions, and not by grafting methods which have been developed under entirely different conditions elsewhere.

To further illustrate this, it is only necessary to glance at some of the maps of the larger cities of the world, and to note their physical variations. One authority thinks he discerns that nearly all large cities are laid out and developed on one of three distinctive plans (each plan requiring a different general system of transport routes to serve its population), namely, the peninsula, the valley, and the radiating plan. I think these divisions may be increased by introducing the "semi-radiating." The peninsula plan has a water front on both sides, such as New York, San Francisco, and Stockholm. The valley plan has a river running through the centre, and the most populated and business districts on both sides of the river, such as Pittsburg and Rome; the semi-radiating plan, with territory on one side of the water front, such as Chicago, Liverpool, St. Louis, Boston, Brooklyn, Milwaukee, and other cities of lesser importance. It is hardly fair to classify such cities in the radiating plan, because unlike London, Paris, Berlin, Glasgow, Manchester, their radiation is entirely on one side. Aside from geographical considerations, there are geological conditions, which though overcome to a considerable extent by modern engineering, have made it difficult, if not impossible, to accomplish engineering construction in one city that has been comparatively easy in another. Especially has this been the case in underground work, in which the clay soil of parts of London has made both tunnelling and tube railways practicable, while, until

quite recently the solid rock on which New York is built, was an obstacle for tube work, and extremely difficult for shallow subways. I remember, when the first subway in Boston was projected, the grave doubts that were entertained by the engineers as to the successful issue of excavating the sandy soil upon which that city is built, and the fears lest the work should undermine the foundations of buildings. Again, few people who knew Chicago immediately after the fire, and watched the enormous amount of pile driving (reminding one of Amsterdam) which preceded the construction of the large public buildings and blocks of that city, would believe that at a level of 40 feet below the surface, an enterprising company has practically duplicated the street of the entire business district. When recently in Chicago, I was given the plans of Bion J. Arnold, a well-known engineer, who has been employed to furnish a scheme for the further relief of traffic in the congested districts of Chicago, in which he proposes (in addition to these freight tunnels already constructed) as the best plan a combination of north and south high level subways, with three or more low level subways with lifts similar to those in London, as the most practical method.

But aside from physical difficulties in the treatment of rapid transit of modern cities, there are political, and in continental Europe, military exigencies, which enter largely into the problem. The agitation for underground railways in Paris began in the fifties, about the time when the first metropolitan underground section from Paddington to Farringdon-street was constructed and opened. The principal reason of the opposition of the municipality of Paris to underground railways was one that might be regarded as the strongest reason for adopting them in London, namely, that they took people outside the city boundaries into the suburbs. This was a curious attitude—to oppose new railways because they would prove of public convenience; but it will be readily understood when it is explained that such facilities would involve a serious interference with the octroi tax (the chief source of municipal revenue) by effecting a large transference of homes beyond the octroi. So for a generation or more underground railway schemes slumbered in Paris, and a variegated assortment of trams and omnibuses and motors, with every sort of propulsion known to the human race, have struggled with a varying degree of success with the street passenger traffic.

Turning to Berlin, it would be impossible, in glancing at the map of that city, not to observe that military considerations, as in Paris, had a much larger share in the design of the Ringbahn, or "Circle" Railway, opened in 1877, than any desire to facilitate the passenger traffic.

Rapid Transit Incubates Slowly.

As it is my purpose briefly to discuss underground electric railways in the solution of the traffic problem of London, it is not necessary to do more than refer to the underground systems in other cities, because London may be regarded as the home of them all, both tunnels and tubes. Nor is it necessary to remind this audience that the elementary scheme for the construction of a metropolitan underground railway was projected more than sixty years ago, and after seventeen years of agitation, the first Bill for the construction of the Metropolitan Railway (the section between Paddington and Farringdon) was passed in 1854. The work was not begun until six years later (in 1860), but once started, it was pushed on rapidly, and the line opened for traffic in 1863. Here we have the nucleus of the underground systems, which were increased from time to time very much on the instalment plan, and nearly a generation had passed away before the final link of the Inner Circle, comprising the Metropolitan and Metropolitan District Railway, was completed. However impatient we may sometimes be with the present generation, it would be as well for our nerves perhaps if we occasionally revived the memories of the long protracted controversies of our fathers. However fast we may travel when all the work now in progress of completion is open for traffic, and all the recommendations of the Royal Commission on London Traffic now under consideration are carried out, and all tracks of the surface railways entering and crossing London are electrified, history tells us that rapid transit incubates slowly, and requires much careful nursing in order to bring it to a healthy and vigorous maturity. Paris, as I shall presently show, has been nearly a half a century developing its Metropolitan Underground Railway. New York, with all its new world energy, appointed commissions and talked for nearly a quarter of a century before it got down into the rock and built its subway; and even the breezy city of Chicago allowed that well-known street railway expert (Mr. Yerkes) to come and go before it seems to have discovered that below the

juicy mud into which it had driven piles to hold up sky-scrapers, was a clay as good, if not better, than that of London, through which to cut its tunnels. No! Whatever may be said of the condition of the underground railways of London when the electrification was undertaken by the joint enterprise of England and America, the Inner Circle was for its time a monumental work of engineering. In this, as in so many other branches of constructive engineering enterprise, England showed the way for other countries to follow. To be sure this assertion has been qualified a little by my friend, Mr. James Dredge, the Editor of *Engineering*, who recently said, "It is our way, when we have completed some great work, to be so satisfied with the completion and execution that we leave it to remain unaltered, a great monument, forgetful of the fact that such monuments mark the graves of progress." But in the case of the Metropolitan and the District, this does not apply, for the present year we hope will find them altered.

The First Tubular Railway.

From the first underground railways, we naturally turn to the first tubular railway which was made possible by the application of electricity for traction purposes, and we find it to be purely a British idea, and first put to practical use in London. An interesting account of the origin of tubular railways appeared a year or two ago in the testimony of Sir Benjamin Baker before a Parliamentary Committee:—

"Mr. Charles Gras Mott, Chairman of the South London Railway (said Sir Benjamin Baker), came one day and told me that he proposed to go to Parliament for a tube railway from Stockwell to the City, going under the Thames by London Bridge. Undoubtedly the present state of the tube mania, as you may call it, dates from that time. I told Mr. Mott that there would be a tremendous parliamentary opposition, because it was a novel affair; questions would be raised of damage to property, damage to London Bridge and all the other things. And so it turned out; but, however, after great hesitation, the Act was granted. The late Mr. John Walter, M.P., of *The Times*, was the Chairman of the Committee, and I remember he told me the day after that he was so anxious about it, and about the danger of making these tube railways, especially as regards London Bridge, that he went at 5 o'clock in the morning and stood on London Bridge and pictured to himself London Bridge tottering, and then he thought after a while, that if this thing be a great success it would lead to a great development, and he finally hardened his heart, and he passed the City and South London. That is the origin of all these tube railways. English engineers are reproached for want of enterprise, but they cannot be reproached in this respect. This is solely a British idea."

Through the courtesy of Mr. Thomas, of the *Graphic*, and Mr. Jenkin, General Manager of the City and South London, I am able to present slides showing the ceremonies at the opening of the first London tube, November 4th, 1890, upon which occasion Mr. Mott, the present chairman, took the chair, and the King (then Prince of Wales) made a speech, in which, among other things, he said:—

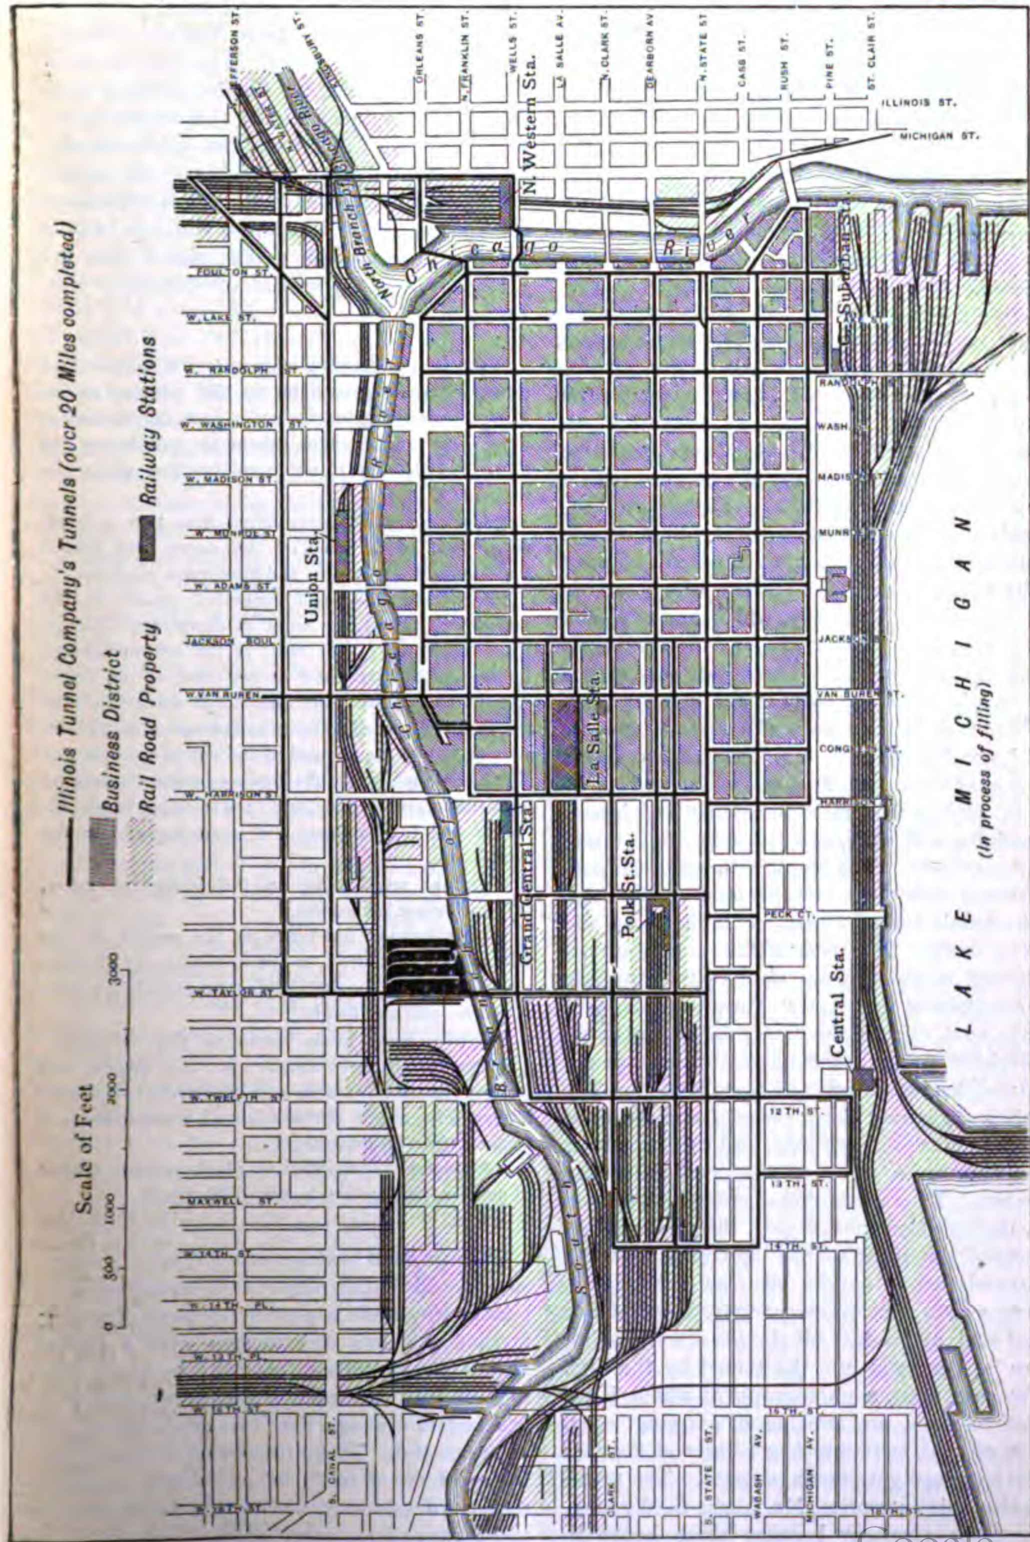
"I have also to return you my thanks for having given me the opportunity to be here to-day, and to have inaugurated a work which I have little doubt will be of the greatest use to the community at large, and especially a great boon to this great metropolis. It must be a matter of sincere thought to all of us, the ever-increasing growth of this great metropolis, with its means of access, owing to the great increase in the population, becoming more and more difficult. Therefore this railway to-day, this first electric railway which has been started in England, will, I hope, to a very great extent do much to alleviate the congestion of the traffic which now exists, so that business men who have a great distance to go will find easy means of getting away from this great city and enjoying the fresh air of the country; and that it will also be a great boon to the working men who are obliged to work in an unpleasant atmosphere, who will be able to get away for a little fresh air. Not only is this railway a very remarkable one from a scientific point of view, but it has this great advantage, that it has two tunnels. This is distinct from the one tunnel which characterises the present underground railway; and also the advantage that it has netiher smoke nor steam, and ample ventilation."

There were many difficulties experienced in the promotion, construction, and equipment of the first electric tube, and it was not until Mr. C. G. Mott, a director of the Great Western Railway, became chairman, that the money was raised, and the work fairly began. Electric traction was then in its infancy, and various plans were discussed and abandoned before a satisfactory system was at length worked out. It was at first proposed to place the motors at each end of the train, but subsequently, fearing the Board of Trade might object to this arrangement, it was determined to put both motors on a separate vehicle of light weight, which could be easily attached and detached from the trains. This was the form finally adopted, and the railway has been worked on this principle ever since it was opened, and the arrangement being recognised as efficient and economical,

its use has spread far and wide both in this country and abroad. No objection being now raised by the Board of Trade, the motors on most of the other railways are being placed on the carriages of the train, but the City and South London still adhere to the separate locomotives, the general manager believing they have an element of safety, and are as efficient in working. The railway has now been extended to Clapham Common on the south, and to the "Angel," at Islington, on the north; and a further extension to King's-cross, St. Pancras, and Euston, is in progress of construction.

THE NEW TUNNELS OF CHICAGO.

Having given full credit to the British metropolis for inaugurating underground and electrical tubular railways and to British engineers for first putting them in operation, you will pardon me if I digress in order to call attention to some interesting work I have recently inspected in other cities, notably New York, Chicago and Boston, and to what is going on in the construction of underground railways in Paris and Berlin. Not that I think these undertakings have much bearing on the present solution of the traffic problem of London, but they are, in themselves, instructive and enterprising experiments well worth a reference on this occasion. First, we will take Chicago, because that go-ahead city has evolved and really put into operation something original in the way of electrical underground transportation. The idea seems to be "the streets for the people, the tunnels for merchandise, coal and freight." We heard something of this kind last year before the Royal Commission on London traffic from Sir Henry E. Knight, who, you may remember, proposed to construct a tube under London large enough to enable whole truckloads, by means of lifts or inclines, to be sent on the tube lines without any transhipment at the goods stations. At the time, this proposal seemed to strike the London daily press as humorous, but in Chicago it is being strongly urged as sensible and practical. If such a scheme as this were put into force it might relieve the streets of the crawling vans, and of that hideous innovation, the motor lorry. Another reason why this motto appealed to Chicago was that the promotors ingeniously announced their intention at the psychological moment, after a protracted strike of drivers and truckmen, during which the strikers refused to permit the dead, conveyed by non-union men, to be driven to the cemetery. But I am getting a little ahead of my story and must describe the new Chicago tunnels and the condition of affairs which has produced them. The growth of population in Chicago has, as you know, been very great and very rapid. At the time the first section of the London Underground was opened, the population of Chicago was about 150,000. To-day it is more than two millions. So you will see that they have had to move a little more rapidly in their undertakings to meet this increase of population than has been necessary in some of the older cities. From 1837, when Chicago first appears as having any population at all, to 1902, the average rate of increase in the population has been a little over $8\frac{1}{4}$ per cent. per annum. London during this last half century has increased in population about $1\frac{1}{4}$ per cent. per annum. The increase of railway mileage centreing in Chicago has been as great, and in 1902 that mileage so centreing and having its termini in the city amounting to not less than 40 per cent. of the entire railway mileage of the United States. As you will see from the map, these railways all pour in their freight and passengers in sections of the city fronting along the river, which has an unfortunate fault, so the Chicago people think, of running both north and south, and east and west, and hence it must be crossed in many directions. The city, therefore, is divided into three divisions. This water barrier has been the fixed condition that has been recognised and referred to. Town divisions were established on its lines and its boundary divides all wards throughout its course. The water, gas and sewage systems are laid out with regard to it. Diagonal streets or avenues to the business centre are determined by its course. In short, it is primarily responsible for the congested condition of the business centre, honeycombed with freight depôts, limiting as it does by its moveable bridges its area to a little more than a square mile, that is, the section within the area besieged as it were by these railways, about a mile wide and a mile and a half long. It goes without saying that the manufacturing district has grown up along the course of this river, and naturally all lines of business that can be more profitably conducted by navigation have sought its frontage, while the Lake Shore is being appropriated for parks and pleasure gardens. The banks of the three branches of the river have been built up by all sorts of industries, and the whole area forms a concen-



Emery Walker sc.

Underground Railways of Chicago.

tration of freight and traffic business that would be difficult to find in almost any other city of the world. The value to a district of this sort of a duplicate of all its thirty miles of streets, forty feet below the surface, is naturally great. Here, then, is what I found, to my surprise, when in Chicago last month. The story of the construction of these tunnels is perhaps the most interesting and picturesque branch of underground railway building that we are likely to touch upon this evening. While Chicago may have been a long while in discovering the value of underground railways, after that discovery was made, the promoters of the enterprise lost no time in carrying it out. Work on the tunnels was commenced on the 3rd September, 1901, and in 12½ months from the date of actual work, 12 miles of tunnel were completed, making an average of more than a mile of tunnel per month. Last September, three years after the inauguration of the work, over 30 miles of these tunnels were finished and equipped with rails and overhead electric wires, and the Illinois Tunnel Company, which has exploited this enterprise, expects to have it completed and ready to deliver not less than 50,000 tons of freight each day early in the present year. These tunnels have walls of concrete, and are of horseshoe shape. They are of two sizes; trunk conduits, 12 ft. 9 in. wide, and 14 ft. 6 in. high, inside measurements; and lateral conduits, 6 ft. wide, and 7 ft. 6 in. high, inside measurement. The smaller tunnels are constructed with 13 in. bottoms and 10 in. walls. The trunk tunnels have 21 in. bottoms and 18 in. walls. The roofs of the tunnels are not allowed to come closer than 24 ft. 6 in. from the surface of the street. These tunnels, as I have said, contain the cables for an automatic telephone system now in operation, and already serving between 4,000 and 5,000 stations. The cables are strung along the roof and the walls of the tunnel on each side, and room is left on the floor for a track or tracks of a railway system. By an additional ordinance, passed by the City Council last year, the company has secured the right to use apparatus for the transmission of freight, such as newspapers, mail matter, packages, parcels, merchandise and coal, and in fact all classes of freight that can be conveyed into the tunnel by the lifts. The cars used, a photograph of which I am able to show, are capable of carrying seven tons of coal, or twenty-four barrels of flour, or two large upright pianos in cases. The president of this enterprise, Mr. Albert G. Wheeler, in whose company I spent three hours in these tunnels, informed me that he had already made a number of contracts for the supply of coal to the large business blocks, hotels, manufactories, &c., in this district. You will no doubt be wondering how these tuunels are to be operated, and the answer to this question I will leave to the gentlemen who have promoted and carried out the undertaking. We have here their advertisement, in the crisp, terse inimitable Chicago way of putting it before the public, taken from the *Chicago Daily Journal* of October, 31st, 1904:—

"*What the Subway means to Chicago.*—Clean streets, pure air, sunlight for the people, underground subway for freight traffic, just the reverse of New York and London, where the people are put underground, and teaming and trucking given the preference.

"Coal, ashes, dirt, excavations from new building sites, offal, &c., taken off the streets and hauled underground, all the dirt and annoyance abolished.

"Relief for the most congested district in the world, in 1½ square miles of downtown Chicago there is centred 35 per cent. of the railway mileage of the United States and 14 per cent. of the entire world's mileage, the terminals of 38 truck line railroads. In this small territory an average of 40,300,000 tons of freight are shipped in and out in one year.

"Every building in the business district equipped with tunnel connections, and thus in direct communication with every railroad and steamship line in the world.

"Freight, merchandise and fuel hauled in, ashes, dirt and refuse hauled out.

"Uninterrupted free traffic on the surface for the people who walk, drive, or ride in surface and elevated cars—the streets for the people, the tunnels for merchandise, coal and freight.

"While New York boasts of the 'Subway,' Chicago quietly goes ahead with the largest and longest system of tunnels ever constructed—12 miles longer than any in the world—and many miles still under way to be constructed.

"A system unparalleled in all the world—typical of modern, progressive, hustling Chicago."

Chicago itself having spoken, it is only necessary to add that a company representing on its board many of the important railways centreing in that city, has been formed with a capital of £10,000,000 to take over the property from the original construction company, and it is believed in Chicago that the experiments will be successful. Those interested in these problems of street traffic of cities will naturally watch its development with considerable interest and perhaps some speculation.

Rapid Transit Work in New York.

Passing from Chicago to New York, it is not my intention to describe the various systems of rapid transit of that city any more than it has been my aim to do in the case of Chicago, but merely to add a few words describing the operation of the new subway which was opened a few months ago, and to refer to some of the additional undertakings now in progress of completion which have for their purpose the improvement of the existing facilities in this city. As a matter of fact, it may be said of New York that from the Battery to 150th Street it is a perfect gridiron of mechanical traction. To be sure, there are many cross-town horse-cars still remaining in wards called the down town district, but there are ten or a dozen longitudinal surface tramways with their cross-town connections, which carry in the neighbourhood of 600 million passengers annually, and none of these railways appear on the map of New York, to which I shall call your attention. The map shows only the elevated railways, the subways present and proposed, the New York Central Railway tracks, and the important improvements already inaugurated by the Pennsylvania Railway Company. Two sections of the subway have now been completed and opened. These sections comprise the first of the subway schemes. The construction work was begun on March 24th, 1900, and completed in a little over four years, the second section being opened while I was in New York. The contract covered the construction of a four-track subway from City Hall to 96th Street, a distance of 6·71 miles, an extension to the west side of the City of Kingsbridge, made up of 3·85 miles of three-track construction, and three miles more of two-track construction; and an extension on the east side of the city to Bronx-park of 2·89 miles of three-track and 4·24 miles of two-track construction, making a total of 20·69 miles of subway and elevated structure, providing for 63 miles of single track.

It is sometimes assumed that these 20 miles are all subway, but such is not the case. There are 10½ miles of subway, built with steel columns supporting the streets ("cut and cover" lines laid within a few feet of the street surface), 4½ miles of concrete arch construction (*i.e.*, tunnel work through hills or elevation or under streets where underground tracks had to be avoided), and 5 miles of elevated structure (*i.e.*, the viaduct at the extreme north ends of the two branching lines). The local service consists of five-car trains, which run on a one minute headway on the main part of the line, with alternative trains to each branch. The contract calls for a speed of 14 miles an hour from end to end of the line, but this if anything is, I think, exceeded. The average distance between the stations is 2,300 feet. The photographs, which have been kindly given me specially to be used at this lecture by Mr. Barclay Parsons, the chief engineer of this important work, will give you some idea of the New York subway trains in operation. The cars are very comfortable, and it is surprising how quickly the motor men and other officials have taken up this new business, for unlike the electrification of the existing railways here, and for that matter, the electrification of the Manhattan, the New York subway was started up as it were in the night, whereas in cases of electrification of steam railways, the electric trains run for a time interspersed with steam locomotives, and the change is gradual. The whole thing works as smoothly as if it had been going on for a number of years. I find the express trains running at average speeds of thirty miles an hour, specially convenient in reaching points like 72nd and 95th Streets. You can save time if you are going to an intermediate station, some distance from the business section of the city, by taking an express train to the nearest station, and a local train which stops at every station.

Work under Construction in New York.

On the map, which we are looking at, is shown not only the new subway as in operation, but the proposed lines which in all probability will soon be under construction, for I note in a cable despatch from New York that the last report of the engineer of the Rapid Transit Commission, who has this matter in charge, will probably be put into effect. This will give another line from the down town district to connect with the present subway at 42nd Street. It will also give another line along Lexington-avenue towards the East River. There will also be some linking up in what is called the Borough of the Bronx, and an extension beyond the present termini in that division, in the direction of White Plains. I also call attention on this map to what are called the Hudson River Tunnels, connecting New York or Jersey City and New York with Hoboken; the first of these tunnels goes under the river from Hoboken to Christopher-street, and the second from Ex-

changer-place, Jersey City, to Church and Cortland-streets, in New York.

This brings us to the important work which the Pennsylvania Railway Company is doing in New York, some idea of which may be gathered by the admirable photographs which were presented to me specially for this paper by Mr. George Gibbs, a member of the committee of the engineers appointed to superintend the work. By this enterprise, a solution of the problem of the physical connection of New York City with the trunk lines terminating on the west bank of the Hudson in Jersey City, will be solved, as well as a through connection without ferry transfer with Long Island. The single length of its tunnel line from its portal in New Jersey to its portal in Long Island will be 5·6 miles, and in this distance there are to be somewhat over 15 miles of single track tunnels. Long Island, as many present are aware, is not only an excellent summer residential stretch of country bounded on the west side by the Atlantic Ocean, on the other by Long Island Sound, but Montawk Point is about 200 miles nearer Queenstown than New York, and it has long been the cherished idea of certain enterprising railway men in America to make this the port of departure for some of the large ocean liners. These important tunnels of the Pennsylvania Railway Company, completed so as to make a direct rail route from any part of the United States under both the rivers and New York, make the journey by water considerably less. The Pennsylvania Railway Company has acquired the entire Long Island Railway system which runs along both shores with a third track through the centre of the island. The amount of lighterage saved by these important constructions, to say nothing of the additional convenience to passengers, will be enormous. It is said that the cost of these Pennsylvania improvements will be in the neighbourhood of £10,000,000 sterling. A comprehensive engineering and construction agreement for the mechanical and electrical engineering for the entire work has been made with Messrs. Westinghouse, Church, Kerr, and Co., who I think were also selected as engineers to the architects. The general direction of the whole work is assumed by President Cassatt, and the special supervision by Mr. Samuel Rea, fourth Vice-President, to whom all departmental bodies report. I wish it were possible for me to explain with some detail the extent and character of this undertaking, which in its tunnels and underground project is one of the greatest ever undertaken. To do so and to use even a part of the material given me when in New York, would be sufficient for an evening lecture. The photographs and plans will give some idea of its magnitude and importance. While an American firm has charge of the electrical side of the work, an English firm (Messrs. Pearson and Son) has the equally difficult task of driving these tunnels under the two rivers. The tubes will be driven by the shield method through the silt composing the river bottom, and with the aid of compressed air. Near the east shore of the North river it is expected that rock will be encountered. The general design of these tube tunnels is shown in the figure I produce on the screen. They are of heavy flanged cast iron sections, lined with concrete two feet in thickness. The substantial supports for the railway, consisting of steel screw-pile columns, are also shown, these supports being used in all silt formation. A novel provision, insuring safety in operation, will consist of the concrete side benches extending above the level of the car floor, and which will provide convenient walks as well as housing for the cable ways, &c. This combination of British and American engineering will undoubtedly bring about very satisfactory results.

The terminal station, some excellent photographs of which are presented, has, as you will see, a yard located below the street level, and the site occupies the four city blocks bounded by 9th Avenue, 7th Avenue, 33rd and 31st Streets, and includes the closing and occupation of 32nd Street on the surface from 7th to 9th Avenue; also a large section of the property between 9th and 10th Avenues on 32nd Street. The entire tract, measuring about 1,200,000 square feet, will be occupied by the terminal station yard at a level of about 45 feet below the surface. The excavation will involve the removal of some 2,000,000 cubic yards of material and the construction of massive retaining walls surrounding the excavation will require the use of some 50,000 cubic yards of concrete in the walls. The station tracts will be 21 in number, and the yard will include an area of about 20 acres under four blocks.

Not to be behindhand, the Pennsylvania's competitor, the New York Central, has undertaken a vast scheme of electrification. The necessity for this change arose from the serious inconvenience to the travelling public due to the use of steam locomotives in the four-track Park Avenue Tunnel, which extends from 56th

Street to 96th Street, a distance of about two miles. Furthermore, the City of New York desired the lowering of the tracks of the Grand Central Yard and terminal from 56th Street South to 42nd Street, so as to permit the restoration of the cross streets from 45th Street to 56th Street inclusive, which heretofore have been cut in two by the approaches to the terminal. This depression of the yard and terminal, with the consequent roofing in of the tracks by streets and viaducts, was not feasible with steam locomotive operation, and hence arose an additional necessity for using electricity as a motive power. The New York Central has also a large suburban traffic, as will be readily seen by the location of their lines on the map. The work of electrification is proceeding rapidly, and the new equipment includes electric locomotives, power house, turbo generators, surface condensors, and other auxiliary power station apparatus. The actual placing of these orders marks a profoundly important epoch in the application of electricity to the hauling of trains on the main line of one of the leading railways of the world. For the first time electric motors will compete in performances with steam in hauling heavy express trains of 500 tons and over at speeds exceeding 60 miles an hour. The change, I was told in New York, is expected to show marked economies in the electrified part of the railroad as a whole, and it will mean a great increase in the suburban traffic to Croton and White Plains, due to the purification of the tunnel, and the running of multiple unit trains every few minutes.

Speaking of this change from steam to electricity, it is necessary to mention the work completed about a year ago of electrifying the Manhattan Elevated Railway of New York's entire system of 40 miles. A comparison between the cost per car mile as worked by steam and electricity shows an economy of over 1d. per car mile, that is, it has been reduced from a trifle less than 6d. to 4¾d. per car mile. The working expenses decreased by 3½ per cent. last year as compared with 1903, whilst there was an increase of over 40 millions of passengers, and the net earning for the year advanced over £500,000.

The subject of New York transportation, like that of London, could easily form the topic of an entire paper of this kind, and so at the best I can merely mention these matters as we go along. To sum up, it may be said that the existing services are extending wherever possible, and the few remaining horse routes are being electrified where practicable. The Manhattan or "Elevated" proposes some additional linking up and extensions. Work on the subway already opened from the City Hall is in progress under Broadway to bring it down to the extreme end of New York, where there will be an additional extension under the river to Brooklyn. The Brooklyn extension is about 3·1 miles, having eight miles of single track, and the estimated cost is from £1,600,000 to £2,000,000. These works actually in hand, including two new bridges across the East River to Brooklyn, and other projected subway proposals, together with a new Manhattan subway belt line of 16 miles, sufficiently indicate rapid transit activities in New York.

NEW HARBOUR TUNNEL AT BOSTON.

While I have shown that New York has in course of construction several schemes for tunnels under both its rivers for taking passengers out of the city to Long Island or Brooklyn on the one side and New Jersey and Hoboken on the other, Boston has just opened to travel the first tunnel constructed by an American city to take the lines of its street car system under the water of an open harbour. It connects the mainland of the old Shawmut Peninsula, on which the business part of the Hub is built, with East Boston, still known familiarly by its Colonial name, Noddle Island, and is a mile and four-tenths long. The tubes contain two tracks equipped for the overhead trolley service employed on the surface lines of the Boston Elevated Railway, for at its suburban end the tunnel cars run on the regular street tracks. It is 24 feet from floor to roof, and its walls and arch are constructed entirely of concrete. It is the first tunnel in which that material alone is thus used. The cost has been about 3,000,000 dols., and it has taken about four and a-half years to complete the work. In Boston the opening of the tunnel to travel is regarded as important, mainly because it is a step in the progress of the New England metropolis toward the most comprehensive system of rapid transit that any American city has. It marks the completion of another of the great arteries of traffic which have been planned to take care of the expected growth of population, and is part of the comprehensive general scheme of the Boston Elevated Railway Company, which operates all the local street car lines, except a suburban line or two from the north. The tunnel runs from Maverick-square, East Boston, to

Scollay-square, in the city proper. The length of the harbour section is 2,700 feet and the depth of earth between the top of the tunnel and the harbour bed is about 20 feet. The minimum of earth over the bore after the harbour has been dredged to 40 feet depth will be about five feet. For further accommodation of traffic in the heart of the city there is now building a tunnel under Washington-street, the main artery of Boston business, that will be given over wholly to the use of elevated trains, which, when it is ready, will be withdrawn from the present Tremont-street subway, the pioneer construction of its kind in the United States, leaving that once more for the sole use of surface lines, for which it was originally built. The Rapid Transit line to Cambridge will also be underground in Boston and elevated on the other side of the Charles River; this tunnel will not be constructed until the completion of the new West Boston bridge, which, however, is well along towards completion.

THE NEW METROPOLITAN OF PARIS.

Returning to Paris and Berlin, it is necessary to say a few words about the Underground Electric Railway of the French metropolis. I have mentioned the original opposition of the municipality to underground railways on the ground that they would take the people out of Paris. After years of fruitless endeavour on the part of the travelling public, the French Government finally yielded, and consented to the line being built by the municipality as an independent railway not connected with the Paris terminal stations of the great railways. It is safe to assume that this attitude of the Paris municipality, together with the necessity of strongly fortifying Paris, has had much to do with the shaping of its locomotive systems on a circular rather than on a radiating plan; and this has had the effect of curtailing the creation around Paris of innumerable suburbs similar to those which have grown up around London under a system which was not subject to any such political or military restrictions. The Paris municipality's concern to isolate their system is shown by their attempt to adopt the narrow metre gauge, so as to lessen first cost, but also to render it impossible to connect the Metropolitan with the main lines, which the Government, however, altered to the standard gauge (4ft. 8½in.). Still, isolation has been completely effected by the adoption of a reduced cross-section for the tunnels, which will prevent the standard rolling stock of any of the main lines from passing through them, though not hindering the Metropolitan's carriages from travelling upon the main lines, should such an arrangement be hereafter desired. The scheme embodies a circular system of underground lines, numbering eight in all, in shallow tunnels worked by electricity, of a length of 38·86 miles, embracing, of course, the centre of Paris. The cost of construction is estimated at £12,000,000, which is being undertaken by the Municipal Works Committee. Begun in 1898, 1900 witnessed the opening of the first section, contemporaneously with the inauguration of the Central London. In 1903, the fifteen miles then opened carried 102,000,000 passengers. This, in spite of the shock of the serious accident, increased to 117,550,521 for the year ended December, 1904. To date, including Line 3 just open, some twenty miles are in operation. While the Paris and Central London systems present features in common, they differ in other respects. According to a report by Col. Yorke, of the Board of Trade, the Paris Metropolitain is constructed as close to the surface as possible, while the Central London is from 80 to 100 feet below the street level. The Metropolitain is in masonry, the Central London is in iron tube; the one has both up and down lines side by side in the same tunnel, the other has each track in a separate tube, which, you will recall, the King on the opening of the City and South London said he regarded as a "great advantage." Line 3 of the Paris Metropolitan Railway has just been opened, and runs from the north-west of the city, skirting the Gare St. Lazare station and passing the Opera to the Place Gambetta. As you will see from the map, it divides the irregular ellipse formed by the first two lines, serves the central boulevards of the city, and adds five miles to the fifteen miles of the system. The southern portion of Line 2 is partially in operation, and is almost completed, and only awaiting the two bridges over the Seine, one at Passy and the other close to the Pont de Bercy. With this completed, the Metropolitan of Paris will be very much like the London Inner Circle with the Central London and Brompton and Piccadilly crossing the circle east and west, while the north and south section to be constructed may find their counterparts in the Waterloo and Baker-street and Strand, Euston and Hampstead. The popularity of the Metropolitan is confirmed, in a negative way, by the

disastrous effect it has had on the receipts of that great monopoly, the Paris General Omnibus Company. The dividends of this company have disappeared, and the undertaking has been compelled to discontinue many of its lines and to sell a portion of its real estate property. Owing to the disorganisation of the omnibus company and the failure of several electric tramway companies, the traffic problem of Paris has assumed such a serious aspect, that the Municipal Council has been forced to take steps to alleviate the present condition of affairs, notwithstanding that the omnibus monopoly does not expire until 1910. The Traffic Committee, which was appointed to investigate the question, has drawn up a plan according to which the omnibus concession is to be renewed for 30 years after 1910, but on the condition that the company abolish the present horse omnibuses in operation, and replace them by mechanical traction. The proposal has been accepted by the Municipality, and has created a favourable impression in Paris. In London or New York the underground electrical railways, so far, have had very little effect on surface methods of transportation, which, however, does not seem to have been the case in the French metropolis.

Berlin's Elevated or Subway.

Beginning, as we have seen, with the Ringbahn or Circle Railway opened in 1877, and built with little or no regard for public convenience, the City of Berlin ten years later, or in 1888, opened the Stadtbahn, and the need of it was indicated by, for example, the statistics of 1900, which show that whilst the Ringbahn, with a much larger mileage, only carried 37 millions, the Stadtbahn carried 60·5 millions, and at the present time probably carries double that number. More interesting, perhaps, as showing the development of rapid transit in Berlin, is the new Electric Elevated and Underground Railway, seven miles in length, which passes over areas enclosed in the three municipalities of Berlin, Schoenesburg, and Charlottenburg. After overcoming many difficulties with these municipalities, and obtaining both the consent of the Government and the Sovereign, the work was put in hand in 1897, and in the beginning of 1902 the line was opened, the contractors guaranteeing a dividend of 4 per cent. The following year the owning company took over the working, and was able to pay a dividend of 3½ per cent., the traffic increasing 10 per cent. over 1902. Here also the municipalities had a finger in the pie, each of them securing a percentage of the annual receipts for the right of way. The line is mostly elevated, but some of it inclines into shallow subways. As an interesting combination of an elevated and subway railway, it is a striking example of engineering ingenuity. To Berlin, by the way, must be given the credit of inaugurating the first electric railway ever put into real service—the line of the Berlin Industrial Exhibition of 1879. But it is on the tramways and omnibuses that the Berliner relies for getting about. These in 1900 conveyed no less than 390 millions. It must be remembered that Berlin is peculiarly a tramway and omnibus city, coming into existence, as it were, during the tramway period, and hence its streets were more easily adapted to this mode of locomotion than the narrow tortuous ways of older cities. Few people realise in speaking of Berlin that not only has it had a higher average rate of growth in area than any other European city, but between 1861 and 1900 it shows an average annual increase in population of about 3½ per cent.; while the increase of the territory which now constitutes Greater New York during practically the same period (namely, between 1870 and 1900) has been 2 8-10ths per cent. per annum. During the same period (1861-1900) the average rate of increase of the population of London has been little less than 1½ per cent. In short, one might go on multiplying these radical differences in communities until all comparative studies of the question would be dismissed. The fact is that London is so unlike any other city in its growth and system of government, and its surroundings are so unique, that what applies to it does not apply (to any great extent) to other cities of the world.

The Building and Growth of London.

Before further considering the underground electric railways of London, I would call attention to four very interesting maps showing the stages of their growth. These maps were originally prepared by Mr. R. W. Perks, M.P., the chairman of the Metropolitan District Railway, and submitted to the Royal Commission on London Traffic by him in the form of large charts. I might mention that the Royal Commission and Mr. Perks kindly allowed me to make use of these maps in an article in "Traction and Transmission," a supplement of *Engineering*, and the slides that we have to-night are made from them, and are used at this meeting by the permission of the editor

of *Engineering*. The preparation of these maps has involved a great deal of labour, and the engineers who had charge of the work had to make elaborate investigations in the British Museum Library in order to ascertain from old maps the built-up portions of London 60 years ago. The idea was to show the built-up portion of the metropolis at four periods, namely, 1845, 1860, 1880, and 1900. To overcome the change in area during the period under consideration, the Administrative County of London, created in 1889, has been adopted, and is shown on each map by a light red colouring bounded by a full red line. Within this boundary the population and railway mileage has grown as follows:—

Year.	Population.	Miles of railway.
1845	1,949,277	29¾
1860	2,808,404	69¼
1880	3,830,297	215¼
1900	4,536,541	248½

The small increase in mileage between 1880 and 1900 will be remarked.

The figures, however, only represent the route mileage in each case. The track mileage, in which there has been a great increase (some of the railways having multiplied their tracks running into London five and six times in this period) is not shown. Had it been possible for the engineers who prepared these maps to have shown the increase of track mileage by the increased width of the line, an even more comprehensive idea would have been given of the railway extension in the county of London. I might say, however, that the length of railways for conveyance of passengers in Greater London in 1903, including the tubular lines in course of construction, was 630·3 miles; but of course the figures for the area covered by the administrative county of London are not nearly so great.

In these maps we see London as it appeared to our fathers in the early forties, with its population touching the 2,000,000 point, and its railways timidly approaching the central districts. In 1845, only one railway, the Great Western, was known by the same name as it is to-day and had the same terminus—Paddington. The London and South Western was known as the South Western Railway, and its terminus was Nine Elms. The South Eastern and Chatham and Dover entered London at Bricklayers' Arms Station as the Dover Railway, and took its exit as the Croydon Railway. From London-bridge Station ran a short railway to Greenwich, and from Fenchurch-street another short line to Blackwall. Shoreditch was the terminus of what was known as the Eastern Counties Railway and the Northern and Eastern Railway. Euston existed, but not as the terminus of the London and North Western Railway, as that system was known by the less pretentious title of the Birmingham Railway, with a small branch called the West London Railway, and a station at Addison-road. The number of railway stations in London 60 years ago was eight, namely, Euston, Paddington, Addison-road, Nine Elms, Bricklayers' Arms, London-bridge, Shoreditch, and Fenchurch-street. To-day there must be nearly 300. Think of London without Waterloo, King's-cross, Charing-cross, Liverpool-street, Victoria, Cannon-street, Baker-street, Marylebone, and a score of other less important centres of traffic! From the period immediately preceding the Great Exhibition at the Crystal Palace, we come to 1860, during which time Waterloo and King's-cross make their appearance, and the line mileage more than doubles, aggregating nearly seventy miles. Between 1860 and 1880 the railway mileage nearly quadrupled, and for the first time a network of lines appears in the centre of London. During this period the underground railways were born, the North London extension was built, and the stations of St. Pancras, Baker-street, Bishopsgate-street, Liverpool-street, Charing-cross, Victoria, and Cannon-street appear. Offshoots, and curves, and loops and circles, with here and there junctions, too complicated to be clearly shown on the maps, now completely cover what in 1845 and 1860 seemed an open area, and one is now plunged into the inextricable maze of London transportation. Another feature of the third map of the series is the growth of Greater London. It would be impossible to compare impartially the map of 1860 with the map of 1880, and declare that the railway companies entering London have not tried their best to meet the increasing requirements of London's growing population. A careful study of these two maps will make clear a good many questions which are so often dealt with in a superficial manner by those who imagine they can sponge out the network of railways and begin the work of reconstruction, whether on the map of 1845, or even on that of 1860. It is well to remember that the Royal Commission is dealing with even a more complicated map than the one of 1880, for since then tubular railways and elec-

tric tramways have appeared on the scene, which have come to stay. The growth between 1880 and 1900 has been, as far as the fourth map of the series goes, one of population rather than of railway route mileage. The actual mileage of track has undoubtedly increased, but the slight increase of thirty miles of route mileage shows what is very apparent, when glancing at the map of 1880, that the routes into, across, and around London had then been pretty well appropriated, and that the only possibility left for railway extension was underneath London. It is fair to assume that if surface railway extension had been possible during this period, it would have been made. The railway companies have been obliged to confine themselves to the increase in the number of tracks and of trains, and the enlargement of their carrying capacity, by larger carriages and longer platforms, and this shows that the limit of surface lines has been reached. Indeed, with the establishment of the Great Central's terminus at Marylebone, there seems no possible loopholes for new entrances to London, so completely is the inner circle surrounded by railways and public roads. For this reason, and not from lack of enterprise, has surface railway development been brought to a standstill, while modern enterprise and engineering have given their attention to the possibilities of the further developments of underground electrical railways.

London Essentially a Railway City.

London is essentially a railway, not a tramway city, and this assertion is made with a knowledge of the fact that the tramways in and around London conveyed in 1903, 361 millions of passengers, nearly as many as Berlin, which I have called a tramway city. There are in London and extra London 531 railway stations, and with the opening up of the new tubes, this number will be increased to upwards of 600. The length of the trunk lines, local lines, local joint lines and tubular lines (including those soon to be opened) in Greater London exceed 630 miles, this giving nearly a station to every mile of line. Of these stations 22 only may be regarded as termini —Moorgate-street, Mansion-house, Liverpool-street, Bank (Central London), Broad-street, Victoria, Angel (City and South London), Waterloo, London-bridge, Fenchurch-street, Bank (Waterloo and City), St. Paul's, Ludgate-hill, Snow-hill and Farringdon-street, Charing-cross (South Eastern and Chatham), Baker-street (Metropolitan), Cannon-street, Holborn-viaduct, Paddington and Bishop's-road, St. Pancras, Euston, Shoreditch, and Marylebone. Into these termini pour daily 4,252 suburban trains, and 445 other trains, making a total of 4,697. The same number must go out at night and during the day. The relief tubes and underground railways afford the streets is apparent when it is realised that the Central London trains of seven coaches can carry as many passengers as thirteen omnibuses. As 337 Central London trains run to the Bank every day, that is equivalent to 4,381 omnibuses. But the trunk lines, notably the Great Eastern, have even a greater capacity. The main difficulty in London, as all witnesses before the Royal Commission seemed to agree, was to get the passengers from the scattered termini to their work and business, but that will be remedied in a large measure by the new tubes, with their 52 new stations, and as many new connections with existing underground railways. Electrification of these local lines, and separation as far as possible from trunk line traffic will likewise increase the number of trains, the carrying capacity, and reduce expenses. Four-fifths of the half million of passengers brought into the central area of London up to 10.30 every day are conveyed by railways and one-fifth by tramways. Acting as distributors and feeders of the trunk lines the railways operating in London (undergronnd and surface) carry not less than 600,000,000 passengers per annum. Of this number the District, Metropolitan, North London, City and South London, and Central London last year carried 258,000,000 passengers. To this we must now add 14,000,000 for the Great Northern and City, making a total of 272,000,000. The new accommodation now in course of construction will provide facilities that will much more than duplicate these figures. The Great Northern, Piccadilly, and Brompton will provide a carrying capacity of 116,000,000, the Charing-cross and Hampstead 95,000,000, the Baker-street and Waterloo 116,000,000, and with another 100,000,000 for the electrified District and Metropolitan, and their improved extension and greater facility for passengers to exchange, will practically give greater facilities ranging from 400 to 450 millions additional passengers per annum. These estimates may seem rather large, and the whole system will have to be working harmoniously before the number of passengers will reach the full capacity; but judging by the history of existing undergrond railways, those now in course of construction

will be fully utilised. Mr. Cuningham, the General Manager of the Central London, told me the other day he was averaging over 150,000 passengers per day, and I should not be surprised to see the total for that railway reach 60,000,000 per annum, and this on a line of six miles. He is now running at a two minutes headway, but under certain conditions this could be reduced to a 1¾ headway. The headway in the New York Subway and tubular railways is one minute headway—so 1¾ would seem to be safe.

Here is a significant comparative statement of the traffic of the City and Sonth London :—

City and South London Railway.

Comparative Statement for Half-years ending June, 1891 *and* 1904.

	June, 1891.	June, 1904.
Length of Line	3 miles, 12 chains	6 miles, 9 chains
Train Mileage	174,435	589,401
Receipts	£19,688	£80,204
Working Expenses	£15,521–79 per cent.	£36,569–45·58 per cent.
Number of passengers carried	2,412,343	10,225,987
Or about	5,000,000 per annum	21,000,000 per annum
Dividend	Nil	2½ per annum.
Number of carriages	30	142
Number of locomotives	14	52

I am indebted for the above to the General Manager of the company, Mr. T. C. Jenkin, to whom the successful growth of the company's traffic is due. He has been associated with the undertaking from the opening, and by a progressive policy has, from a comparatively unimportant beginning, brought the business of the railway to its present position. The mileage of this railway has been doubled, but its receipts, and the number of passengers carried, have been more than quadrupled. The trains are now, during rush hours, running every 2½ minutes, and the daily number of trains is about six hundred. When the extension to Euston is completed, and the numerous connections with the other tubular railways are in operation, the traffic on this line will, in my opinion, reach at least 30,000,000 per annum. The 3½ miles of Great Northern and City Mr. Francis Fox informed me will reach 14,000,000, and when the extension to the Bank is finished, as it must be, this little tube will carry 20,000,000, the original estimate. Surely 30,000,000 is not too high for the City and South London when completed. The present line links up with the Brighton, and South-Eastern and Chatham, at London-bridge, the Baker-street and Waterloo at the Elephant, the Central London and the Waterloo and City at the Bank, and the Great Northern and City and Metropolitan Railways at Moorgate-street; and when the additional extension to King's-cross, St. Pancras, and Euston is completed (powers for which were obtained in 1903), it will link up, by means of subways, the stations of the Midland at St. Pancras and the Great Northern, and Great Northern and Strand at King's-cross, and by subways and lifts the platforms of the North-Western, and also the Hampstead and Charing-cross Railways at Euston.

The question will naturally be asked, will the ever-increasing traffic of London at once absorb all this new accommodation? The answer, I think, is that it will, as rapidly as the accommodation is ready for use. The American metropolis, with a capacity for carrying 1,200,000,000 passengers per annum, is preparing to carry 2,000,000,000 passengers, but experts in that city believe that in less than ten years from the completion of the present facilities the requirements will be 3,000,000,000. In both cities, what may be called the travelling habit, increases with the increase in the convenience and accommodation of the means of transit. The number of journeys per head of population has increased in a generation in London from 23 to 200 journeys, and in New York from 47 to over 400 journeys per head of population. But assuming that it remains the same in London, and then it will be seen that with 1,000,000 increase in population each decade, there will be an addition of 200,000,000 possible customers for the various means of locomotion. Thus, while these new tunnels have been in course of construction, 100,000,000 new customers have come into existence and are waiting to be carried.

Metropolitan and Metropolitan District Electrification.

The work of electrifying both the Metropolitan and Metropolitan District is proceeding very well, and both these systems have had "openings;" the former is now running an electric service between Baker-street and Uxbridge, and the latter electric trains between Mill Hill-park and Harrow. The line on the District from Hammersmith to the City will come next on the District, while Mr. Ellis, General Manager

of the Metropolitan, tells me that to avoid dislocation of traffic the electric trains will be introduced gradually. In short, these two railways will be completely transformed, and as a result the managers may look forward to a decided increase of passenger traffic. I shall append a few facts in relation to this work which will give some idea of the magnitude of the task of changing, for working by electricity, an ordinary gauge railway (constructed underground) carrying heavy passenger and goods traffic hauled by steam. The equipment in both instances will necessitate very considerable alterations in the permanent way, and as progress in the preparation of the road for laying cables, conductors, and insulators has to be made whilst the trains are running, and without causing interruption to the traffic, it will be seen that the difficulties to be contended with are very considerable, and of greater magnitude than would be the case in the construction of a new railway for working by electricity. The Metropolitan Company's generating station has been erected on land adjoining their engineering works at Neasden, London, N.W., and the work of installing the machinery is rapidly progressing. The site is admirably suited for the purpose, and its area sufficient to meet considerable extension of the power station. An abundant supply of water for all the requirements of the generating station has been found by sinking two artesian wells to a depth of over 400 feet. Advantage will be taken of the power to drive the machinery in the locomotive engineering works by electricity, thereby enhancing their manufacturing capacity, and electrical energy will also be available for lighting the whole of the company's works and station premises. The power station will be the most extensive in the kingdom owned by a single railway company; the main building covers an area of 3,570 square yards, or 318 feet long by 101 feet wide.

Transmission of Electric Power.

Another of these tremendous generating stations, very similar in construction, only larger, has been erected on the banks of the Thames at Chelsea, by the London Underground Electric Railways Company, which will furnish electrical power for the Metropolitan District Railway, and also for the new tubular railways under construction, of the London Underground Electric Railways Company. I visited this manufactory of power the other day, in company with one of my friend Mr. Thomas's artists, whose excellent drawings from the *Graphic* we reproduce on the screen. There I found on the banks of the River Thames, alongside of a muddy disused canal, in the prosaic neighbourhood of Lot's-road, Chelsea, a structure which fairly bristles with force and power. Its four stupendous chimneys, each towering 75 feet higher than the Monument of London, give some indication of the power required within the structure. The actual dimensions of the building itself are greater than those of St. Paul's Cathedral, namely 454 feet by 174 feet, and 140 feet in height. If cut in two and placed lengthwise, the Chelsea power-house would resemble an ocean steamer longer by 200 feet than those of the *Celtic* and *Cedric* type, but whereas the ships would have large spaces devoted to passengers, cargo, crew, dining saloons, and so forth, the structure I am describing is all a huge power-producing machine, probably the largest ever constructed at one time. Within and around this colossal building of steel and brick every inch of space is utilised, and when the fires are lighted and the machinery put into operation, the movement will be from start to finish automatic. It will be under human direction, but that is all.

The Chelsea Power Station will have to furnish power for several railways and convey it fifteen or twenty miles. This latter experiment (though it can hardly be called that) is being looked upon by railway men with considerable interest, as the question how far power may be economically conveyed by electricity is one of considerable importance. On this question Mr. Ralph D. Mershon, speaking before the American Institute of Electrical Engineers on ths subject of the maximum distance to which power can be economically transmitted, says:—

> "The elements which, in the broadest sense, limit the distance to which power can be economically transmitted are two; the cost of the power at the generating station, and the price which can be obtained for the delivered power. The difference between these two elements must cover the cost of transmission, the interest on the investment and the profit. The cost of transmission comprises the loss of power in transmission, the cost of operating and the cost of maintenance and repair."

Mr. Mershon further gives a curve showing the net profit for different distances of transmission assuming that power can be purchased or produced at £2 5s. 6d. per kilowatt, and sold at about £7 per kilowatt.

Taking the case that we wish to make 12 per cent. profit, we deduce from the curve that—

25,000 kilowatts	can	be	transmitted	110	miles.
50,000	,,	,,	,,	225	,,
100,000	,,	,,	,,	350	,,
200,000	,,	,,	,,	525	,,

One of the largest power transmission schemes is that of the Niagara Falls, which supplies electricity to New York 450 miles away. The amount of power used by the large plants in that city is approximately 175,000 kilowatts. Another large plant is that of the Washington Water Power Company, the transmission line of this system being 100 miles. A few of the large power distribution schemes in Great Britain are: the Cleveland and Durham County Electric Power Company, the Clyde Valley Electrical Power Company, Derbyshire and Notts Electric Power Company, South Wales Electrical Power Distribution Company, and Yorkshire Electric Power Company. The area which these six companies alone are to serve amounts to over 7,000 miles, with 19 power stations, most of which are now in course of construction. In comparison with these enterprises there would seem to be little doubt that the large power-houses of the Metropolitan and the London Underground Electric Railway will do the work required of them easily and efficiently. There are beside these two the splendidly equipped power-house of the London Central Railway, the one at Chiswick operating the London United Electric Tramways, the fine new one partially finished, I believe, at Greenwich for the London County Council's South London Tramways sytem, the new power-house of the North Metropolitan, and of course the Great Northern and City, the City and South London, and the one operating the Waterloo and City. The Great Western Railway Company is also building a large electric generating station at Park Royal; and while this railway has not committed itself to the electrification of its suburban railways, it will, as joint owners with the electrification of the Hammersmith and City, have to adopt electric traction on this part of the system. Under a new Act of Parliament railway companies have the right not only to contract for such power, but to produce it themselves, convey it along their own way-leaves, and sell it to manufacturers, mine owners, or others requiring power for any purposes whatever.

In the aggregate, all this work, with the traction improvements which they carry with them, exceeds in point of capital expended the similar work now in progress in New York under the supervision of an active and capable Rapid Transit Commission. Yet oddly enough London has a Royal Commission at this moment in session investigating with great care and deliberation with a view of determining what shall be done, a fact which once more indicates that London is like no other city.

THE WATERLOO AND CITY.

The second tubular railway in London was the Waterloo and City, a small tube running from Waterloo Railway Station under the main terminus of the London and South Western, and reached by inclined plane, to the Bank. This line was projected under the auspices of the South Western, for the purposes of relieving Waterloo Station of its suburban passengers, and discharging them in the City. It has been very successful, and passengers can exchange with the City and South London, the Central London, and the Great Northern and City, a most useful north and south connection. The Waterloo and City is also arranging for connection in the same way with the new Baker-street and Waterloo, which will enable passengers to pass direct from Waterloo Station to St. Pancras, King's-cross, Euston, Baker-street, Great Central and Paddington. This little tube, about a mile and a-half long, has been most successful; it not only pays very well as an investment, but last year four and a-half million fare passengers, and about one and a-half million season ticket holders, in all six million passengers, travelled by it.

THE "TWOPENNY TUBE."

The Central London Railway, or the "Twopenny Tube," as it has been popularly christened, was the third tube opened, and by reason of the fact that it is located under some of the most important arteries of London from Shepherd's Bush, being under Bayswater-road, Oxford-street, Holborn, Newgate-street, Cheapside, to the Bank, it is the best known of the London tubes. It is about six miles in length at present. The selection of this route was wise, because it runs through the very centre of London traffic, and converges at the Bank, where 774 vehicles pass each hour of the day. It passes under Oxford-street, which then could boast more traffic—running 550 vehicles an hour—than any other street in London; and it has a station at Oxford-circus, which ranks fourth in the list of points of greatest traffic, Piccadilly-circus,

Charing-cross and the Bank only exceeding it. The Central London has another station at the junction of Oxford-street and Tottenham-court-road, where 500 vehicles pass per hour. At the time this tube was projected, the thoroughfares under which it runs were found to be the routes of greatest traffic, and are probably so to-day. A more recent census of traffic shows, however, that what is called Piccadilly and Charing-cross route from Hammersmith to the City has a greater traffic now than the Oxford-street route had ten years ago. The fact that the Piccadilly route is even a better one, together with a four per cent. dividend, undoubtedly prompted the active competition of both the Central London and other companies for new lines along this route to the City.

It will not be amiss to refer here to the ventilation of the Central London tube. It must be admitted that tube ventilation is a very important matter, and one that is being seriously considered by engineers on both sides of the Atlantic. A well-known consulting engineer remarked to me the other day that the subject was so important and attracted him so much that if it were not for the financial necessity of conducting a general practice he would give it all up and devote his life to an attempt to solve this problem of tube ventilation. The Central London has done very much to improve the air of their tube. They have a large fan, which works at Shepherd's Bush, and draws the air out from the Bank through the tube the whole distance every night. This fan is sufficiently powerful to clear the air out twice over during the three hours when the traffic is stopped. In the day time, of course, there is a great deal of natural ventilation carried on by the motion of the trains. Mr. Granville C. Cuningham, General Manager of the Central London, told me in a talk I had with him the other day that he thought they had greatly overcome the difficulty of imperfect ventilation. The chemical observations made of the air in their tube show that it is by no means bad; there is, of course, the peculiar smell in the tunnel, which, though very difficult to account for, cannot in his opinion be attributed to bad air. The carbon dioxide that has been measured by the chemical observations is not large in the Central London tube as compared with other tubes, and the bacteriological observations give results that are even better than in the street. The chief objection, no doubt, is the smell in the tunnel, and this is said to be entirely due to the earth. It is to be remarked, however, that the smell is much less in the South London tube, but why this is so it is difficult to say. Mr. Cuningham is hopeful that as their experience increases the difficulty will be obviated. There might, for instance, be a system of horizontal tunnels adopted, running out from the middle part between the stations back to a distance, into a back yard, where a vertical shaft might be built, and a fan placed in that shaft running constantly, which would draw the air out of the tunnels while the trains were running. If such a plan were carried out during construction, it would, Mr. Cuningham thinks, form a very perfect system of ventilation. While I was in New York, this question of ventilation was raised in relation to the subway, but it seemed to be very well ventilated. Indeed, extensive tests as to the condition of the subway from a sanitary point of view, especially as to the purity of the air, were made by Professor Charles F. Chandler, the eminent scientist of Columbia College, at the request of the Health Department of the City of New York. According to this authority, the air in the subway is dry and pure, has not in any case suffered any serious loss of oxygen, and is for all practical purposes quite equal to the air of the streets as far as health is concerned as dependent upon the percentage of oxygen.

The constructors of the new tubes have given very careful attention to this matter of ventilation, as well as protection against fire. We have been assured both by Mr. Yerkes and Mr. Edgar Speyer that the additional cost involved in consequence of the Underground Electric Railways Company's desire to increase the comfort and safety of the travelling public has been large, namely, the use of concrete platforms, non-inflammable carriages, and all the latest and most expensive devices for the safety of passengers and the comfort of travelling. The cost, we have been told, has not been considered in obtaining the latest inventions for this purpose, and as far as human ingenuity could foresee, their cars, equipment, and the whole new system now being constructed are fireproof. For example, they have had the wood for portions of the cars treated by a special process to render it non-inflammable.

The precautionary measures, at the start, bear out the opinion of Mr. Cuningham, General Manager of the Central London, who, in his evidence before the Royal Commission, stated that the matter of vital importance in all tube railways was that the question of fire pro

tection should be attended to from the very first. It appears that on this tube they have had small fires in the tunnels and trains, but having appliances for dealing with them, they have been put out at once.

Attention has been turned of late to steel-framed and steel-plated cars, and it may be of interest to know that for the past eighteen months six cars of this style, built to the designs of Mr. Cuningham, have been running most satisfactorily on the system. The frame is steel; outside panelling thin steel plate; roof, sheet steel, lined with asbestos millboard. The advantages of this car are—(1) lightness and rigidity; it is 12 cwt. lighter than an ordinary car; (2) non-liability to fire; (3) greater internal space; owing to the thinness of the walls the car is 4½ inches wider inside than the others, the outside dimensions being the same. Similar precautions will be taken by the projectors of the new tubes.

Great Northern and City.

Returning to our list of tube railways, we come to the Great Northern and City, which was next opened after the Central London, in the early part of 1904. The line runs from Finsbury-park to a station at the junctions of Moorgate-street, Princes-street, and Lothbury. It is, of course, as yet in its infancy. While the traffic of this tube did not meet expectations when it was first opened, it now seems to have a satisfactory working arrangement with the Great Northern, and it is rapidly becoming a popular and important branch of the tubular system of London. More than a year ago I estimated that the traffic on this line when completed to the two points above mentioned would not fall far short of 20 millions. At first when it opened this figure seemed not likely to be reached, but as the Great Northern and City will carry this year 14 million passengers, it is by no means improbable. It is one of the most popular of all the tubes, because of its extra diameter, and the comfortable carriages, and the fact that it runs into the open, which gives it perfect ventilation. The power-house is most conveniently located at Poole-street, on the banks of the canal, where, it being easily accessible for coal and water, the cost of power has been very cheap. This tube is connected with all the other tubes operating in London, not physically, but by aid of passage ways. The traffic will further increase as the public realise the importance of this connection, and as tubular railways extend.

The New Tubular Railways.

The new tubular railways which the London Underground Electric Railways Company are building are rapidly nearing completion. The map from which the slide is made, and which shows all the tubular railways of London in operation and under construction, was prepared especially for this paper by Cook and Hammond, the well known lithographers (*see* p. 249). The Baker-street and Waterloo will be completed, Mr. Yerkes hopes, in the coming summer, the Great Northern and Brompton later in the year, and the Charing-cross and Hampstead early next year. In an enterprise of such magnitude there may of course be unavoidable delays in the delivery of machinery and the completion of work, but the company has its finances well in hand, and the capitalists behind the undertaking are capable of finishing the work and operating the lines in the most approved manner. To begin with, these tubular lines will give London more additional stations than the subway just completed will give New York. The stations will materially aid passenger transit, not only east and west but north and south. Thirty of them are located in the congested districts. Starting from Charing-cross, one will be able to go *viâ* Cranbourn-street, Holborn, Russell-square, to King's-cross, and thence *viâ* York-road, Caledonian-road, Holloway-road, Gillespie-road, to Finsbury-park, the terminus of the Great Northern and City. From the same starting point (Charing-cross) one may go north *viâ* Oxford-street, Goodge-street, Euston-road, to Euston Station, thence to Camden Town, where the passenger may branch off eastward to Highgate, westward to Hampstead, Golder's-green, and thence on to Edgware. Again, starting from the embankment at Charing-cross-bridge, the passenger may go *viâ* Trafalgar-square, Piccadilly-circus, Oxford-circus, Regent's-park, to Baker-street, and from thence *viâ* Lisson-grove, Edgware-road, to Paddington. Returning from Paddington to Piccadilly-circus, the new tubes will take him under the river to Waterloo Station, and thence on to the Elephant and Castle. From Holborn, Strand, Covent-garden, Charing-cross and Trafalgar-square, the new lines will run westward *viâ* Piccadilly-circus, Dover-street, Down-street, Hyde-park-corner, Knightsbridge, Brompton-road, South Kensington, Gloucester-road, Earl's-court, Baron's-court, to Hammersmith-broadway, which, in conjunction with Shepherd's-bush, comprise the two great western gates of modern London.

LONDON UNDERGROUND ELECTRIC RAILWAYS

Under the new schedule which will be put in force, the Underground Electric will, in conjunction with the District Railway, run from Hammersmith to Piccadilly in 20 minutes, and from Piccadilly to King's-cross in 10½ minutes, so that a passenger would be able to travel from Hammersmith to King's-cross in 30 minutes by the tube railway, at a cost of 2d., if they put on a uniform rate. From Charing-cross it would take 10 minutes to go to Euston, and the charge would be 2d.; and from Charing-cross to the Midland Station at Kentish Town the time would be 15 minutes. From Charing-cross to Highgate and Hampstead would be 19 minutes, so that if a person wanted to go to Hampstead from Westminster, he might get into a train at Westminster Station, change at Charing-cross, and be at Hampstead in 19 minutes from Charing-cross, with an addition, perhaps, of three minutes, from Westminster. At Charing-cross he could also change into the Baker-street and Waterloo trains, and be at the Elephant and Castle in eight minutes, or, travelling north, reach Baker-street in ten minutes, and Paddington station in 15 minutes. The time from Hammersmith to the Mansion House will be 26 minutes; from South Kensington to the Mansion House, on the main line, 16 minutes, and from Hammersmith to Bow, 39 minutes. When the deep level is built for fast trains, there will be no stops between Hammersmith and the City, excepting probably at South Kensington, Victoria, and Charing-cross.

This unrestricted method of exchange between these tube railways and the District will be a great advantage to the travelling public, and even greater if the Metropolitan Railway can be brought into the arrangement. The District is now laying down two more lines all the way from West Kensington into Hammersmith, where there will be terminal accommodation provided on the District Railway for the Brompton and Piccadilly line. When finished, which will be about a year from now, the Brompton and Piccadilly will start from a terminal dock in Hammersmith Station and run all the way to Finsbury-park. There will then be four lines instead of two on the District Railway from West Kensington to Hammersmith.

By the aid of the electrified District Railway, passengers will be able to go from Hammersmith straight away through to the City. Of almost equal importance to the new stations will be the connections with existing lines that these tubes will be able to make. Perhaps not at once, but with here and there additional connecting links, there will be formed a complete system. For example, the new tubes will cross the Central London at three points—Holborn, Tottenham-court-road, and Oxford-circus. They join the District at Charing-cross and Embankment, and the City and South London at Elephant and Castle. Including the District, which connects with Victoria, Cannon-street, London-bridge, and Liverpool-street Stations, the Underground Electric will connect with all the important passenger stations—Paddington, Marylebone, Baker-street, Euston, St. Pancras, King's-cross, Charing-cross, and Waterloo. These trunk line stations annually pour into London over 300,000,000 passengers, the greater portion of which number must be carried to the central districts. The Underground Electric enters important districts, as the above list of stations shows, where the traffic up to the present time has been almost exclusively worked by omnibuses.

The question has been asked, and not without reason, will these new tubular railways pay? Judging from what is now known of the electrical railways in operation I think they will. The twenty miles of underground and elevated railways in New York which have been opened but a few months are carrying 400,000 passengers daily, or over 150,000,000 annually. The Metropolitan of Paris, with its 15 miles, is carrying 120,000,000 annually. The total will be largely increased by its five additional miles just opened. The six miles of the Central London may exceed 50,000,000 passengers this year, while the other three tubes will indicate increased traffic which will advance further as connections improve. Based on the earnings of the Central London and on a passenger traffic of 55,000,000, the Baker-street and Waterloo should earn £230,000. The Great Northern, Piccadilly and Brompton, with a passenger traffic of 85,000,000, should earn £358,000, while the earnings of the Charing-cross, Euston and Hampstead line, with its 75,000,000 passengers per annum, should be in the neighbourhood of £316,000. With a common power-house the working expenses should be much less than 50 per cent. of the earnings, the Central London being just over 49 per cent. With the growth of London they will undoubtedly become profitable investments.

VIBRATION AND EFFECT OF TUBULAR RAILWAYS ON BUILDINGS.

Now and then we hear a sensational story that the tubes have caused cracks in some important public building, and when the Central London was started there was more or less complaint in relation to vibration, but this has been obviated by the removal of the heavy engines, and the use of smaller motors attached to the cars. I have given you an instance in Chicago, where the whole business part of the City had been tunneled, the top of the tunnel being only 24 feet from the surface of the street, without, even, in a great many cases, the knowledge of the occupants of the mighty sky-scrapers. As a rule these alarms have proved both foolish and false. One of the more recent has been with regard to St. Paul's Cathedral, the foundations of which were said to be sinking as a natural consequence of the borings going on for the tubular railways and the pumping which accompanies the work of driving the various tunnels constructed in its immediate vicinity, and others that were in progress. Then ominous fissures have been discovered in the fabric; the moisture in the gravel bed of London was said to have been drawn off by pumping for the various tunnels; lower water courses have been formed in every direction in which the tubes penetrate; engineers have failed in their attempts to hermetically seal the tubes to the clay, &c. As to the cracks in St. Paul's, these were shown on investigation to have been done as far back as 1835, during the construction of a deep drain. It is true these old cracks have been slightly reopened, but the construction of the tubular railways according to the best authorities cannot be blamed in the matter. With regard to the alleged result of pumping, another authority says it is most unusual to resort to pumping to any great extent. There are miles of tubes now in course of construction where he states not one drop of water has been.

To show how effectively tube and station construction underground can go on without danger to buildings above, I might instance the case of the church of St. Mary Woolnoth, situated at the corner of Lombard and King William-streets. Underneath this church, as you are aware, is the Bank Station of the City and South London Railway, in connection with their City extension to Moorgate-street. Talking with Mr. Basil Mott and Mr. David Hay who, with Sir Benjamin Baker, were the engineers of this extension to the City from the Borough, these gentlemen gave me an interesting account of how the City and South London put a new foundation to this—one of the oldest of London's churches. It was originally the intention of the company to acquire and pull down the church, but as some outcry was raised about demolishing what was considered a remarkable example of church architecture, the company agreed to leave it standing, and construct the station underneath. This entailed the removal of the whole of the old foundation, and the substitution of a steel table standing on massive legs to support the fabric, before the station works could be proceeded with. When this had been accomplished, a 72 feet long, 24 feet wide, and 100 feet deep shaft for five passenger lifts was sunk immediately below the building, with adjoining corridors at the bottom, and passages leading to the station platforms. A booking-hall was constructed under the street, from which a passage communicating with the waiting-hall had to be driven directly below the church tower. Mr. David Hay has been kind enough lo allow me the use of some slides showing how this difficult task was satisfactorily accomplished.

Slide 1 shows the plan of the station at booking-hall level, about 10 or 12 feet below the street. The lift shaft is seen extending right across the church, the oval booking-hall and passage below the tower communicating with the waiting-hall. The five lifts are together capable of raising 450 passengers at a time.

The second Slide shows a section through the centre of the shaft with the church overhead. You will notice the girders supporting the walls, roof, and columns and floor of the church—a weight of something like 1,500 tons. The elevators are also shown, some at top and bottom, and one halfway up. The tubes are shown under the street, also the staircases and passages to platforms, which are situated in large tubes a little further towards the river.

Slide 3 is a section through the booking-hall and lift shaft, and adjoining corridors for entrance to, and exit from, the lifts at the bottom. The lift machinery is also shown at the bottom of the shaft.

Slide 4 is a plan at bottom of shaft. It shows the corridors and passages leading to and from platforms, and also the electric lift machinery.

Turning to other parts of the railway, Slide 5 shows a view of a tube tunnel (30 feet internal diameter) in course of construction.

Tunnels of this kind are made at the Clapham-common and Islington termini. They are large enough for two lines of rails and an island platform. The engineer for this scheme, as opened in 1890, was the late Mr. J. H. Greathead, and it is needless to say what a debt of gratitude London owes to this gentleman in being the first to introduce in a really practical way a system which, to say the least, is one solution of the problem of London traffic. Mr. Charles Grey Mott has been chairman of the company since its inception, and it is not too much to say that to his ability, energy, and perseverance London owes a debt of gratitude for the introduction and development of electric traction on underground railways.

General Conclusions.

It has only been possible to review in this paper the progress of electrical street railway work in London, New York, Paris, Chicago, Berlin, and Boston. From the very inadequate manner in which I have touched upon these great industrial works, you will be able to gather that much is going on in this direction, and that the end of the work can only be when these cities cease to grow, or when the industrial centralisation of our own times changes to the industrial distribution which may come with the lessening in cost of power distribution. The extension of such enormous distribution of power as, for example, the Niagara electric plant, and the various power plants in course of construction in the United Kingdom, must distribute factories and shops over a wider area. Steam undoubtedly concentrated industry, and built up the large "coketowns" of the present day, while it is more than possible that the use of electric current generated in stupendous power plant such as those I have shown are now actually in operation, and in course of construction in London, New York, and other centres of industrial energy, will result in a migration of factories and workshops further afield. But some will say, possibly persons in this very audience, what right have these large cities thus to grow and increasingly demand these stupendously expensive machinery for getting about? I am perfectly aware, as most of you are, that there are some philosophers who contend that our modern cities should not require this rapid transit—that the great cities of the East, from Babylon to Pekin, appear to have grown up without the necessity of rapid transit. Indeed these people are enquiring whether, as in the case of London, the limits of its usefulness as a system of homes and trade settlements have not been reached. It is not my intention to go into the question of the centralisation of industry, nor the centralisation of amusements, nor of official, commercial, and artistic life. There is no doubt that the evidence taken before the Royal Commission on London Traffic has revealed a state of affairs most unprofitable to the railways, and most disastrous to certain sections of Greater London. We have seen this winter something of the evils of too cheap transportation in the sad conditions of affairs at West Ham, Tottenham, and other places in north-eastern London. How far this system of cheap fares is justifiable, and whether they should be abolished, I have no doubt we shall hear when the Commission reports; but I am clearly of the opinion that it will be far better for factories to move out of London, where industries could be carried on under more satisfactory conditions, than for the State to compel the railways to adopt such a schedule of fares as, for example, those of the Great Eastern, for the so-called benefit of the working classes. An admirable article by Mr. T. C. Elder on "The Movement of London," published in *Traction and Transmission*, contains this passage, which it is well to remember in discussing the future needs of London in rapid transit:—

> "There are a great many people in the metropolis who could probably be more profitably employed, and for whom there is more comfortable accommodation, elsewhere. Without asking where they come from the Government appoints a Commission to invent some means of enabling them to settle down at their ease, and to invite their friends and relatives to join them. So long as the machinery of State is set in motion to assist manufacturers in retaining their present position in the metropolis, so long will they remain."

This is a phase of the rapid transit problem that we do not hear much about from those constantly pleading for more facilities and cheaper fares, but it may indicate that if there is no finality to profitable rapid transit, there may be a finality to the demand for additional cheap facilities which robs one class of the community to subsidise another. It has been claimed by some, and not altogether without reason, that the virtual purpose of the Royal Commission on London Traffic is merely to seek some means of providing rapid transit for those who cannot afford to pay for it. If, instead of

accepting the fact as an indisputable proof that "such people are living and working under uneconomic conditions," the same amount of energy on the part of those in high authority was devoted to inquiring what would have for its results "the encouragement of that decentralisation which would appear to afford the only permanent amelioration of the conditions of town life," the outlook would be much more hopeful.

While the subject of this paper has been the Underground Electrical Railways of London and other large cities, I am in no sense an advocate of this system of transportation, and no other, for London. A complete survey of the subject involves the consideration of (1) street vehicles, (2) surface railways or tramways, (3) overhead railways, (4) shallow underground railways, (5) deep level railways, (6) deep level or tube railways for freight, (7) electrification of steam railways, (8) straightening and widening of streets and bridges, (9) construction of new thoroughfares and bridges, (10) improvement of regulation of traffic. All these methods have their place in the solution of the traffic problems of such a city as London. London has outgrown the period when the improvement of any one of these methods of dealing with the traffic can make a perceptible difference. As a matter of fact, and we all know it very well, while the Royal Commission has been taking evidence on all these points, and many others, such as suspended railways, mighty avenues running to all points of the compass, double deck streets, and circular roads around the whole metropolitan area, those in charge of the several existing methods of transportation have been industriously studying how they can improve, extend, and quicken their systems of transit. One witness, when asked by the Commission for his solution, answered very promptly, "London requires all the existing facilities." The omnibus, the tramways, the tubes, and the undergrounds all do their share in the working of such a mighty body as London. The important thing is to get these all to work in harmony. If the Royal Commission can suggest a plan to do this it will have amply justified its appointment and the time it has taken to reach its conclusions. The unification of these several facilities by some common ownership or consolidation of management must in my opinion be precedent to any really satisfactory or lasting solution of the problem. The hope for such a settlement lies in the joint use of tracks, of stations, of passenger exchange from one line to the other when physical connection is impossible, and, even more than all else, in electrification, with the important economies that must come in the joint use of power. It is the large electrical power-houses, which we have seen are going up in so many directions in and around London, that will bring these interests together. It is nice to have your own exclusive power-house, but when it is found that your competitor is obtaining his power cheaper because it is being shared by a number of other enterprises, there will be a consolidation of interests on the cohesive basis of mutual profit, and from that the step is short to harmonious management. In a country like England, where the interests of the public are so carefully guarded, there will be no possibility of monopoly, and the travelling public will receive a full share of the benefits of electrification in the reduction of the cost of operation which is sure to follow.

As to the merits or demerits of different methods of dealing with transportation, there is little to be said when dealing with a city like London, which requires them all, and where (with the exception of freight tunnels) all methods are showing commendable activity. London cannot afford to put all her eggs in one basket. Note how invaluable the tubes were during the recent foggy days; in the spring and summer, what a boon to many are the upper decks of the tramways. For short distances there are omnibuses, soon, let us hope, to be converted into motor road cars. For long distances there are, or will soon be as I have shown, to a very much greater extent, the undergrounds and electrified street railways. And when each of these various methods of improving London is striving with considerable energy to increase its capacity, to improve its speed, and to make passengers more comfortable, or even to reduce or unify fares, it is only just that such activities should be recognised, even if it should be regarded as impolitic to add a word of praise. The battle for the London tubes seems to have ceased since the appointment of the Commission, but the Bills deposited for the coming Session indicate that capital is still forthcoming to link up and extend London's underground electric railways. The discussion of these new proposals involves controversial questions upon which it is not my purpose to enter.

Turning, therefore, to what is actually being done to relieve London, what do we find? The large extension of tubes and electrification of

existing underground railways and connections involving the expenditure of £25,000,000, perhaps £30,000,000 sterling; the extension, linking up and electrification of tramways by the London County Council in South London and similar work by the North Metropolitan in North London; the important subway connection for these two systems of surface railways—an enterprise in itself—that in a smaller city would attract a world-wide attention; the continued extensions of the London United Tramways in the western part of London. The Great Eastern and London and South Western, to say nothing of the three important northern railways, London and North Western, Great Northern, and Midland, are doing much that is wise and helpful for the suburban traffic. Independent of railway work the bridge building projects, the straightening and widening of thoroughfares such as the Strand and Fleet-street, and Piccadilly improvement, would form the subject of a paper as formidable as the one I am about concluding. Here we have the same idea in view—the relief of congested London. It is being carried out by the London County Council with great skill, and must prove permanently beneficial. Added to this and on the outer rim of the metropolis there are the steam lines which cut a far greater figure in what may be termed the street railway work of London than is the case with similar railways in other large modern towns. The work of electrification, as we have seen, has started: the Metropolitan and Metropolitan District have actually inaugurated electric trains on suburban lines; the London Brighton and South Coast have decided to electrify from Battersea to Peckham Rye, while the Great Western Railway proposes an extension from Ealing which will tap both their High Wycombe and Windsor lines, and bring passengers down to a new station at Shepherd's Bush, thus relieving both Paddington and Bishop's-road Stations. The completion of the Great Western and Great Central Joint line will add another new track to the many trunk lines entering London, and build up another important and almost untouched section of surrounding country. With the development of the single phase motor, which has made great headway within the last two years, there is no longer any necessity for a third rail, for a single small high-tension overhead conductor may be safely used instead. This will greatly simplify and cheapen the construction of electric railways, and enable the great railways which have in the past done so much to provide cheap and even rapid transportation into the surrounding districts of London, to retain their present share and to increase largely the speed and facilities for handling passengers. In this category we find the North London, the London Tilbury and Southend Joint, the East London Joint, the London Brighton and South Coast, and London and South Western Joint, and sundry other extensions and connections. These steam railways, after breaking through say a twenty mile radius around London, cross and recross each other in such a complex network of lines that they all become hopelessly merged into one system, handling together hundreds of millions of passengers annually, yet separately they are so unobtrusive that the traffic is not recorded but merged in that of the several railways operating them. This tangle of lines, with several hundred stations all within the limits of the county of London, is at the present moment facing the question of electrification. In ten years these lines, in my opinion, will be electrified and operated on some harmonious system that will be fair to all and immeasurably better for the travelling public. It is unfair to say that the gentlemen controlling these properties are unenterprising because they have not already changed from steam to electricity. They know well enough that electricity on new and independent lines and on tramways works better and quicker, is cheaper, and more comfortable for the passengers than steam, but they are not satisfied that these smaller units of their great systems can be worked with one system of propulsion, and their larger trunk lines, with heavy freight trains, by another. Whatever, therefore, is done in this direction by these railways, must be done with two distinct things in view, namely, the installation must first be capable of operation with the existing steam system outside the London radius, and secondly, it must be capable of extension to that system, as further improvements make it practicable and economical so to extend the electrification. Let the experts engaged in these modern problems of locomotion once satisfy the railway managers on these two points, and the steam locomotive will disappear, not in a night, but by degrees, first, as we hope will soon be the case on the Inner Circle, then on these cross and joint lines, and finally on the trunk lines. The theatre of these experiments is now clearly defined, and the future extension of operations of this sort will

in a large measure depend upon the outcome of the electrifications in progress of installation.

Another movement working for the relief of the streets, and one which will be almost imperceptible at first is the change of the omnibus and car companies from horse to motors. It will take time to effect these changes as it will to change the large waggons and delivery carts in the same way, but it is a change that all authorities on the subject admit is sure to come, and when it does will have its influence.

In the aggregate the work going forward at the present time is enormous, and as we have seen exceeds in mileage and capital investment the great works which I have mentioned in Paris, New York, and Chicago, which are the only cities that are doing anything at all comparable with that which is being done in London. This is no reflection on the enterprise of the other cities, some of which like Boston and Berlin are doing interesting and important work. As a rule, however, most of the modern towns of the world are fairly well supplied with rapid transit, and in these cities the problem does not present anything like the difficulties and obstacles which have to be overcome when dealing with this question in the greatest of all modern centres of population—London.

DISCUSSION.

The CHAIRMAN said he had lived the greater part of his life in London, and he thought there were few questions of greater importance to Londoners than the increase of locomotive facilities. He had had almost unique opportunities of seeing the marvellous augmentation to the population of inner and greater London. Thirty-seven or thirty-eight years years ago he was elected M.P. for the County of Middlesex, which comprised the whole of the outer area north of the Thames which was outside inner London; and he had seen with his own eyes, decade after decade, the extraordinary development of population in a district which, thirty years ago, was an almost purely rural district. He believed the population he represented when he first went into Parliament was about 200,000; and he was quite confident that it was now considerably over one million. There was the peculiar phenomenon about this great increase of population that, so far as he knew, great aggregations of population had about entirely been caused by an important industry being created in a locality, which attracted large numbers of men and women seeking employment. The peculiarity of the increase of population in the suburban parts of London was that a very considerable portion of the people were divorced from their work; they had to yield to certain irresistible economic forces. There was a process going on in London by which, year after year, more and more houses in the inner circle were being demolished, or converted into places of business and factories. There was, in one sense, a centrifugal movement going on in the centre of London, by which the population were forced more and more into the outer parts of London. But, inasmuch as a large proportion of the people so forced out still had their occupation in London, there was the reverse movement, the centripetal movement, by which every year a large proportion of the outer population of London were forced into London daily in order to pursue their avocations, and obtain their livelihood; and it was that condition which, he thought, presented the great difficulty of locomotion in London. It was clear to all who knew London, that although there might be no difficulty in largely increasing the mechanical means of locomotion in Greater London, yet so soon as one dealt with inner London, it was almost impossible, under existing conditions, largely to increase surface locomotion. London streets were not built in accordance with any great plan; they were the streets of a number of original hamlets or villages which became absorbed in London; and therefore it was almost impossible to develop any system of electric tramways such as other great capitals, built on a different system, had supplied themselves with. He remembered many years ago discussing the question with Sir Edward Henderson, who was, at that time the Chief Commissioner of Police; and that gentleman summed up the situation very clearly in a sentence, when he said:—"The streets of London were intended for a traffic of 500,000 people, and I have to manage five millions." He thought everyone would agree that if it were not for the marvellous tact, patience, and skill shown by the Metropolitan Police in the management of traffic in crowded streets, great difficulty would be found, at certain times of the year, in getting about at all. That being so, it was clear that if an increased demand for locomotion arose, and if it could not be met by an increase of mechanical appliances on the surface of the earth, recourse must be had to underground railways, which must be of such a character as not to interfere with the comfort or stability of the houses already erected in London. The question of greatest interest to the audience was, would electric railways in London be able to meet that particular and ever-increasing want? If it were possible to solve the difficult problem of improved locomotion in London by underground electric railways, he did not hesitate to say that those who achieved the object would confer an enormous benefit upon London generally. Mr. Porter had given evidence in his paper of the possession of a thorough appreciation of the requirements of great cities in respect to improved locomotion.

MR. PHILIP DAWSON thought that everyone present would agree with him in saying that thanks were due

to the author for the excellent way in which he had brought forward a most difficult subject. Mr. Porter had pointed out that whilst a good deal was heard of the work which was going on in such cities as New York, Boston, and Paris, in regard to additional rapid transit facilities, and whilst very often the work which was being carried on in London was condemned, as a matter of fact at the present moment there were greater rapid transit facilities being constructed and completed in London than in any other city in the world. He congratulated the author on the fact that although he was originally an Englishman, he was one of those people who were greatly appreciated in the United States. Personally, he took a peculiar interest in the subject under discussion, as it had been his lot for several years past to investigate the question of the possibility of introducing electric traction on main line railways; and there were some points in that connection with which he joined issue with the author. Mr. Porter had suggested that large power stations might be constructed which would supply energy to a great many railway companies, and that that would facilitate the electrification of railways. He could not agree with him on that point, because on the railway whose requirements he had been studying for the last two years, from 40,000 to 50,000 kilowatts, or, roughly speaking, 75,000 horse-power, would be required for handling their suburban traffic alone. From the result of the examination he had made it was his opinion that once an amount of 20,000 or 30,000 horse-power was reached, no saving could be made in regard to capital expenditure or operating expenses; and naturally, as the author stated, a railway company would prefer to have its own power station rather than purchase power elsewhere, particularly when the fact was considered that railway companies were in a particularly favourable position to produce electricity cheaply and economically. There was one point made by the author with which he thoroughly agreed, and which he wished to emphasise, namely, the absolute necessity of doing away with the third rail. In the investigations which he had made, he reluctantly came to the conclusion, although he had sometimes been called an electrical enthusiast, that if the third rail were a necessity to the electrification of main line railways, electrification could never take place. But fortunately the requirements of railways had brought forth a solution. As the author stated, the single-phase system enabled engineers to use currents at very high pressures, and overhead wires, and would thus dispense with the third rail, which was not only dangerous to the travelling public as well as to the company's officials, but was also a source of greatly increased expenditure in regard to maintenance. That system was to be tried on the Brighton Railway Company on the first section between Victoria and London-bridge, and he trusted that perhaps a year hence the line would be successfully operating, and that he might be able to show those present over it.

Mr. E. L. Walford said that those who travelled on the Great Northern and City Railway must have noticed how superior the ventilation of that railway was compared to either the Central London or the City and South London, and he thought the reason of it was that there was an open-air station at Drayton-park. He wished to ask whether it would be practical for the other tube railways to have an open-air station at the highest point of the tube, and so ventilate the line. It seemed to him a very great pity that in the general electrification of railways which was now proceeding nothing was being done to electrify the East London Railway, which was the most important link of the systems north and south of the Thames. He thought the electrification of that line might easily be managed by the different companies who at present leased it guaranteeing the interest on the capital necessary to electrify it.

Mr. J. F. Loree said that he was unable to add to the details the author had given of what was being done in the States on the rapid transit question, but he could assure the members that they were all troubled with the magnitude of the problems in front of them. As he listened to Mr. Dawson the question ran through his mind whether a decided advantage was not obtained in a community of interests in generating stations by the support they gave each other in emergencies, and by a more economical load line resulting. One of the great difficulties connected with the use of electric power was that facilities always had to be provided for generating the maximum amount of power to be used for only a short period of time. It happened that during the two or three years when he was president of the Baltimore and Ohio Railway—which was the first railway in America to use electric power for traction purposes—in the effort to get a more economical load line large amounts of power were supplied to the local traction lines in Baltimore, and to the manufacturing establishments throughout the city. Certainly if that power-house could have furnished power to other railway companies, and they had a joint interest, it would have been a very much more economical undertaking. It might interest those present to know that when Baltimore was overtaken with a great calamity in February last year, and some 132 acres of buildings, comprising the principal business portion of the city, were burned, the electric lighting stations and power-house of the local traction companies were destroyed, and in the emergency the generating plant of the Baltimore and Ohio Railway had not only to maintain the railway traffic through its tunnel, but to light the town and furnish power for local traction purposes.

Mr. Francis Fox said the question had been asked whether science, engineering, and capital could provide a solution to the traffic problem. On behalf of the engineering profession, he could give a distinct

answer in the affirmative. If the necessary capital and powers were supplied, and they were kept free from the absurd restrictions which were often placed upon them by borough councils and other bodies, he believed the great traffic problem of London could be successfully solved. The question of the increase in the number of passengers aud the number of journeys per head, was a matter of education. When he was last in New York, he had to investigate the number of journeys that were made per head of the population in that and other great cities; he also did the same work in London; and he found that while in New York 500 journeys per annum were made per head of the population, in England it was only something like 1-10th of that figure. It was stated in an old book that, at a certain period of the world's history, knowledge would be increased, and many would run to and fro; and he thought that point had been reached. He believed English people were learning to run to and fro, but he hoped they would not reach the point arrived at in America, where people seemed to be imbued with the idea that they would be much happier anywhere else than where they were. The first object an American seemed to wish to attain was to get into a tramcar and go into the country or to another part of the city, and there jump into another car and come back again. He did not think that conduced to the welfare and stability of a nation; and although Englishmen had many things to learn from their American cousins he hoped that they would not copy the terrible rush and haste that was seen in Chicago and New York. The last speaker had referred to the tunnel at Baltimore. He was very much struck when he visited that city with the excellent arrangement made for carrying the fast trains through the tunnel and letting them go on their journey without even stopping, the electric locomotive running ahead into a siding and allowing the train to pass. He believed the arrangement was called "fly shunting." He quite endorsed Mr. Dawson's remarks with regard to the third rail. It was an absolute impossibility to have a third rail on a ballasted road. A third rail could be used on a overhead railway, where it could be fixed to the floor of the structure, or it could be used in a tube with a comparatively low voltage, but on a ballasted road, where men were continually packing the sleepers, it was a matter of absolute impossibility to use it, and it would prove a grave danger, as was illustrated by the numerous accidents which had taken place in the North, where platelayers with shovels in their hands had had the shovels destroyed by their getting in contact with the current. The sooner the third rail was abolished from a ballasted road the better it would be for the whole of the travelling public. The question of high tension was a very serious one. Anyone who had seen a high tension wire break, and hang dangling down "fizzling," knew it was not a nice thing to see, and it was certainly a disagreeable thing to come in contact with. That was a difficulty which would have somehow or other to be solved. With regard to the increase of the traffic on London underground lines, it was an ill fog that did not do somebody benefit. He thought the recent fogs had educated the public to a very great extent in regard to the enormous benefit of tube railways in more ways than one. The temperature of the tubes was practically the same summer and winter; the streets of London might be blackened with a dense fog, while down in a tube it was perfectly clear. It was exactly the same in the Mersey tunnel; while there was a dense fog on the Mersey it was perfectly clear below. The consequence was that traffic could proceed on the tubes without any difficulty; and fogs were therefore educating people into the beneficial use of underground railways, and, to that extent, would clear the streets of the congested traffic from which London at present suffered so much.

Mr. T. C. Jenkin (Manager of the City and South London Railway) apologised for the absence of the chairman of his company, who regretted his inability to attend the meeting. The City and South London was the pioneer electric railway of London; and the late Mr. Greathead and the Chairman of the City and South London Company were the pioneers of electric traction in London. It was a great compliment to his railway that most of the subsequent lines which had been built and were now in operation were due to the success of his own undertaking. No difficulty was experienced with the third rail on their railway. The railway had been in operation for fifteen years, and no accident of any kind had happened; while there was no danger whatever if the men happened to step on the rail. With regard to the question of atmosphere and ventilation, a most eminent engineer inspected their line, and reported that the ventilation was perfect, in fact he referred to it as the Riviera.

Colonel Allan Cunningham said the question of ventilation very closely touched the question of the personal comfort of the passengers. No doubt the ventilation of the Metropolitan Railway would be good as soon as it was electrified, but it was different in the case of the small tubes. The "twopenny tube" was so small that its ventilation left a great deal to be desired, and he would like to ask the author what was the condition of the atmosphere in the 32 miles of tunnels in Chicago.

Mr. Porter stated that the tunnels in Chicago were only used for freight purposes, and the ventilation was not at all bad. There were only a few people down in the tunnel, which had an opening right on to the Lake front.

Colonel Allan Cunningham doubted whether such a tunnel would be useful for passenger traffic with only one such opening. As probably one of the

oldest persons present, he had seen a vast change come over the conditions of London traffic. Fifty years ago there were very few omnibuses; the shortest journey on an omnibus cost 6d., and the population was then only three millions. Every increase in the facility of travelling had been a great help at the time—too much at the time perhaps—but the increased facilities had attracted more customers to the lines, and more residents to the places which the lines served. Those conditions, and the natural increase of population, had invariably after a time overtaken the increased facilities, so that five or ten years afterwards the congestion on various lines had been just as great as ever. He apprehended that though the new railways proposed would be for a time a very great convenience they would follow the rule of all previous history, and in the course of some twenty years the congestion of traffic would be as bad as ever. The very great convenience of pouring crowds of people into a large city at their business hours was a thing to be sought after, but it was attended with one serious inconvenience. The time did not seem to be far distant when the streets would not be sufficient for the great number of foot passengers in them. That happened with serious results on the occasion of any great public spectacle. Within the last fifty years the crowds at public spectacles had increased to enormous proportions. The suburban railways offered such facilities for throwing enormous crowds into the city to see any big public spectacle, that the crowds were now getting more and more dangerous, and that was a difficulty which would have to be met somehow.

Mr. NORMAN MACDONALD said that the overhead wire on the Brighton railway, which was to carry 6,000 volts, to which Mr. Francis Fox had referred, would practically be a continuous girder or bridge, and therefore any chance of a catastrophe occurring through it being broken by ice or storms did not apply, because it would be powerful enough to carry many tons weight. The author had referred several times to the Royal Commission on London Traffic. He was inclined to think the real fun in connection with the transportation problem would begin after the Commission had reported. It was possible the Royal Commission might report in favour of shallow tunnels, but it was well to consider whether it would be worth while to carry out such a scheme. In the first place, he believed the public in a city like London would prefer to keep on the surface if they had facilities for travelling distances under a mile, and would not mind going down a tube provided they could get a fast conveyance from one fairly distant point to another fairly distant point. He thought London should not be placed in the unfortunate position in which New York found itself in 1901, when many of the main thoroughfares were in a state of perfect chaos owing to the building of the shallow tunnels. If the Traffic Commission reported in favour of any extension of street surface trams, he believed the fun would again begin, because that would be the greatest possible mistake in London. Having lost a good deal of money in a street locomotion undertaking, he advised those people who held shares in omnibus companies which were enterprising enough to go in for motor omnibuses not to part with their shares. He did not think the public would stand the breaking up of their streets for the purpose of increased surface trams, because not only would rapid transit on the surface be more difficult, but the trams would congest themselves as well as the streets. What London would have very soon, and what it would find much better than tramways, was a proper service of motor omnibuses. He was largely responsible for the first public service of motor omnibuses in Great Britain, viz., in Edinburgh, where at one time as many as twenty-nine public service omnibuses were running. Unfortunately money was lost in the undertaking, firstly, because a good manager could not be obtained, and, secondly, because the right sort of vehicle was not chosen. It would not stand the traffic and the work, and would only carry seven or eight passengers besides the driver. The right vehicle had now been constructed, and in a town that was decently paved, like London, the people would stay on the surface if they were given a good method of transportation. He would like to ask the author whether he said that the two circular railways in Berlin and Paris were built for military purposes.

Mr. PORTER replied that he thought the Berlin railway was.

The CHAIRMAN proposed a hearty vote of thanks to the author for his admirable paper. He had expressed the opinion in introducing Mr. Porter to the meeting that they might expect an important and practical paper, and he would say now that the result more than confirmed what he had said.

The resolution was then put and carried unanimously.

THE FOREIGN FRUIT INDUSTRY.

"Considering," writes Mr. John Plummer in the paper on Australian Fruit Produce in the last number of the *Journal*, "that in Australia the seasons are reversed, and that all the leading British and American summer fruits, such as cherries and strawberries, are most plentiful from November to February, there should be a large oversea market for them." No doubt there will be by-and-bye, but meantime the imports of fruit from Australasia are restricted mainly to apples, it being difficult to bring over pears in good condition, and impossible to do so with the softer fruits. It is a little surprising that our

fruit imports have shown very little expansion in recent years, at any rate until the last year or two. Take the first and last year of the decade 1892-1901. The value of the imports of the principal fruits was in round figures as follows:—

	1892.		1901.
	£.		£.
Apples....	1,354,000	..	1,183,000
Pears	297,000	..	296,000
Plums	200,000	..	244,000
Cherries ..	135,000	..	214,000
Grapes....	394,000	..	695,000
Total ..	2,380,000	..	2,632,000

The imports of apples and pears were of smaller value in 1901 than in 1892, and the only very marked increase was in grapes.

If we take the years since 1901 the increase is greater. The following figures give the comparison for the ten months ended October 31 of the years named:—

	1902.		1903.		1904.
	£.		£.		£.
Apples ..	1,156,987	..	1,837,199	..	1,584,168
Pears....	411,518	..	295,192	..	455,905
Plums ..	513,339	..	621,535	..	535,987
Cherries	216,421	..	167,142	..	319,969

The value of the whole of the fruits imported for the ten months ended October 31 of the three years 1902-4 was as follows:—1902, £7,198,049; 1903, £8,006,236; 1904, £8,008,165. Strawberries show a decrease from £58,080 to £49,536; almonds from £377,261 to £363,879; other nuts used as fruits from £426,172 to £378,556; and oranges, strange to say, from £1,783,219 to £1,629,000. The principal increases were in apples, from £1,156,987 to £1,584,168, largely due to increasing imports from the Dominion, and bananas, which imported to the value of £905,218 in the first ten months of 1902, were valued for the corresponding period of 1904 at £1,170,483, an expansion due to some extent to the increasing imports from the West Indies. The home area under orchards grows but not very rapidly, and is mainly confined to England, for it is almost at a standstill in Wales, and only increases slowly in Scotland. It is much the same with the home area under small fruit, though Scotland has a much larger acreage of small fruit than of orchards.

A brave attempt is being made to create a large fruit trade between the United Kingdom and the West Indies, and few ventures would seem to be more promising. The islands are within comparatively easy reach of England; cold storage has made it possible to preserve the most delicate fruits in good condition; fast steamers are at the disposal of shippers; the soil and climate are unsurpassed for tropical fruit production; there can be no solid prosperity in any of the islands whilst the present dependence upon the sugar industry remains undiminished, yet the fruit exports increase very slowly if Jamaica is excepted. And even in Jamaica the industry does not rest on a solid basis. A large fruit trade between Jamaica and the United States has been created during the last thirty-five years, greatly to the advantage of the island, and from time to time attempts have been made to create a similar trade with the Mother Country. But until quick and suitable steam transport could be secured this was impossible, and no such steamship service was procurable without an Imperial subvention not to be got. This initial obstacle was overcome three or four years ago, when the present Government agreed to pay a heavy subvention to Elder, Dempster and Co. for the required service. Since then the fruit exports, especially of bananas and oranges, show a large increase, but much remains to be done before the trade can be said to be in a healthy condition. There is a market on this side for all the fruit of good quality that Jamaica can supply, but quality is essential, and that is a truth that is only imperfectly grasped in Jamaica. The planters do not concern themselves with the taste of the market, they neglect grading, and are careless as to the condition in which the fruit reaches the consumer. For example, they grow a large, coarse banana, known as the *Gros Michel*, for the American market. It seems to suit the American taste, but English buyers prefer the smaller banana of the Canaries, *Musa Cavendishii*, and these fetch twice the price of the coarser kind. Nor is it only that the sort of banana sent is the wrong sort for the English market. No attention is paid to grading or to packing. Colour and size, too, are disregarded. The bananas that come from the Canaries are carefully graded and packed. They are wrapped in wadding and paper, and put into crates, and covered with banana tops or other soft stuff. When they reach port the same care is taken to get them to the fruit brokers quickly and without injury. The Jamaica bananas have no such care. They are lumped down in the steamers and when they get to Bristol are sent to London loose in trucks. The consequence is that the brokers can always get twice as much for bananas from the Canaries as from Jamaica, though there is no good reason why Jamaica bananas are not of equal quality and condition to those from the Canaries. It is the same with oranges. Jamaica might do an immense trade with England in oranges. Jamaica oranges can be put upon the market in excellent condition in October, when they have nothing to fear from competition. The Spanish and Mediterranean oranges are not eatable until after Christmas, so the West Indian variety has the market to itself for three months or more, and during that period large numbers are sold. But a much larger trade would be done, and better prices got, if more attention was paid to grading and packing. And so with mangoes. The home of the mango may be said to be India, and some years ago one of the native princes made a

serious attempt to create a large export trade in them with England but without success. They seldom arrived in good condition. But in Jamaica some of the best known Indian descriptions flourish, and all that is wanted to land them in excellent condition here is careful grading and packing, which they seldom get. And what is true of Jamaica is equally true of other West Indian islands. The pineapple, for example, flourishes everywhere, and some of the pines, the Montserrat for instance, are of very delicate flavour. But this pine is unsightly and not suitable for the English market. The best for this trade is the smooth Cayenne, grown so largely in the Azores, and now beginning to be grown in the West Indies. It has, too, to be remembered that the pine is grown for ornament as well as quality. The crown of the pine is the glory of it, and it is found that the "wind and weather" to which it is subject in the West Indies injures its appearance, a drawback that might easily be overcome by the erection of some sort of inexpensive sheltering. But nothing is done. Just as the English farmer thinks all that is necessary to make a paying orchard is to plant a certain number of apple trees without much regard to adaptation of kind to soil, and to pick them when ripe and send them anyhow to market, so the West Indian grower pays little attention to quality. But it is quality, as Mr. Monro, of King-street, Covent-garden, is never tired of insisting—and he is one of the biggest fruit-brokers in the kingdom—that is the one thing indispensable in fruits that are to secure any hold on public consumption.

The fruit exports of Cape Colony are growing slowly. They consist almost entirely of apricots, peaches, plums, and grapes, more especially grapes, and they reach this market just at the best time for sale, when English and Spanish supplies are getting scarce. Much more attention is given than in the West Indies to grading and packing, and the colony owes much to the late Mr. Rhodes for showing on his model farms how the fruit industry ought to be conducted. He got one of the best men for the work, Mr. Pickstone, to start the business, with skilled men, with the result that grading and packing are what they should be, and the fruit comes over in splendid condition. This cannot be said of all the fruit exports from the Cape, but the Rhodes example has told, and is telling.

It is largely a question of labour. The great expansion and success of the Californian fruit trade is chiefly due to the skill of the Chinese labourers, deftest of packers. And so in the Canaries, where the Spaniard, whom we are apt to think of as lazy and careless, shows the greatest care in grading and packing. For example, every tomato, of which millions are sent to England every year from the Canary Islands, is wrapped in paper and most carefully packed. The utmost attention is given to details of management, and the result is seen in the high prices commanded in the English market by the fruit products of the islands. Young farmers with a little capital might find it to their advantage to take it to Jamaica, Barbadoes, or Trinidad, and put it into fruit farms. But they should first master the business of fruit growing and export as worked in the Canaries and California, and they must remember that close and constant personal supervision is indispensable to success. The labour difficulty is not insuperable given tact and brains on the part of the grower.

PRECIOUS STONES IN CEYLON.

The precious stones found in Ceylon are rubies (*i.e.*, red sapphires), blue, yellow, white, pink, and occasionally green sapphires, and asterias (star stones), the latter being, when of fine quality and ruby-red colour, the most expensive fancy stones known, according to the American Consul at Colombo. The other gems are alexandrites, beryls, chrysoberyls, cats'-eyes, amethysts, garnets, moonstones, and zircons, also a red stone which the natives call "killinge." Gem mining is now purely a native industry, the work is done in a primitive manner, and frequently on the communal system. No great skill is exercised. A prospector selects a likely locality and pays the Government for a permit to mine for gems. Men then go to work digging a pit, generally from ten to fifty feet deep, sometimes deeper, until they reach the gravel in which the gems are found. This is carefully washed and sifted until every particle of value is obtained. Sometimes the harvest is rich, but oftener it is very poor, consequently the production of gems suitable for jewelling is not large, and the local demand for such stones is so fully equal to the supply that, except in cases where the specimens are really promising, rough stones are not sent abroad, but are cut and polished by the local lapidaries and readily sold by local jewellers, mostly to travellers. The pearl fisheries of Ceylon have been known and celebrated from time immemorial, and the output in 1903-4 was very profitable. Seasons occur at irregular intervals, owing to frequent disappearances of the oysters from mysterious natural causes, before they reach their proper age of production—four to six years. When they mature a fishery is advertised, and forthwith a vast throng of speculators and sight-seers from all parts of the world, but mostly from India, flocks to the scene of operations near Aripo, something over 120 miles north of Colombo. More than 200 boats manned by natives, and each possessing a complement of divers, come from far and near, and during the calm, smooth water months of March and April the fishing operations progress daily, the number of oysters obtained averaging about 1,000,000 per diem. The principal buyers are from the Coromandel and Malabar coasts of India, and that country receives a large share of the pearls. The next largest portion falls to the local speculators, who send a few to Europe, but find in the Ceylon market a ready sale and better price for those that are retained.

WOODEN COTTAGES AND INSURANCE.

In discussing rural housing in the last number of the *Journal*, the question of insurance was mentioned, and reference was made to the Norwich Union. Since then the writer of the article has had the advantage of discussing the point raised with the general manager of that great insurance society, who confirms what was said in the *Journal*, namely, that cottages of other than brick or stone are insurable to the amount of the rent charge. There is no kind of new cottage that is not insurable. It is simply a question of rate, and the rate is not prohibitive. Take the most inflammable, all wood, thatched, and in a row. The charge would be 7s. 6d. per cent. But thatch is no longer used for covering, and for a wooden cottage tiled, the rate is 5s. per cent., provided the local authority has approved of the heating arrangements, and there is proper separation of the cottages, one from the other, or there is a brick wall between two, carried up above the roof. What the insurance offices call "moral" risk does not weigh where cottages are put up by landowners although it might do so in the case of a speculative builder unable to sell or let his cottages. Anyway, the insurance difficulty, as applied to the erection of cottages by landowners or local authorities, disappears when examined. The owner of the most inflammable cottage, valued at £150, can guard against loss by an insurance charge of 11s. 3d. per annum, and in the case of the majority of wooden cottages of that value the annual charge would not exceed 7s. 6d.

OBITUARY.

LIONEL VAN OVEN.—Mr. Van Oven, who died on the 8th inst. at his residence at 6, York-terrace, Regent's-park, aged 75, had been a member of the Society of Arts since 1867, and he was an occasional contributor to the *Journal*. In 1870 he and Mr. Assur Moses were invited by the late Baroness Meyer de Rothschild to assist in founding the Association for the Oral Instruction of the Deaf and Dumb. He became greatly interested, and was an active worker in the cause, and on the death of the late Sir George Dasent became chairman of the executive committee of the institution. He continued to give unremitting attention to the work till 1898, when he resigned owing to ill-health. In 1887 he was appointed by Queen Victoria, on the recommendation of the late Earl Granville, as a member of the Royal Commission on the Blind, the Deaf, and Dumb, &c., under the chairmanship of Lord Egerton of Tatton, and took an active part in the inspection of the various institutions, and in the inquiry generally, both at home and abroad. In connection with the Royal Commission, two Acts of Parliament were passed, bringing both the blind and the deaf and dumb within the scope of the Education Acts. Mr. Van Oven was also president of the Union of Teachers of the Deaf on the Pure Oral System.

GENERAL NOTES.

THE UGANDA RAILWAY REPORT.—The report on the construction and working of the Mombasa-Victoria (Uganda) Railway and Steamboat Service on Lake Victoria just issued ("Africa," No. 16, 1904), is not, on the whole, an unsatisfactory record of progress necessarily slow. In the early part of the year under review the traffic working suffered, owing to the line being still incomplete in many respects, while from April to September heavy rains caused much delay. The financial forecast estimated the deficit of the year at £65,000, actually it was only £60,100. The original estimates for the current year's (1904-5) working showed a loss of £45,000, but the Manager's revised estimates, prepared in November, show a deficit of £10,000 only, and it is expected that a further reduction will take place in 1905-6. With reference to the deficit, it is pointed out that all Protectorate stores are carried at actual cost price, and that "without the facilities afforded by the railway the cost to the State of holding Uganda and the head waters of the Nile would have reached a sum twenty times greater than the apparent deficit. The cost of carriage of the amount of Government stores now used in the Uganda Protectorate by the old method of porters, would not only be sufficient to obliterate the deficit, but to pay a small percentage on the capital cost of the railway as well." It is to be noted that there was a constant increase in the downward traffic as from the Lake to the coast—35 per cent. of the total tonnage carried, as against 21⅜ per cent. for 1902—the upward or import traffic remaining almost stationary. Much of the increase downwards is due to the traffic brought in by the Lake steamers, which has the great advantage, so far as the railway is concerned, of passing over its whole length. A second steamer was put on the lake in January last, and a third is urgently required, and is about to be supplied. The working of the two steamers for the year showed a surplus on the cost of operating.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock:—

FEBRUARY 1.—"The Navigation of the Nile." By SIR WILLIAM H. PREECE, K.C.B., F.R.S. SIR ROBERT HANBURY BROWN, K.C.M.G., will preside.

FEBRUARY 8.—"Time Development in Photography, and Modern Mechanical Methods of carrying it out." By R. CHILD BAYLEY. GEORGE DAVISON will preside.

FEBRUARY 15.—"The Decline of the Country Town." By ARTHUR HENRY ANDERSON.

FEBRUARY 22.—"Some Misconceptions of Musical Pitch." By JOHN E. BORLAND. (*a*) *Visual*—due to conventional but inaccurate notation; (*b*) *Aural*—volume of tone mistaken for depth, brightness for height.

Illustrated by voices, instruments and diagrams.

MARCH 1.—"The British Art Section of the St. Louis Exhibition." By ISIDORE SPIELMANN, F.S.A. SIR EDWARD POYNTER, Bart., P.R.A., will preside.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

FEBRUARY 16.—"The Indian Census of 1901." By SIR CHARLES A. ELLIOTT, K.C.S.I., LL.B. The RIGHT HON. LORD GEORGE HAMILTON, G.C.S.I., M.P., will preside.

COLONIAL SECTION.

Tuesday afternoons at 4.30 o'clock:—

FEBRUARY 28.—"The Manufactures of Greater Britain.—I. Canada." By C. F. JUST, Canadian Government Service in London.

APPLIED ART SECTION.

Tuesdays, at 4.30 or 8 o'clock:—

JANUARY 31, 8 p.m.—"Calligraphy and Illumination." Two Papers. By EDWARD JOHNSTON and GRAILY HEWITT. LEWIS FOREMAN DAY, Vice-President of the Society, will preside.

CANTOR LECTURES.

Monday evenings, at 8 o'clock:—

JAMES P. MAGINNIS, Assoc.M.Inst.C.E., M.Inst.Mech.E., "Reservoir, Stylographic, and Fountain Pens." Three Lectures.

LECTURE II.—JANUARY 30.—*Stylographic Pens.*—Rudimentary forms—Early patents—Rigid points, needle points—Various writing or marking pens—Modern Stylographic pens, Nota Bene, Cygnet, and others—Gold pens, description of manufacture.

LECTURE III.—FEBRUARY 6.—*Fountain Pens.*—Early patents—Solid ink—Various reed arrangements — Self-filling reservoirs, flexible reservoirs, piston and plunger—Modern types of Fountain pens, Swan, Ideal, Conklin, Pelican, Unleakable, Wirt, Quill, Post, Autofiller, Fleet, &c.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JAN. 30...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Mr. James P. Maginnis, "Reservoir, Stylographic, and Fountain Pens." (Lecture II.)

Farmers' Club, Whitehall-rooms, Whitehall-place, S.W., 4 p.m. Mr. Robert A. Yerburgh, "Agricultural Co-operation."

Surveyors, 12, Great George-street, S.W., 8 p.m. Discussion on the papers read by Mr. Stenning and Mr. Menzies.

Actuaries, Staples-inn Hall, Holborn, 5 p.m.

Camera Club, Charing-cross-road, W.C., 8½ p.m. Mr. E. R. Dibden, "The Magic Carpet."

London Institution, Finsbury-circus, E.C., 5 p.m. Mr. B. Kidd, "Social Evolution among Social Insects."

Faraday Society, 92, Victoria-street, S.W., 8 p.m. 1. Mr. John G. A. Rhodin, "Mass Analyses of Muntz's metal by Electrolysis, and some Notes on the Electrolytic Properties of this Alloy." 2. Prof. R. Beckett Denison, "The Equilibrium between Sodium and Magnesium Sulphates." 3. Mr. E. Kilburn Scott, "Refractory Materials."

East India Association, Caxton Hall, Westminster, S.W., 4 p.m. Mr. S. S. Thorburn, "The Place of India Under Protection."

TUESDAY, JAN. 31...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Applied Art Section.) Mr. Edward Johnston and Mr. Graily Hewitt, "Calligraphy and Illumination." Two Papers.

Royal Institution, Albemarle-street, W., 5 p.m. Prof. L. C. Miall, "The Structure and Life of Animals." (Lecture III.)

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Mr. L. E. Clark, "Floating Docks."

WEDNESDAY, FEB. 1...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Sir William H. Preece, "The Navigation of the Nile."

Geological, Burlington-house, W., 8 p.m.

Sanitary Engineers, 19, Bloomsbury-square, W.C., 7 p.m. Presidential Address by Mr. J. A. Crowthier, "The Bye-Laws."

Royal Archæological Institution, 20, Hanover-square, W., 4 p.m.

Obstetrical, 20, Hanover-square, W., 8 p.m. Annual Meeting.

THURSDAY, FEB. 2..Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

Linnean, Burlington-house, W., 8 p.m. 1. Mr. W. J. Futcher, "New Chinese Plants from the neighbourhood of Hong Kong." 2. Dr. H. J. Hausen, "European Marine Species of Cirolaninæ (Isopoda)."

Chemical, Burlington-house, W 8 p.m. Messrs. M. O. Forster and H. E. Fierz, "Studies in the camphane series. (Part XVI.) Camphorylcarbimide and isomeric camphorylcarbamides."

London Institution, Finsbury-circus, E.C., 6 p.m. Mr. Henry Tiedeman, "The Balkans."

Royal Institution, Albemarle-street, W., 5 p.m. Prof. W. Schlich, "Forestry in the British Empire." (Lecture I.)

Civil and Mechanical Engineers, Caxton-hall, Westminster, S.W., 8 p.m. Mr. A. R. Tattersall, "The Mechanics of Flour Milling."

Camera Club, Charing-cross-road, W.C., 8½ p.m.

FRIDAY, FEB. 3...Royal Institution, Albemarle-street, W., 8 p.m. Weekly Meeting. 9 p.m., Prof. T. Clifford Allbutt, "Blood Pressure in Man."

Geologists' Association, University College, W.C., 7½ p.m. Annual General Meeting. Address by the President, "Modern Methods in the Study of Fossils."

Philological, University College, W.C., 8 p.m.

Quekett Microscopical Club, 20, Hanover-square, W.C., 8 p.m.

SATURDAY, FEB. 4...Royal Institution, Albemarle-street, W., 3 p.m. Sir Alexander Mackenzie, "The Bohemian School of Music." (Lecture I.)

Journal of the Society of Arts.

No. 2,724. VOL. LIII.

FRIDAY, FEBRUARY 3, 1905.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

NOTICES.

NEXT WEEK.

MONDAY, FEBRUARY 6, 8 p.m. (Cantor Lecture.) JAMES P. MAGINNIS, "Reservoir, Stylographic, and Fountain Pens." Lecture III.

WEDNESDAY, FEBRUARY 8, 8 p.m. (Ordinary Meeting.) R. CHILD BAYLEY, "Time Development in Photography, and Modern Mechanical Methods of Carrying it out."

Further details of the Society's meetings will be found at the end of this number.

CANTOR LECTURES.

Mr. JAMES P. MAGINNIS delivered on Monday evening, 30th January, the second lecture of his course on "Reservoir, Stylographic, and Fountain Pens."

The lectures will be published in the *Journal* during the summer recess.

APPLIED ART SECTION.

Tuesday evening, January 31st; LEWIS FOREMAN DAY, F.S.A., in the chair. Two papers were read by EDWARD JOHNSTON and GRAILY HEWITT on "Calligraphy and Illumination."

The papers and report of the discussion will be published in a future number of the *Journal.*

VIVÂ VOCE EXAMINATIONS IN MODERN LANGUAGES.

The following is a list of the *Vivâ Voce* Examinations which have been held since the last announcement in the *Journal* for June 24, 1904:—

Place of Examination.	Date.	Number of Candidates.	Passed with Distinction.	Passed.	Failed.
French :—					
L.C.C. Evening School, Offord-road, Barnsbury	June 27, 1904.	21	2	15	7
L.C.C. Evening School, Plough-road, Clapham Junction	June 28, 1904.	17	1	11	5
L.C.C. Evening School, Queen's-road, Dalston	June 29, 1904.	13	5	6	2
L.C.C. Evening School, Offord-road, Barnsbury	June 30, 1904.	24	5	16	3
L.C.C. Evening School, Sussex-road, Brixton	July 1, 1904.	27	5	16	6
Municipal School of Science, Brighton......	July 11, 1904.	14	1	10	3
Merchant Venturers' College, Bristol.........	July 12 & 13, 1904.	68	4	33	31
German :—					
L.C.C. Evening School, Queen's-road, Dalston	June 20, 1904.	16	5	8	3
L.C.C. Evening School, Offord-road, Barnsbury	June 23, 1904.	17	2	6	9
Merchant Venturers' College, Bristol.........	July 14, 1904.	35	3	20	12
Spanish :—					
L.C.C. Evening School Queen's-road, Dalston	July 14, 1904.	14	2	7	
		269	35	148	86

The Examiners were Mr. E. L. Naftel for French, Professor H. G. Atkins, M.A., for German, and Professor Ramirez for Spanish.

COVERS FOR JOURNAL.

For the convenience of members wishing to bind their volumes of the *Journal,* cloth covers will be supplied, post free, for 1s. 6d. each, on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

INDIAN SECTION.

Thursday afternoon, January 19th; Sir WILLIAM LEE-WARNER, K.C.S.I., in the chair.

The CHAIRMAN said the presence of such a large audience was a sufficient indication that they were all acquainted with the author and knew what to expect from him. He considered the Section was extremely fortunate in having got Mr. Freshfield to comply with its request that he would give a paper that afternoon on the subject of Sikkim. As one of the founders of the Alpine Club he was known to many; to more as an expert in geographical knowledge, having attained the highest honours which it was possible to obtain from the Geographical Society in this country; and to a larger circle he was still better known by the charming books he had written on the Caucasus, Kangchenjunga, and other subjects.

The paper read was—

THE GATES OF TIBET.

By DOUGLAS W. FRESHFIELD.

When I first undertook to address an audience belonging to this Society, I did not realise that the invitation came from a specifically Indian Section. Had I done so I might have hesitated to accept it. For I have learnt by frequent experiences during a long geographical career that Anglo-Indians, those who have spent a large part of their lives, a quarter of a century or more, in a tropical climate, are extremely critical as to any remarks the fair-weather tourist, or "globe trotter," as they call him, may venture with reference to the scene of their labours. The attitude is, I admit, natural, in many cases justifiable, and I am not at all disposed to complain of it. But when I suggested this consideration to Sir William Lee-Warner he kindly replied that I might count on indulgence in the Society of Arts because I was regarded as an artistic traveller. Now an artist, I believe, is one who embellishes facts. There may be, even on the Tibetan frontier, travellers answering to this description. The Himalaya, like the Alps, may have their Tartarin. But I have no ambition, even had I the power, to rival such feats. As Wordsworth wrote, "The moving accident is not my trade." I am no artist with pen or pencil.

I must look in another direction for an excuse for my audacity in facing you this afternoon. I reflect that the country I am invited to talk about, the frontier land of Tibet, is, after all, not India at all, and linked only to India by the newest of political bonds: that in its natural characteristics and its population it is a wholly distinct region, which comes within the scope of but few Anglo-Indians, and which even a high ex-official may know very little about.

The first and the most abiding impression made on the newcomer from India on his arrival at Darjeeling is that he has entered another country, almost another quarter of the globe; he recognises that he has changed not only sky and landscape, but architecture, people, and religion. Broad-framed, wide-faced, thickly-clad, laughing Tartars, a trifle "smouchy," to adopt Charles Lamb's epithet, take the place of the slender, thinly-clad, melancholy Bengalees; Buddhist temples and chortens and prayer-flags have supplanted the village shrines. Instead of vast alluvial plains he finds himself perched on and surrounded by ridges and slopes on which there is hardly level enough to build a house. And as to scenery; I have already added one to the too numerous descriptions of the indescribable splendours of the view from Darjeeling, when, in the sunset glow, Kangchenjunga raises its majestic brow, like a lone beacon-light from another world, above the hundred folds of the foothills and the stark crests of the lesser snows. You need not fear I shall repeat the vain attempt to-day. I propose to do better; to illustrate the scenery of Sikkim by showing you a series of photographic views mostly taken by my companion, Signor Vittorio Sella.

I must now ask your attention for a brief description of the geography of Sikkim, of the district that, owing chiefly to political accident, is the main southern gate of Tibet. The facts I shall lay before you have little or no claim to be novel, but since they have been somewhat obscured lately in the crooked vision of partisans, it may be no waste of time to re-state them. When any question comes within the sphere of practical politics, it comes also within the sphere of party prejudices. It is not I think artists, but politicians who are most prone to disregard or distort facts which do not appear to fit in with their pre-

possessions. Those who disapprove of the recent penetration (it might be a stretch of words to call it a pacific penetration) of Tibet, have naturally felt inclined to believe the very worst as to the inaccessibility and the inhospitality of that country, the fanaticism and poverty of its inhabitants, and the consequent difficulty of entering into trade relations with them. Those who, rightly or wrongly, demur to every action that may result in extending British influence and British responsibility, those also who distrust an energetic Viceroy, were naturally prepossessed against the recent expedition. In the imagination of some of these critics Tibet looms large as a sort of Caliban's Island "desert, uninhabitable, almost inacessible." Now, "the use of travelling," as Dr. Johnson says, "is to regulate imagination by reality, and instead of thinking how things may be to see them as they are." I am not concerned here to-day to dispute a political opinion. But I protest against the attempts that have been made in some quarters to justify it by statements which are either not in accordance with the facts, or represent an imperfect apprehension of them. Thus it has been alleged that Tibet is remote and inaccessible—that it is practically a frostbound desert, untraversable by an army, and never traversed by one—that its inhabitants are as fierce and fanatical as Afghans, and ought to be approached with the same precaution—that the region is beyond the political influence of Russia, has not lately been the scene of Russian intrigues, and could never become a path for Russian aggression. These are, I think, fair specimens of the statements that were put before the public during the early stages of the recent expedition.

Let us briefly examine some of these statements. The present frontier of Tibet, the point from which in 1888 the Tibetans invaded British territory, is about 350 miles from Calcutta, nearer that is by some 200 miles to the seat of Government than the Russian post at Penjdeh is to Peshawar. From the Tibetan frontier Lhasa is (according to the Sikkim Roadbook) about 250 miles by a route which presents no serious physical obstacles to commerce during many months of the year.

The possibility of moving an army across the Eastern Himalaya into India has been proved. In 1792 the Chinese sent an army of 60,000 men into Tibet, and marched down to within 15 miles of Katmandu, the capital of Nepal, where they fought a battle which resulted in the submission of the Nepalese, thus proving the penetrability of the Eastern Himalaya to a large force. Katmandu, of course, is short of the plains of India, but it is as much across the Himalaya as Domo d'Ossola is across the Alps. What the Chinese did once they might easily do again should China ever become a vassal State of Russia. This fact disposes of what a German writer calls Sven Hedin's "exceedingly warm and passionate argument against the British advance on Lhasa."

And as to the military aspect of the Tibetan frontier Major O'Connor reported in 1903, "beyond Khamba Jong the country offers absolutely no difficulty in transporting an army in any direction, as all the tops of the hills and passes leading into Tibet are flat."

Next as to Tibet being a desert. This is a generalisation that has perhaps been formed from bird's-eye views of the uplifted region on the Sikkim frontier, coupled with the narratives of the travellers, Sven Hedin and Littledale, who have crossed the deserts of northern Tibet in their anxiety to escape notice while looking for a backdoor to Lhasa. On first view, it is true, the traveller who has found his way through the mazes of the foot-hills and up the gorges of Sikkim to the top of the long staircase that leads from the plains of India to Tibet is struck by the apparent barrenness of his surroundings. He sees extensive, almost level plains, treeless, and clad only in parts with sparse brown herbage, girt and divided by low ridges. Icy peaks fringe the horizon. In the absence of definite valleys, sluggish streams meander aimlessly across the wide landscape between tawny slopes and beds of skyblue gentians. It is an open country. The only signs of life are the summer stations of the herdsmen, or rare villages overlooked by the high white walls and flagcapt parapets of monastic fortresses. But this is only the rim or rind of Tibet, and even in this rind there are soft spots. Thus Major O'Connor writes (July 18th, 1903):—"Major Bretherton made this morning a reconnaissance towards the southwest, and found a rich and fertile valley some three to four miles from Khamba Jong, where grazing is abundant, and where barley crops are raised and cattle are reared."

A few marches more and the traveller reaches the cultivated region leading to the valley of the Brahmaputra, to which the above description equally applies, as appears from an official report. I may further refer to the description in Mr. Candler's recently-published volume of an "Arcadia in Tibet."

I understand that the valley of the Brahmaputra from Lhasa westwards has been found by the recent Mission to be for a long distance well inhabited and cultivated. The valley of the Brahmaputra is the real Tibet. Generalisations framed from visits to the southern frontier are like descriptions of England founded on glimpses of the Scotch Borders.

The Tibetans are very far from resembling the fanatical Afghans. They are not a warlike people and have never proved themselves formidable. "They are a pastoral people and a trading people, and their religion is a tolerant one," writes Hooker's companion Dr. Campbell. "Until 1783" (until, that is, China had asserted her supremacy), he adds, "the Tibetans were friendly to trade with us."

It would be superfluous, I believe, after what is known to have occurred after the visits of the Lamas to Livadia and St. Petersburg and the flight of the Dalai Lama with his Russian adviser into the Czar's dominions, to deny that Russia has had relations with Tibet. Neither the Russian Government nor the Russian Press has attempted to conceal a fact they know to be publicly recognised not only in England but also in Germany, as is shown in an excellent little volume compiled by Dr. Wegener, which I may have occasion further to quote.

Having, I hope, cleared the ground of these misapprehensions, I will proceed to a more detailed description of Sikkim as the Gate of Tibet. The political state of Sikkim, together with the districts of Darjeeling and Kalimpong (the latter once part of Bhutan), formally annexed to India, coincides at present with the basin of the Tista. From the Himalayan watershed (164,000 feet) to the plains that river runs for about 100 miles in a direct line (more, of course, following its meanders) through a rapidly deepening trench. It is fed by numerous tributaries flowing out of side glens which run up to the vast glaciers of Kangchenjunga on the west and to the lesser snows on the east. At first its trench is broad, but opposite Kangchenjunga (at 8,000 feet) it suddenly drops and becomes a precipitous gorge, which, until the British had mended the track (which was before my visit in 1899), was often impassable for months even for coolies, and was never passable for beasts of burden. Lower down, the Tista runs in a deep valley through soft, billowy foothills, whose slopes are apt to slip away in the rains. This is the track by which I rode up to the back of Kangchenjunga, and this was the track by which we moved troops to Khamba Jong at the commencement of the late frontier troubles. The difficulties are similar to those of many a mule track up an Italian Alpine valley; that is nothing for travellers, but considerable for the impedimenta of an armed force. This route, till a few years ago, having been impracticable for any beast of burden, has never been the trade route to Tibet. That passed up the valley of the next stream parallel to the Tista on the east, the Ammo Chu. Owing to the lower reach of its valley lying in Bhutan, the middle course of the Ammo Chu was reached by crossing a pass either from Bhutan on the east or the Tista Valley on the west.

The passes from the West, about 14,000 feet high (of which the Jelep La, the Yak La, and the Cho La are the best known), are passes of the character of the mule-paths round Mont Blanc. A lady who has been to the Jelep La tells me "it would be a capital place for a picnic for a boys' school" such as go on holiday excursions in the Alps. But what is fun for boys or summer tourists may, of course, be a very different matter for an army, particularly an Indian army with its crowd of followers. Once in the Ammo Chu Valley, there is little further difficulty in climbing to the broad watershed at its head, and descending over the bleak uplands to Gyangtze. This is the commercial travellers' track to Lhasa, and the late expedition reports that there is no serious difficulty for an unopposed force or caravan at any spot on the road.

Have any of my audience been up the Adige from the South?

The traveller going up the Tista to the watershed may compare his first stage to the hills about Trent, his second to the gorges about Botzen, and the third to the open region above Brixen—towards the Pusterthal. The parallel is by no means perfect, but it may serve for want of a better.

The main point to realise is that Tibetan scenery begins, and Sikkim scenery ends many miles south of the watershed, and at a height of 8,000 to 10,000 feet. Below are V-shaped valleys, gorges, steep cliffs, dense tropical forests, a region formerly accessible only on foot; above are shallow troughs and bare rolling hills, "like Wiltshire Downs" (I borrow the expression from Major O'Connor). The one is a country modelled by water, the other a country modelled by ice. The destructive agent has dug deep furrows, the conservative

THE ROADS FROM SIKHIM INTO TIBET.

Scale of Miles

20 5 0 10 20 30

Nat. Scale 1: 1.500.000 or 23.67 miles • 1 inch.

This map has been kindly lent by the Royal Geographical Society.

agent has preserved the primeval smoothness of a land recently emerged from an ice age. Some of Prof. Garwood's photographs of Spitzbergen remind me, in the surface outlines, of the country behind Kangchenjunga.

This configuration of the earth's surface has had naturally great influence on its population, and consequently on political boundaries. In Sikkim in the old days, communications were strangely difficult; the hillsides slipping down in blocks under the perpetual rains, the torrents with their rope-bridges, could only be affronted by sturdy pedestrians. But above the timberline yaks, and even light carts in many places, travel easily. The Tibetans consequently used and occupied the upper pasture region south of the watershed, just as the Germans seized the heads of the valleys south of Monte Rosa. Their herds roamed over Lhonak and the sources of the Tista. They paid no respect to the opinion of geographers that a watershed is a proper political boundary. They practically extended Tibet to the point at which it became too hot for their yaks. Hooker was told he had reached "Cheen," at the Zemu bridge, a mile or two above Lachen.

Sikkim was a decaying State. Its natural fate was to be eaten up by its neighbours Nepal and Tibet. We stepped in and saved it; but in the usual happy-go-lucky way of our statesmen, for some time, took little pains to ascertain its actual boundaries. When I went out to India five years ago the official Indian maps differed between themselves as to the frontier.

It was not till after the war of 1888 that we perambulated the northern boundary and set up certain pillars which the Tibetans promptly disregarded and destroyed. They subsequently proceeded to build a wall across the Upper Tista and forbade access to its passes. These Tibetan aggressions were at first overlooked. We did, however, turn out the monks who had established themselves in a monastery at Chung Chang, at the junction of the two sources of the Tista, the Lachen and Lachung valleys. But till 1902, we took no steps to reclaim for Sikkim the pastures up to the watershed, that is the region of Lhonak, uninhabited, but yearly visited by the Tibetan herds.

In the next valley, that of the Ammo Chu, the Tibetans had fixed themselves more firmly. At Phari, at the very head of the dale, was an old Tibetan frontier fortress commanding the trade route to Lhasa. Lower down the valley a powerful monastery owned most of the land. The Bhutanese and Sikkimese monks quarrelled for possession of the monastery and (regardless of Æsop) called in the rulers of Lhasa as arbiters. The natural result followed.

The Tibetans established their frontier 30 miles south of Phari, at Gnatong, enclosing the fertile district of Chumbi. The date of this occupation I cannot fix precisely. It took place apparently in the first half of the nineteenth century, between 1800, the date of publication of Turner's volume, and Hooker's travels in 1848. In d'Anville's and Turner's maps the frontier of Tibet is drawn just below Phari. In October, 1903, Sir F. Younghusband writes:—"Chumbi Valley is on the Indian side of the watershed, and is not regarded as part of Tibet." Mr. Candler says "the valley is beautiful beyond the beauty of the grandest Alpine scenery." "One might imagine oneself in Kandersteg or Lauterbrunnen." "There are long strips of arable land and villages every two or three miles." The elevation of this oasis between the fierce heat of the foothills and the bleak downs of the Tibetan frontier is from 9,000 to 10,000 feet.

In the occupation of Chumbi by Tibet, we acquiesced even after the Tibetans had in 1888 used it as a base from which to invade Sikkim. Yet it is only necessary to glance at a map to see that this wedge or tongue of Chumbi, lolled out Tibetan fashion at us across the watershed, is no part of Tibet proper. Nor are the inhabitants Tibetans; they are, as Mr. Candler has told us, a separate and oppressed race, who "were unaffectedly glad to see us in their valley." But up to to-day there is no sign that these obvious facts—which I was at pains to insist on in my book published in 1903—have been appreciated by our rulers, and I fear lest once more the indifference of statesmen in England to geographical knowledge may throw away the main advantages which should have been the legitimate fruit of the late expedition. The Chumbi Valley is all that Darjeeling is not. It furnishes a health station beyond the first fury of the rains. It supplies an admirable strategic centre for the ward of the frontier, while Darjeeling is an isolated hilltop from which the first move involves a descent of over 6,000 feet. Again, lying as it does on the great trade route Chumbi has every advantage as a commercial mart and exchange. It is the very spot for "the annual fair or bazaar to be held for two months in the spring at some place near the frontier" recommended by Dr. Campbell.

If the next Blue-book does not show that our Government is taking steps to establish such a mart either close to or within the Tibetan frontier we shall be driven to conclude that its policy is not to establish relations with Tibet, but to compel its population to remain as regards India in the isolation to which the steadfast policy of China has condemned them.

I do not overlook the general or particular objections to annexation. We should, it may be said, make enemies of the Tibetans. I wait for someone who has been to Lhasa to tell me that they would not prefer giving us a long lease of Chumbi to paying an indemnity. We should, it may be added, be breaking our pledges to Russia? But why did we give pledges? Apart from the question whether it was necessary to give any pledge to that Power, surely a statesman knowing all the facts must have limited his pledge to territory north of the Indian watershed, inhabited by Tibetans, and forming part of Tibet proper. In keeping Chumbi we should not annex part of Tibet, but recover a territory to which it has no claim but that of occupation.

I have spoken of Chumbi's important position on a trade route, a route of little more than 300 miles from the plains to Lhasa. This route will shortly be made a cart track throughout, for leave has been got from the Bhutanese to make a road through their territory which will reach Chumbi without crossing the Jelep La or any high pass. But a route is no use where there is no trade. I believe you will learn shortly that the prospects of trade with Tibet are by no means so hopeless as has often been asserted, that the people have something to sell as well as needs to supply. Sir F. Younghusband looks forward particularly, I am told, to the trade in wool. Sir J. Ware Edgar, in a very able Report written in 1873, insists on its importance. I have found a singular support for this anticipation in the *Journal* of your Society. As long ago as 1869 Dr. Alexander Campbell, Sir J. Hooker's companion, read a paper before the Indian Section on the prospects of trade with Tibet, from which I will make a few (I should have liked to make longer) extracts.

"The principal imports into Tibet are English broad cloths, cutlery, indigo, tobacco, sugar, rice, cotton, sheetings, castor oil, silk, crockery, &c.

"Wool is a very important product of Tibet, and may be looked to as a valuable export. In that country and the adjoining ones there are immense tracts of pasture land on which flocks of sheep in almost countless numbers are maintained. Seven or eight thousand sheep is a common number even for ordinary graziers to possess.

"The great elevation and cold temperature of these countries with the fine pastures produce very heavy fleeces of the finest wool, and of a very long staple quite as fine as the Australian wools, but more valuable for many fabrics on account of its longer staple. While at Darjeeling I procured several loads of this wool, and sent samples of it with rate of cost for trial and export to Calcutta and elsewhere. It was highly spoken of, and the industrial school at Jubblepore, in the Central Provinces of India, celebrated for its fine carpets, offered to send me a lac of rupees (£10,000) to be laid out in purchasing wool for them at the rates I had quoted. I need scarcely say it was not procurable, but the wool is in Tibet in immense quantity."

The Parliamentary papers issued last year will furnish more recent information to inquirers. Despite all the obstacles created by the Tibetans and Chinese, the trade has proved, on the whole, a growing one. I will be brief in my statistics. In 1890-1 the exports from Tibet into India amounted in round figures to 770,000 rupees, the imports to 401,000 rupees. In 1902-3 the figures were, exports 1,990,000 rupees, and imports 1,152,000 rupees. During the same period the value of the cattle exported rose from 25,000 to 80,000 rupees; of wool from 351,000 to 1,030,000 rupees; and of borax from 90,000 to 345,000 rupees.

It stands to reason that the demand for tea in Tibet, hitherto met by caravans making a two months' journey from China, could be met more advantageously to the consumer by the tea planter of Darjeeling or Assam. But apparently he has yet to learn to adulterate his tea so as to suit the depraved taste of the Tibetans. They prefer a bad quality, sweepings not sugared but buttered. If this obstacle can be overcome, files of tea carts ought soon to be climbing the new road to Chumbi.

I do not wish to exaggerate the trade prospects. Relatively no doubt they are insignificant, but I believe they are substantial. Moreover their political as well as their financial result has to be looked to. I say nothing about minerals, because I believe sufficient is not yet known to make any statement trustworthy.

The Sikkim gateway, the central gateway into Tibet, is for the time being the most available, but there are sidedoors which may prove important in the future. It would lead me too far afield to attempt to describe them. I must dismiss them in a few words.

Nepal and Bhutan close many routes known to the natives, among them that by which the

Chinese army advanced in 1792. West of Nepal there is a route from Simla now being opened up, we hope, by Captain Rawling.

Through Bhutan there are several passes kept shut to Europeans. Further east, through the independent tribes on the verge of the great bend of the Brahmaputra, there is another route. This, Sarat Chandra Das, the native agent of the Indian Government, to whom until last autumn we owed our only recent account of Lhasa, wrote to me a year ago, he was most anxious to see investigated.

To link the Sanpo of Tibet with the Brahmaputra of Assam, to ascertain the character of the great gorge by which the river cuts the Himalaya, is one of the most interesting of the geographical problems on the earth's surface that remain to be solved. I feel assured that two such ardent geographers as my fellow medallists of the Royal Geographical Society, Lord Curzon and Sir F. Younghusband, are not the men to have willingly lost an opportunity to solve it. Why, when Captain Rawling was sent up the Brahmaputra to the furthest end of Western Tibet, was not another party sent down the river to make this long desired discovery? Why (as Mr. Candler tells us), after every preparation had been made, after the Lamas had given consent, after Mr. Needham, the highest local authority on all matters in Assam, had pronounced the risk small, and proposed to co-operate, was the expedition suddenly stopped by orders from Simla? I am not in a position to answer the question, but I anticipate that we shall be told statesmanship has nothing to do with geography (which is too often true), and that the gain did not justify the risk. The answer will, in my opinion, be inadequate, for the injury is not to science alone. The opening of a route in this direction would be a matter of commercial and political importance as well as of geographical interest. The eastern end of Tibet, which would be opened, is said to be the most fertile and populated. May we not hope that the expedition is only postponed until next spring? With the assent of the authorities at Lhasa, which was not withheld, Chandra Das assured me a small escort, say 200 to 300 men, would suffice to protect the survey party from any hill tribes it might encounter.

With regard to these west and east gates of Tibet, I am, I find, only echoing what was said by Lord William Hay, the Chairman of the meeting when these matters were discussed in 1869. He urged the survey of the Assam route and the completion of the road from Simla.

In every little war waged on the world-wide frontiers of the Empire, we run two risks: First, that we should undertake the business in hand with inadequate preparation. This has been avoided in the present instance. Next, that we should miss the fruits of our success owing to the timidity, or carelessness, or lack of geographical insight in our statesmen, or the divided counsels of the home and local Governments. Let me quote once more Dr. Wegener. He writes:—"Without doubt the arrival of the English at Lhasa is an epoch-making event in the history of Asia, the results of which will be awaited with the keenest interest. But this English expedition is not yet brought to a conclusion. England has still to secure the political fruits of a military action, which it must in fairness be acknowledged has been brilliantly carried through, and this must involve many difficulties and perhaps some unforeseen incidents." May we still hope that in the case of Tibet these difficulties may be avoided: that we may have no "regrettable incidents" to record; that we shall see the Chumbi Valley leased to us, and a garrison and a trade-mart established in it; that the needful steps will be taken and persevered in for promoting commercial intercourse with Tibet, and thus acquiring a political influence over our interesting neighbours which may tend to the peace and happiness of all concerned? If we do none of these things, well (I will venture to prophecy) we shall soon be on the march again to Lhasa.

On all these matters we shall have an opportunity before long of hearing at the Geographical Society the experience and the views of Sir F. Younghusband. We shall doubtless soon learn much more from the important work promised by Mr. Landon, *The Times* correspondent. I have only done my best, under some difficulties, to give an outline of the earlier knowledge of the region. I must turn to the tour my photographs illustrate, my own tour, which happened to be the first made by Europeans round Kangchenjunga. I have described this journey at sufficient length in a book, and I shall attempt no connected narrative this afternoon. I may, however, give a few leading facts before I proceed to show and comment on the beautiful series of photographs (I can only show a small percentage of them) taken by my companion, Signor Vittorio Sella.

The permanent obstacle to this excursion from Darjeeling has been and is the fact that all the western side of Kangchenjunga lies in the forbidden State of Nepal. We evaded the Nepalese guards by crossing a very lofty snow pass of over 20,000 feet at the back of Kangchenjunga and traversing a region where for three weeks we met no human beings. The herdsmen had been driven down by what was to us an exceptional obstacle, the terrible storm which devastated Darjeeling and lowered the snow level on the Kangchenjunga group 3,000 feet.

Our outward route led us past Gantok, the capital of Sikkim, where the Raja holds his court in a massive stone building lately constructed by the Indian Government, and then along the road up the Tista Valley to the village of Lachen. Here we turned and followed to its utmost source under the precipices of Kangchenjunga the immense Zemu glacier. At 15,000 feet the great storm overtook us, and we turned north to find a passage into Nepal. Our course led us across two passes higher than Mont Blanc—this is a favourite phrase just now, but please remember that on the borders of Tibet a pass higher than Mont Blanc may be as easy as the Wengern Alp. We then penetrated the weird pasturage basin of Lhonak, which is the sort of place some people imagine all Tibet to be—a broad bare basin encircled by snow and ice. It took us five days to get over the chain connecting Kangchenjunga with the Himalayan tableland. Below the snowlevel on the Nepalese side, we discovered another trunk glacier grander than the Zemu, if not so large. We passed close under the mighty cliffs of Jannu, and at Khunza, in Nepal, touched Sir Joseph Hooker's tracks, having supplied the missing link in his travels. Our return to Darjeeling was over known ground.

The whole tour took about seven weeks and involved a prodigious amount of up-and-down work. But we met with nothing that could be called a mountaineering difficulty according to the standard of the Alpine Club. Apart from the snowstorm our difficulties were difficulties of transport and commissariat.

There is a suggestion I would venture for the benefit of future travellers in this enchanting region. If the Indian Government could spare funds to make a horse-track from Tonglo to Jongri and from Jongri to Yoksun, and repair the bridges, it would bring within the reach of every visitor to India one of the most beautiful "round-tours" in the world. If a trail could be cut through ten miles of forest above Zemu-Samdong the glories of the Zemu glacier, of Kangchenjunga's northern cliffs and Siniolchum's snows would be rendered accessible to travellers. It is a small matter, and I fear too æsthetie for official notice, unless indeed it should find favour in the eyes of the present Viceroy.

I shall venture a second suggestion of greater general importance. Much new geographical information, if not so much as we had hoped, will be brought home by the surveyors attached to the recent expedition. I am told that the maps embodying this knowledge are likely to be considered confidential. I do not question the expediency in certain cases of keeping back large scale maps that might be serviceable for military purposes. But if the Tibetan frontier is held to be a locality where this precaution is essential, I trust that secrecy will not be carried at Calcutta to the length it has been sometimes in the past, and that the new maps will be allowed to be used as material for the correction of ordinary atlases. When this is not done errors, that have been proved to be errors, are liable to remain uncorrected in atlases (the scale of which renders any danger of their serving for military purposes wholly imaginary) of the highest authority among their class. In such cases a properly organised department should find no difficulty in supplying atlas compilers with the information they need to make their maps correct without divulging dangerous details. Both on scientific and public grounds, therefore, I feel it desirable to take this opportunity of expressing the earnest hope of all geographers that in the case of the Tibetan expedition only such restrictions as may appear indispensable to the highest authorities, military and civil, will be imposed on the promulgation of the fresh facts ascertained by its members.

DISCUSSION.

The CHAIRMAN expressed his own, and he believed the general conviction, that Mr. Freshfield had not only charmed his large audience with his paper and his photographs, but had also infected his hearers with his own enthusiasm, and sent them away with much food for reflection. Part of his suggestion concerned the future commerce and political relation of Tibet. Into that region it would be premature to enter, not only because, as the author had said, we were expecting a lecture in another place from Sir F. Younghusband, but also because the public were

awaiting the issue of a second Blue-book, which might give us surer ground for conclusions and speculations. Meanwhile a host of other considerations presented themselves for discussion. Mr. Freshfield was too modest to enrol himself in the corps of Anglo-Indians, but he need not hesitate, as he had shown that he possessed all the qualifications needed for enlistment. In the first place, he had caught the spirit which moved all our countrymen engaged in work in India, an overmastering energy which sniffed the air of enterprise, faced difficulties, and threw all the physical and mental energies of the worker into his own field of action. The Himalayas called to Mr. Freshfield to penetrate their recesses and overcome all obstacles, as the deserts of Sind called to the irrigation officer to turn sands into gardens, or famine challenged the relief officer to save his fellow subjects at all cost, or the administration of justice and the promotion of the welfare of millions appealed to the civilian to live laborious days and reap the great reward of duty done in a vast field of activity. It was just the same essentially Anglo-Indian spirit which induced so eminent a climber as the author of the paper to scale heights few Europeans had attempted to reach, and solve, in the interests of science and geography, some of the great problems of nature. One civilian, Mr. A. B. Carey, who had received the highest reward of the Geographical Society, had felt the same call to penetrate the secrets of the Himalayas, and he approached the subject from the same standpoint. Having taken up the challenge, he proceeded on short privilege leave to England, and fresh from his voyage and the heats of the Red Sea, stepped aside for a few hours on his journey from Marseilles, walked straight up and down the Matterhorn, immediately resuming his journey home; and on the strength of that unique and solitary experience of the Alps he returned to India to spend his next long leave in crossing the Himalayas into China. Mr. Freshfield's experiences, in the second place, were those of most Anglo-Indians. As soon as he began to overcome difficulties, and entered the abode of eternal snow, he was told that the gods of the mountains would be offended; and that he could only advance by running counter to the superstitions and beliefs of the native inhabitants of those regions. His footsteps upon the pure untrodden snows were in fact regarded as a desecration. Every public official in India, from the West, had to encounter the same risk, and do his duty at the cost of giving similar offence. The Chairman recollected that when he was taking up land to form the bed of the great Bhatghar reservoir, the priests refused to allow a small temple to be acquired, and insisted that the impious acquirer of these sites would be stricken with disease and death by the offended gods. In fact, at that time, every effort to move the temple elsewhere, or to acquire it at a price, failed. In abolishing slavery and suttee, in opening schools to all castes without distinction, in punishing breakers of the law, without respect for caste, and even in admitting all travellers into our railway carriages, Western systems still daily offended against Eastern ideas. Happily, Mr. Freshfield had found the consolation which his impious intrusion into the secret places of nature brought to him. He had felt and shown to the natives that their fears were really groundless. Even the gods of the eternal mountains had not resented his intrusion. He descended from the roof of the world with more piety, more sense of the "divine architecture," and a deeper "spiritual attraction" than he took with him from the sea-level. That also was the experience of the Anglo-Indian who constantly incurring the "patient deep disdain" of the East, and offending the natives' susceptibilities in the discharge of his duties, was at length rewarded by their appreciation of his work and altered mind towards him. The contrast of the Eastern and Western minds was further illustrated by the history of Sikkim, to which the author had referred. We associated the mountains with the voice of freedom and ability. But the Lepchas of Sikkim had known little else than slavery and forced labour. When Hooker and Campbell were taken prisoners in 1849 by the Rajah Minister, an attempt was made to force the British company to recognise slavery, and restore runaway slaves to their masters in Sikkim. Isolation, and not liberty, was the spirit that reigned on the road to Tibet. Whether the passes which the author had shown on the slides would become highways of commerce, the Chairman would not prophesy, but he joined heartily with Mr. Freshfield in the hope that geographical knowledge had been increased by the late expedition, and that in due course the Government of Nepal would welcome alpine and other artistic tourists to its mountain peaks.

Mr. J. D. REES, C.I.E., said he did not propose to follow the author over "The sky neighbouring mountains of milk snow," or to trench upon politics, which the Chairman had wisely kept aloof from. He only wished to refer to one matter. Mr. Freshfield had told them that in former times a Chinese army had come over into Tibet, and he had said what the Chinese had done in former times they could do again, and so could Russia. Russia was very much occupied, and nobody would be likely to think that it was going to bring an army over that way; but at the present moment it did seem to him that there was such a disposition to take seriously that absurd bogey the yellow terror that he really hoped the author would explain that he did not mean that the Chinese might be expected any moment to go into Nepal or Tibet. Quite recently he had heard Baron Suymatso give a very interesting lecture upon the relations between China and Japan, and he pointed out that those two countries were absolutely antagonistic to each other; that the Chinese never could combine to attack a Western country, and that their sole desire was to keep away from Western countries. Those things were probably known to all present, but there was such a dispo-

sition, dressed up by the Russians for public consumption, to take that bogey seriously, that he hoped Mr. Freshfield would explain that there was no prospect of a Chinese or Chinese-Japanese invasion of Tibet. It was worthy of notice because at that lecture Baron Suymatso's remarks were received in silence, which, as Sir West Ridgeway remarked, gave consent; but at a time like the present, when the bogey views were put seriously forward, it was perhaps worth while for some one in authority to repudiate them. The author had said nothing about gold in his paper, which was to be found, he believed, in Tibet in large quantities. He had referred to the depraved taste of the Tibetans in taking butter in their tea, and he might have mentioned that the Indian tea planters were quite capable of furnishing a rough leaf of that class which was very suitable for taking with butter, as well as of producing the more delicate tea which was consumed in this country with such pleasure. He hoped that steps would be taken to introduce Indian tea into Tibet, in the same way as when our rivals in the East obtained any influence in a country, they used it for the introduction of the products of their industries. It would be very presumptuous of him to criticise anything that had been said by their eloquent and able Chairman, but he was bound to say in all seriousness, that he (the speaker) believed it was unnecessary for every Anglo-Indian to offend the susceptibilities of the natives. There were very difficult cases sometimes, no doubt, such as the taking of the temple without payment, to which Sir William had referred, in order to make a water supply that would save many lives; but he thought the Chairman had spoken with some picturesqueness, at any rate, when he laid down his doctrine on the point. For his own part, he believed that it was perfectly possible to live in India for many years, and not offend the susceptibilities of their fellow countrymen.

Mr. Freshfield, in reply, said he must thank the Chairman for the very kind manner in which he had welcomed him into the noble society of Anglo-Indians. He would like to say that the most vivid impression made on his mind in India was the magnificent service which Englishmen were doing for civilisation, and the happiness of the millions of that country. He saw India under exceptional circumstances, for it was at the time of the famine. The way in which Englishmen tried to save the unfortunate natives was something more than devotion; it was heroism. The feeling that he came back with was that one of the noblest careers in the world was that of an Anglo-Indian. With regard to his having offended the susceptibilities of the natives by his travels, he would remind his audience that there were two theories put forward. One was that the destruction wrought to Darjeeling was due to his offending mountain deities. The other was that the military commander there had fired cannon on a sacred hill. In the end the military commander was held to be the guilty person. The natives who accompanied him on his journey were not dissatisfied, and they told one of his companions that they were ready at any time to go again with the mad Englishmen who liked to build villages in the snow, because they were treated well. With regard to gold, he did not mention it because he knew nothing about it. With regard to tea, he had made his remarks about the difficulty of getting it from India, because he was lately talking to Major Le Mesurier, who had been Commissioner at Leh, and he said the great difficulty was that the English tea merchants had not learnt how to make tea to suit the taste of the Tibetans, and he added that he had written so many reports on the subject that he was thoroughly sick of it. With regard to China and the "yellow peril," he wished once for all in the most emphatic terms to say he had not the slightest fear of it. If Mr. Rees would look at the pamphlet he held in his hands by Dr. Wegener he would see why they might be afraid of China as an instrument in the hands of Russia. If Russia did not send troops, she might send officers to drill Tibetan troops; and to have any hostile force within 400 miles of Calcutta would be highly inconvenient. Moreover, every Indian official would agree that hostile intrigues in Nepal and Bhutan would be very disagreeable to the Government of India. That was the point of view from which he thought English influence should be paramount in Tibet. He thanked his audience for the extreme courtesy and patience with which they had listened to him.

The Chairman said he should like to add one personal remark. When he said they offended the susceptibilities of the natives and that this conflict was inevitable, he had added that he hoped they would eventually come to see that the English were right. As a poet had said—

> "The East bow'd low before the blast,
> In patient, deep disdain;
> She let the legions thunder past,
> And plunged in thought again."

And that was to some extent still the present state of affairs.

A cordial vote of thanks was passed to Mr. Freshfield for his interesting paper.

EIGHTH ORDINARY MEETING.

Wednesday, February 1, 1905; Sir Robert Hanbury Brown, K.C.M.G., in the chair.

The following candidates were proposed for election as members of the Society:—

Ahrlé, F. H. C., 82, Cavendish-road, Harringay, N.

Basden, Rev. George Thomas, B.A., Church Missionary Society, Onitsha, Southern Nigeria, West Africa, and 112, Caversham-road, Reading, Berks.

Black, Captain John Cameron, A.M.I.N.A., The Scottish Shipmasters' and Officers' Association, 128, Hope-street, Glasgow.

Doe, Austin, 42, Claremont-road, Forest-gate, Essex.

Gyles, Nathan, 8, Young-street, Doncaster, Yorkshire.

Hasluck, Paul N., "Ebor," Redhill, Surrey.

Heath, Henry, 2, St. Swithin-street, Worcester.

Kelly, Major Arthur D. D., Weston, Duleek, Co. Meath, Ireland.

Leggatt, Mrs. E. O., 15, Savoy-court, Strand, W.C.

Macfadyen, John Beith, 65, Apollo-street, Bombay, India.

Mackenzie, Alexander, 19, Greenhill-gardens, Edinburgh.

Robertson, Duncan, Forres-park, Trinidad, West Indies.

Skinner, George, A.M.I.Mech.E., 19, Russell-street, Bolton.

Smith, Vincent, Sheffield-road, Chesterfield.

The following candidates were balloted for and duly elected members of the Society:—

Abrams, Herbert John Sinclair, Hutton Mount, Pattison-road, Child's-hill, N.W.

Adams, Alfred Adam, 16 and 17, Devonshire-square, E.C.

Bevan, William, A.R.I.B.A., Chief Government Architect, Public Works Department (P.O. Box 398), Government Buildings, Pretoria, South Africa.

Erikson, Anthony, Assoc.I.N.A., 20, Hummum-street, Fort, Bombay, India.

Evans, Captain Thomas Luther, 59, Broad-street, Bristol.

Fernandez, George Anthony, 43, Raffle's-place, Singapore, Straits Settlements.

Frick, Henry Edgeworth, care of Fore River Shipbuilding Company, Quincy, Massachusetts, U.S.A.

Harwin, Albert Edward, Church-street, Pietermaritzburg, Natal, South Africa.

Hoare, Frederick, 251-254, High Holborn, W.C.

Hynd, John, Consolidated Goldfields of South Africa, Ltd. (Box 67), Bulawayo, Rhodesia, South Africa.

Kelly, John Forrest, Ph.D., Pittsfield, Massachusetts, U.S.A.

Kerr, David Gillespie, The Canada Corundum Company, Ltd., Craigmont, Ontario, Canada.

Khras, Minocher Jamshed Sohrab, Khras Bungalow, Middle Colaba, Bombay, India.

Kingston, C. Burrard, M.Inst.M.M., The Evancon Gold Mining Company, Ltd., Verrés, Val d'Aosta, Italy.

Landau, Miss Dorothea, 30, Bryanston-square, W.

Legarda, Vicente L., 208, Mason street, San Francisco, California, U.S A.

Morris, Rev. E. C., D.D., Ph.D., Helena, Arkansas, U.S.A.

Morrison, Charles, 53, Coleman-street, E.C.

Muir, David Temple, Pentlands, Castlebar-road, Ealing, W.

Oliveri, Joseph Giammusso, A.R.S.M., A.I.E.E., Caltanissetta, Sicily.

Pain, Robert Tucker, J.P., Ryll-court, Exmouth.

Pollock, George Frederick, Hanworth, Middlesex.

Reid, William Lewis, 160, Green-lanes, Clissold-park, N.

Roberts, Cyril, 1, Rossetti Studios, Flood-street, Chelsea, S.W.

Roberts, Richard Penberth, M.Inst.MM., Concession de Tama, Vezzani, Corsica, France.

Robertson, James Barr, The Oriental Club, Hanover-square, W.

Schäfer, Henry Thomas, 40, Brewer-street, Golden-square, W.

Suratwállá, Dr. Ardeshir Bamanjee, Chira Bazar, Bombay, India.

Thomas, Hon. J. J., M.L.C., J.P., Wilberforce-house, Sierra Leone, West Africa.

Trevett, Charles G., A.M.I.E.E., Messrs. Green and Trevett, 15, Castle-street, Cape Town, South Africa.

Tully, John Collingwood, F.R.I.B.A., Ardernes-chambers, Longmarket-street, Cape Town, South Africa.

Wecksley, Felix S., Bangalore, India.

Wedlake, George, Royston, St. Margaret-at-Cliffe, Kent.

Wright, Allister MacLean, 62, Harman-street, Addington, Christchurch, New Zealand.

The CHAIRMAN said it was a peculiar proceeding for one who was a stranger to have to introduce the audience to the Vice-President of the Society, but if they would understand the expression "introduce" in its Pickwickian sense he thought the term would apply. With regard to the subject of the paper, he was well qualified to introduce it in its ordinary sense, because for nineteen years he had had an intimate connection with the navigation of the Nile, and had constituted himself, to some extent, the champion of the boats when the railway administration sat upon them.

The paper read was—

THE NAVIGATION OF THE NILE.

By SIR WILLIAM H. PREECE, K.C.B., F.R.S.

It will be seen from the map that the Nile is fed by four distinct catchment areas:—

1. The Southern Equatorial region that drains into Lake Albert Edward, and, flowing through the Semliki River and Lake Albert, joins the Victoria Nile at the North end of this latter lake.

2. The Southern Equatorial region that drains into Lake Victoria, and issuing from that inland sea forms the Victoria Nile, which, joining the discharge of Lake Albert, forms the Bahr-el-Gebel, and joins the White Nile at Lake No.

3. The North Equatorial region that drains into the Bahr-el-Ghazal, and forms Lake No.

4. The mountainous region of Abyssinia that drains into Lake Tsana, and feeds the rivers Blue Nile, Sobat, and Atbara.

From the Atbara to the sea there is no other tributary whatever, and from Khartoum, where the Blue and White Nile meet, to the Mediterranean this great waterway bears its historical name, "the Nile."*

The quantity of water that passes Berber, a few miles north of the mouth of the Atbara, is but a small fraction of that which has fallen as rain or melted from snow in those vast areas that form its sources. Much supports vegetation, much is infiltrated into the ground, but much more is evaporated away by the fierce heat of the tropical sun to form cloud mist and invisible moisture. Certainly 90 per cent. of this water irretrievably disappears as vapour and never enters the Nile. One of the chief duties of the engineer is to recover some of this lost agent, and to endeavour to utilise it for the benefit and comfort of the cheerful, contented, and ancient population of the Nile Valley. The utilisation of this remnant for irrigation, fertilisation, cultivation, and domestic use, is in the hands of the most competent men in the world, who have not only the practice of 4,500 years before their eyes to study, but the experience of our great Indian dependency to follow, and the lessons of the Mississippi, the Danube, the Po, and other rivers, to mark and learn. There is much in these examples to follow, and more to avoid; but, first of all, there is one great deduction to make from the study of the past, and the observation of the present:—Nature as a rule rebels against hasty or careless interference with her ways, but she is generous to those who study her laws, follow her dictates, and apply her own operations with wisdom, caution, and common sense to aid the wants, comfort, and peaceful purposes of man.

The Nile is virtually embanked from Aswân to the sea. It is practically a canal, and should be treated as a canal. Its principal danger arises from floods, when the rainfall exceeds the average. Floods produce varying currents, and currents may become so strong that by sheer erosion they breach the banks and inundate the country at the wrong time. A high flood means that the river has risen one metre above the land in Upper Egypt, two metres in middle Egypt, and three and a half metres in the Delta. Breaches which at one time were common, are fortunately now rare. The Rosetta branch has not been breached for forty-two years.

The river is controlled by weirs, barrages, and dams. A *weir* is a submerged dam, used to raise the level of the water, so as to force or send it down a canal or the headrace of a millstream for power purposes. The modern term *barrage* is taken from the French, and implies the use of moveable gates in the openings. A *dam* is a weir provided with *sluices* fitted with controllable gates, which enables the level of the water behind it to be raised and regulated for the various purposes. The latest—the Aswân dam—is unique in this, that it can allow the whole flood of the river to pass through without check, and that it is put in operation only when the water has become practically clear of silt.

It is my purpose in this paper to deal principally with the question of the navigation of the Nile from Aswân to the sea, that is, the regulation of its currents, depth of water, channels, and banks, so that the motion of boats shall be possible in all times and seasons both up and down stream. Navigation is a question to which I have devoted a great deal of attention during the past fifty years of my practice as a submarine cable engineer. There are few parts of our coast, channels, firths, and rivers, that I do not know well. I have inspected the Mississippi, the Danube, the Rhine, the Po, and the Nile, and I am an active member of a committee dealing with the navigation of that extremely intricate and shifting channel, the Menai Straits, where many of the points I am going to discuss are vexed questions.

Egypt has always been a country of plenty and of famine, not alone in corn but in water. The Nile is unique in the strange periodicity of its water supply. Its annual rise and fall are most regular, but there are other periodical disturbances, not so regular nor so well known, which, according to Captain Lyons, R.E., the head of the Survey Department in Egypt, are associated with the meteorological vagaries of the Indian Ocean. These produce those high and low Niles which determined the seven years periods of plenty and dearth that wer

* The map of the Nile here referred to will be issued as a Supplement to the next week's number of the *Journal*.

recorded long before the day of Joseph, but which are now fortunately of longer periods.

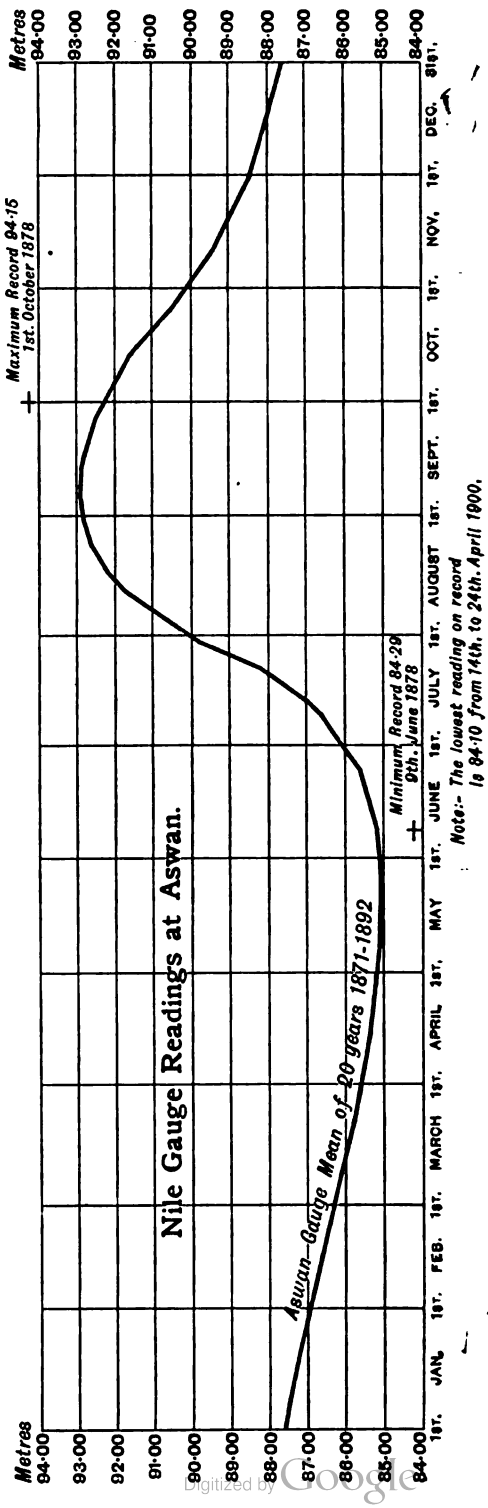
Only a small fraction of the water of the Nile that falls in its catchment basins passes Aswân. Fig. 1 gives the mean of the gauge readings at Aswân for the twenty years, 1871 to 1900. The low Nile is generally in the middle of May, and the high Nile always in the beginning of September. The lowest reading there on record is 84·10 metres in 1900 above the mean level of the Mediterranean Sea. The highest reading was in 1878, when the level recorded 94·15 metres above the sea. The range of the flood was thus 10·5 metres.

The metrical system of measurement is in use in Egypt, and for hydraulic purposes it gives us a very convenient standard—the cubic metre of water. This weighs 2,204 British pounds—very nearly our ton, and exactly the metrical *tonne*. If it were possible to agree with France on the adoption of a standard ton —say, a mean of 2,222 lbs.—we could make the metre a whole multiple of the inch, and all difficulties of the conversion of the one system to the other would vanish. The practical difficulty that confronts us now is the fact that the inch is an unworkable fraction of the metre. Make the metre equal to 40 British inches, and all troubles would cease.*

We are troubled at the outset with the fact that meteorological observations in Egypt have not been continuous or general. Nile-gauges at Roda Island (Cairo) and Aswân have existed, and their indications have been more or less noted for many centuries, but rain-gauges are quite modern. There are now many Nile-gauges and rain-gauges fixed under the observation of the extremely well-organised Survey Department at Aswân, Wadi Halfa, Khartoum, Dueim, Wad Medani, Gondokoro, and Jinja (Lake Victoria). They are sure to supply reliable facts in the future, as, indeed, they are doing now.

The Nile-gauge now used is a baulk of teak anchored to the slope of the river bank, and forming with the level of the water an angle o 30°. A scale of metres is marked on the exposed side of the baulk, and the readings, when multiplied by 0·866 (the cosine of 30°), gives the variable height of the water. The upright posts previously used were damaged by

FIG. 1.



* Distances in this paper will be given in kilometres. Approximately, metres are converted into yards by multiplying by 1·1; metres-square into yards-square by multiplying by 1·2; metres-cube into yards-cube by multiplying by 1·3. Kilometres are converted into miles by multiplying by ·62; kilometres-square into miles-square by multiplying by ·386.

boats and by hippopotamuses, and to prevent disturbance of the gauges from such accidents Capt. Lyons designed this form of gauge, which is now the standard pattern used.

The average annual rainfall in the great lake districts is about 50 inches. It falls over an immense area and for short periods. When the rain falls it comes down solid, and is most trying to those who are exposed to it. Even the ants have intelligence enough to build their hills in the shape of an umbrella or toadstool.

Rain-gauges are fixed, in Egypt, at Alexandria, Port Said, Helwân (Cairo), Assiût, Aswân; in the Soudan, at Wadi Halfa, Omdurman, Kassala, in Abyssinia: at Adis Ababa.

Much of the area in the Lake District is volcanic, and subsidence of the land as well as disturbances of the water throws some doubt on the accuracy of the records of the past in these quarters; but the rise and fall of the Nile is dependent solely on this rainfall, and these records are now reliable.

Lake Victoria is nearly the size of Ireland. Its area is 68,000 square kilometres (26,000 square miles). A fraction only of the enormous rainfall, viz., one-thirtieth, passes Aswân, 29 parts disappear by evaporation, absorption (infiltration in the ground), and vegetation, before they reach the White Nile.

The water which falls at the sources takes much time to reach the navigable portion of the river.

	Period of Low Nile.	Period of High Nile.
Lake Victoria to Lake Albert	8 days	8 days
Lake Albert to Lado	5 "	5 "
Lado to Khartoum	36 "	20 "
Khartoum to Aswân	26 "	10 "
Aswân to Cairo............	12 "	5 "
Cairo to the Sea	3 "	2 "
	90 "	50 "

Thus the rain which falls about the equator early in April passes Cairo in June. It is subjected all this time to the intense action of the sun's rays during the day.

A serious difficulty that obstructs the doctor and the engineer in Nile land is the excessive dryness of the air, which aids the sun in exciting such intense evaporation. The intense energy of the sun acting directly and continuously on the great expanse of waters, converts the water into the form of invisible vapour. This is absorbed at once by the dry air. This evaporation is the most potent factor in the water supply of the country. It has to be carefully considered in regulating the flow out of the Aswân Reservoir, and it must have some weight in determining the position of other reservoirs. A shallow tank of one square metre surface is exposed to the sun near the office of Mr. Macdonald, the Engineer in Chief at the Dam, but protected from the wind by its position, and from insects and disturbance by fine wire netting. Readings are taken daily, and the amount of disappearance of water carefully recorded. The mean results for the year 1903 are as follows:—

January ..	3·5 mm.	July	12·0 mm.
February..	4·8 mm.	August....	11·1 mm.
March....	6·0 mm.	September.	7·5 mm.
April	10·0 mm.	October ..	6·3 mm.
May......	10·8 mm.	November .	4·6 mm.
June	11·5 mm.	December .	3·5 mm.
	Mean .... 7·6 mm.		

The mean for the whole year is thus 7·6 mm. of water evaporated away during every day. This implies that in the hot summer months of June and July, when all the water is needed for irrigation and navigation, one third disappears between Aswân and the sea during its flow of 15 days. How much is lost between the Upper Lakes and Aswân? In the Upper Lakes, where equatorial cloud-belts obscure the sky, and the air is more humid, Mr. Dupuis estimates the mean daily loss at 4 mm. In Upper Egypt, according to Sir W. Willcocks, the evaporation has been found by other experimenters to be 7·5 mm. per day in summer. In Lower Egypt, where the humidity is much greater, it is only 3 mm per day in summer. Linant Pasha gave it as 9 mm. throughout the year, while in the Bitter Lakes (sea water) the French engineers gave it as only 4 mm. in summer. At Aswân it is 7·6 mm. throughout the year.

It is clear that more scientific and more extended experiments are needed to determine this most important factor in the commercial asset of Egypt's agricultural wealth.

The loss of water due to evaporation depends primarily on the intensity of the sun's rays, on the surfaces exposed to those rays, and secondarily on the depth of water, on the wind, and perhaps on the rate of flow of water. The factors are, therefore, the clearness of sky, the dryness of the air, the force of the wind, the temperature and direction of the sun's rays, the time of exposure, and the area of surface exposed. The length of the river remains fixed, but the width varies. The broader the river, the greater the evaporation. Thus, as the length of the Nile is fixed, and the quantity

of water that passes the Atbara River all that passes down, the portion of water that passes Cairo would be increased by deepening and narrowing the river. Anything that diminishes the width of the Nile is beneficial to the water supply, for it would check evaporation. Reclamation of land from the river would increase the depth of the river, for by narrowing its breadth it would strengthen the currents flowing, and therefore their scouring action.

Vegetation is another potent factor in determining evaporation. Living trees absorb moisture, which, rising through the fibres of the tree, evaporates away at every leaf and every flower. Sir William Garstin has pointed out that in the vast swamps, covering unknown areas, which line the Bahr-el-Gebel for a great distance between Gondokoro and Lake No, 750 km. in length, 60 per cent. of the water is lost by evaporation, and the higher the flood the greater the loss. The amount of water leaving Lake Albert is 646 tons per second, and that which enters the White Nile only 300 tons per second; the difference is due to tributaries. He proposes to reduce this terrible waste by making a new broad channel from Bor to the mouth of the Sobat, as shown on the map. It will be 340 km. long and big enough to carry 1,000 tons of water per second. This is a bold and desirable proposal.

Nile Mud.

The Nile in August is a river of liquid mud, derived principally from the erosion of Abyssinia. The information available on this fertilising silt in flood is meagre and unreliable. The tons of solid matter which pass through the dam every year are estimated roughly to number 50,000,000. Of these 30,000,000 are lost in the sea, while 20,000,000 only are utilised as manure. Thus, three-fifths of this valuable stuff is lost.

Silt in Suspension.*

	Gramme per m³.		Gramme per m³.
January	167	August	1,492

May	47	December....	289
June	69		——
July	173	Total ..	3,752

Mean 313 gr. per m³.
Total in year = 49,573,000 tons.

* *Cf.* Baker, "The River Nile." Min. Proc. Inst. Civ. Eng. lx., 1880, p. 367 (376), and taken June, 1874—May, 1875. 1874 was an exceptionally high flood. Copied from "Morphologie der Endoberflache." Penck. I., p. 301.

Careful scientific experiments are very much needed to determine more accurately than we know at present the laws determining the rate of deposition of silt and its variation with the velocity of water. Excellent experiments have been made on the settlement of sand in sea water, but Nile mud is *sui generis*. It consists of matter held in suspension in various sizes from those very fine particles which, on approaching the mouths of the Nile, give the water the green effect called *Eau du Nile*, to the heavier forms which, through the reduction of the velocity of the water, fall and form deposits of clean silver sand that appear as sand banks as we ascend the river. It is only when the muddy water is stagnant and evaporates away that the whole sediment is deposited. The heavier matter, that is the larger particles, fall and are deposited first, while the finest remain to the last, and this natural sifting process is simply a question of the rate of flow of the water. It thus follows that the strength of the currents, the diversion of the water over the land, and its evaporation are such important factors in the successful irrigation of the Nile Valley.

It would appear from Sir W. Willcocks's experiments on canals, that there is no deposit of mud when the velocity exceeds ·7 metres per second (one and a half miles per hour), but as this speed diminishes so does the rate of settlement increase. On the other hand, if the velocity increases to three or four metres per second, as it does in unregulated canals, the water scours away the already deposited matter. This was cured by maintaining a constant current of about one metre per second (two miles per hour). . .

This is what is wanted in the Nile. The principal problem to be solved is how to maintain its own current at a greater velocity than that which causes settlement, and so maintain the depth of the river, and how to prevent the increase of this velocity so as to save the erosion of the banks.

The Aswân dam has shown how to do it, and the Wadi Rayan appears to be an eligible depression to enable a second reservoir of the same storage capacity to be installed. It is a matter under discussion, and serious objections, geological and financial, have been urged against its adoption; but let us hope that these objections will disappear under careful scrutiny and survey, for no more eligible position could possibly be secured for such a desirable scheme to supplement the

Aswân reservoir, since it would reduce the evaporation difficulty to a minimum.

The silt which is carried into the sea and lost there is due, not only to the sources of the Nile, but to the erosion of its banks. This increases with the velocity of the water sweeping past banks that have been cut to pieces by Shadûfs—those ancient water-lifters so prominent in Upper Egypt, but are absent where perennial irrigation has been introduced. [Shadûfs and Sakias are shown by slides.] It would seem from present statistics that the mass of solid matter held in suspension passing Cairo is virtually the same as that passing Aswân, from which it follows, if true, that erosion supplies as much solid matter as irrigation utilises. This is also shown by the fact, which I have myself noticed, and every one who uses a bath on the Nile steamers must find the same, that while the water is quite clear at Aswân, it is thick at Cairo. Indeed, no one can pass down the Nile at this time of the year (January) without being forcibly struck by the destruction of the banks. The reduction of the acreage of the river from this cause is called *akl-el-bahr*—"the eating of the river"—and it is admitted by the Government as an excuse for the reduction of taxation.

A careful examination of the splendid maps which are now being issued by the Survey Department of the Nile Valley, shows clearly the immense loss of energy and of matter there has been in the past through the friction of the liquid mud (for at times the Nile is nothing else) against the friable banks, and the absence of any means to restrain or reduce it. Every bend, every bank, and every backwater is a silent witness to what has been going on from time immemorial. (A section of the river from Aswân downwards placed on the wall illustrates this.)

Although a great many borings have been made to determine the thickness of the alluvium of the Nile, they do not teach us very much. Samples of these borings are to be seen in the Public Works Museum in Cairo. They show that the original floor of the valley was very uneven, and there may have been a deep inroad of the sea even up to the Fayum, some say as far as Esneh. We have not sufficient information at present to frame even a theory. We want a series of bores in lines across the valley at fixed intervals on carefully selected sites. The present rate of deposit is about 0·12 metre per century. If this has been going on for 4,000 years it means a rise of the river bed of 4·8 metres. There may also be a rise of the valley floor. We have no history of the change of slope, but the slope is certainly diminishing, the current of the river is slackening, and the rate of deposit is increasing, and there is trouble ahead if these questions are not tackled seriously and scientifically.

A vital point affecting the industry of the country is the navigation of the river, and the regulation of its depths, channels, and currents.

The influence which the Dam is to exert on the navigation of the Nile has received scant attention up to the present, as far as I have been able to judge. It was designed and intended to further the irrigation of the country. It has, however, a very important bearing on this interesting branch of the subject.

The construction of splendid locks, shown on the screen, has rendered the navigation of the First Cataract perennial, and this must be an inestimable advantage to the population upon the upper reaches of the river north of Wadi Halfa. I purpose, however, to refer to the portion of the river from Aswân to Cairo, apart altogether from the protection from floods, which are well in hand. Here the hindrances to navigation are the want of water at low Nile, the strong currents at full Nile, the closing of bridges, the incessant changes of the channel, the formation of shoals and banks, the constant deposition of matter in the wrong place, and the silting up of the river. With a variable flow of water, an increasing width of river, and a variable channel there must be constant changes of current in direction and strength. Where the river broadens, the speed must slacken, and the silt must fall, and thus we have the incessant formation of islands and banks. The river cannot be ascended without the constant use of the sounding rod, while the Arab pilot seems to have an instinctive knowledge of changes in the channel by the changes in the currents and the appearance of the surface. The Nile has one inestimable advantage beyond the control of man—the persistent north wind. This was appreciated so much by the ancient Egyptians that it was deified and symbolised by them as a beneficent power. The river is the main artery of the life and commerce of the country. All important towns and villages cluster on its banks. It is one brilliant scene of white-winged dahabiehs, gaiassas, markebs, and filukas, laden with human beings, agricultural produce, and manufactured goods. The stately steamer plies with its complement of sight-seeing, peering, restless tourists, and the mail steamers and express boats maintain a regular

service of postal and commercial communication. The number of boats of all classes exceeds 22,000.

I have seen no evidence whatever of any engineering operations in hand, either to maintain the depth or to train the currents so as to keep the channels in their proper course. I have not even seen a dredger at work, but my line of inspection has been confined to Upper Egypt. On the other hand, the destruction of the banks by the Shadûfs is only too apparent.

There are no charts of the river, nor is there any systematic survey in hand. I doubt if any other river in the world is so badly treated. The owners of 22,000 boats would surely submit to a small taxation of £1 per boat per annum to secure better information than they have now, and some attempt at buoying, marking, and beaconing channels.

The Americans have fully recognised the necessity of dealing with obstructions and floods. The Mississippi is virtually a canal from St. Louis to New Orleans. The banks are pitched at a very low angle by what are locally called "levees." They not only meet the case of floods, but they maintain the river in one channel, with navigable depths and with regulated currents. The outlets of the river to the sea have been opened by dredging.

The works which appear to me to be required to improve the navigation of the Nile are:—

1. The removal of obstructive banks and shoals. It has been found in the Severn that the removal of shoals (submerged banks) and the deepening the bed of the river by dredging has led to a marked increase in the flood discharging power of the river. The navigation has also been greatly improved.

2. The river banks in certain places where they are subject to erosion want to be well pitched to prevent this erosion, and to maintain the proper direction of the current. An admirable system of pitching is to be seen near the landing stage at Asyût.

3. Quays want to be built at all towns where commerce is active, goods are landed, and passengers embark and disembark.

4. Shadûfs and Sakias require to be abolished, especially the former.

5. Training walls are needed to direct currents in useful directions. The following conclusion was adopted by the 7th International Congress of Navigation at Washington in 1898:—

"The increase of depth effected by dredging, combined with the rectification of the banks, may, under certain circumstances in the condition of the régime of a river, furnish a satisfactory solution, as shown by the results obtained upon the Severn in England."

6. New lands want to be developed by the deposit of the silt and by the dredging of the river on reclaimed banks and places.

It must not be forgotten that Nature has placed at the disposal of man certain useful working tools which he ought to work for his own advantage, and not, as is too often the case, neglect to his disadvantage.

These tools are:—

Erosion.—The scouring and polishing action of matter suspended in moving water. This depends on the quantity and weight of matter in suspension, and on the velocity with which it moves. Wind is also a powerful force when carrying sand. The action of the sand blast is very evident on every exposed rock. I have seen rocks in the desert rounded by the sand blast like the *roches moutonnées* left by the grinding glacier in the Ice Age.

Potholing.—But the most evident and powerful tool is potholing. Nowhere is this more evident than round and about the rocks at Aswân. There is one just opposite the Cataract Hotel, and close to the old Nilometer, which is still in use as the standard directing the operations of the engineers at the dam. This pothole looks like a comfortable arm chair, such as those used by hall porters in the seats of the mighty; but its seat is of Nile mud, mixed with stones, pebbles, and sand. It is 8 ft. 1 in. from the seat to the top of the back, and 6 ft. 6 in. across the seat.

The rocks are full of these holes. [I show several slides.] I went inside several and measured them. They are of all sizes, from 1 inch in diameter to 12 feet. The size depends probably on the size of the stone that commences the grinding, and the more rapidly it rotates the more rapidly is the hole made. There is no evidence of this rate of working. The grinder must be of harder material than the rock holed. Several have their stones inside them, and also water, but most have pebbles, silt, and sand. Many, like the arm chair, have a side broken off, and many are pierced through. Many are destroyed by weakness or rotten spots. They look for all the world like great pieces of black wood pierced by gigantic teredos. One had the grinding piece of diorite standing out. (Shown in Fig. 2.) The hole was full of deposit of sand and mud. I could not move

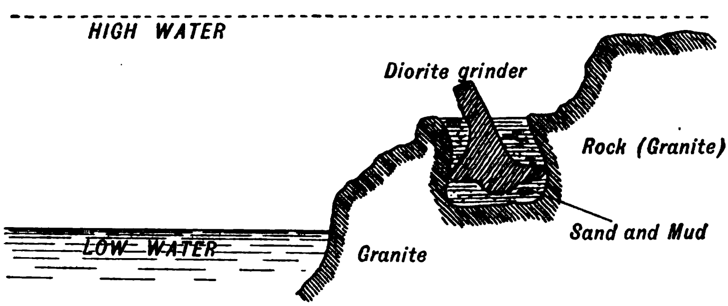
the grinder. This destructive action of "potholing" is very manifest.

There are two spots on the river—the one 1 km. above, and the other 2½ km. below the dam, where holes or pools of 40 metres depth have at some early period been scoured out by falling water. These show that waterfalls once existed here, and that the much-doubted statements of Diodorus Siculus and of Herodotus of the roar of the cataracts were probably quite true. The obstacles which caused them must have been removed by potholing. There are clear marks of a higher level of the river above the site of these falls. The same kind of thing is found at Semneh, above Wadi Halfa.

The following facts apply to Aswân. The distance from Aswân to Cairo is 900 km., and to the sea 1,262 km. The slope of the river is:—In the First Cataract, 1 in 1,000; between Aswân and Cairo, full Nile, 1 in 10,800; low Nile, 1 in 13,000. The mean velocity of the water is:—In full Nile, 2 to 1 metres per second; low Nile, ·7 to ·3 metres per second.

The current in the Nile ought not to exceed 2 metres per second, or to be less than ·7 metres per second; the former to prevent the stoppage of the ascent of the river by boats, and the latter to prevent deposition of silt. The mean width of the river is now 900 metres. The flow of water is:—In full Nile, maximum, 13,200 tons per second; minimum, 6,500 tons per second; mean, 10,000 tons per second. In low Nile, maximum, 1,300 tons per second; minimum, 210 tons per second; mean, 410 tons per second. The reservoir at Aswân has increased this minimum to 410, and the mean to 755. The reduced water level—that is, the height above the mean sea level—is:—Full Nile, 93 metres; low Nile, 85 metres; the mean range difference between the two being 8 metres.

FIG. 2.—POTHOLE.



The Aswân dam was designed to hold up water to the level of 106 metres, so as to store up 1,000,000,000 tons of water, but it is found strong enough to hold up 107·05 metres. It is now intended to raise it so as to hold up 112 metres, and this will enable it to store up 2,000,000,000 tons of water. This is a "consummation devoutly to be wished," and a fitting crowning of this great work.

There are two other great works in contemplation, and probably by this time authorised. The one is the opening of the new channel from Bor to the Sobat river, so as to shunt away the Bahr-el-Gebel with its "Sudd" obstructions and its wasteful swamps. "Sudd" is a collection of papyrus and other reeds, swimming plants, "Bus" and "Umsoof" (mother of cotton) roots and stems, so compact and firm as to be impenetrable and able to hold up the water. Its depth varies from 2 to 6 metres and its length is often measured in kilometres. The Bahr-el-Gebel was impassable owing to these obstacles. The longest obstacle was 36 kilometres, the next 12 kilometres, and the others varied from 2 kilometres to 600 metres. They were removed by cutting the surface into rectangular blocks, hauling these out by steamers, and letting them float away down stream. They disappeared by disintegration. The second is the improvement of the Rosetta and Damietta branches in the Delta, so that the former can carry away to the sea the dangerous flood waters, and the other maintain the navigation and irrigation of that part of the country. Other works of canals and drains must necessarily follow these great works proposed ultimately, but in the mean time in Upper Egypt 750,000 acres of basin land must be converted into perennial irrigation, and this will make historical, I hope, the Shadûf on the Nile.

The improvement of the navigation of the Nile will benefit a large community, and it is a question whether the cost of the perpetual opening of the river should not be paid for by those who would profit so largely by it.

Since 7 mm. is the mean daily loss of water due to evaporation, every square metre must lose a ton of water in every 143 days, and, therefore, 2½ tons of water per annum escape from every square metre exposed. Now, a feddan of land means roughly 4,000 square metres, and, if reclaimed from the river, it practically adds to the river 10,000 tons of water per annum to sustain the current and to diminish the call made upon the reservoir at Aswân for water during low Nile. It is pure gain, for it diminishes the surface and adds to the depth. It also adds one feddan to the cultivable land for the growth of crops, and, therefore, it adds to the wealth of the country. The reclamation of land from the river is thus a pure commercial advantage as well as a prudent and political measure for the benefit of the navigation and the maintenance of the river. There are many places on the river where this could apparently be very easily, if not profitably, carried out. Aswân itself is one. Such a growing place and favourite health resort wants a proper quay, with landing-places along its river front, and a well-equipped market for its imported produce. There is a great sweep of waste land on the east side, covered by flood and exposed in low water, which could be reclaimed by a revetment in front of the town and a levee, and which would add many feddans to the land and supply many thousands of tons of water to the river. There are many other places on the river where this could be done. Is it worth while, and does it come within practical politics?

The Aswân reservoir extends up the river for 224 km. The mean breadth is 900 metres. This makes the surface roughly 200 square kilometres exposed to the sun's rays for about four hot months. This would cause a loss of 20 per cent. of the water stored. When the water stored is doubled by raising the dam, the surface exposed will not be nearly doubled and therefore the ratio of loss will not be so great. In fact, in these hot countries we should rely more on depth and less on surface when forming reservoirs. The loss in that natural reservoir, Lake Victoria, is 55 per cent. of the water that enters the lake, in Lake Albert 60 per cent. and in Lake Tsana 55·5 per cent. The loss on the river between Lado and the White Nile is 62 per cent. This, as Sir W. Garstin says, "is an appalling waste of water."

The chief point for careful consideration appears to me to be not only the control of the water, but the control of the silt. Thirty thousand tons of valuable mud are lost in the sea every year, and the rise of the bed of the river in the Delta is a very serious question. Navigation is thus checked, but the remedy is at hand. The outlets are to be cleared by dredging. More sediment will be utilised on the land. Currents will be regulated by storage and barrage. Floods will be under better management. But what is most urgently needed is the protection of the banks, the training of the river, its maintenance in well defined limits, a depth navigable in all seasons, and a call on Nature to assist man to regulate this precious water communication for his daily service.

DISCUSSION.

The CHAIRMAN, in opening the discussion, said the author's interesting paper had carried him back to the scenes of his labours extending over a period of nineteen years. He confessed to a certain surprise in the paper, for he had expected to hear something about electricity in connection with the navigation of the Nile, but not a word had been said on the subject. Sir William mentioned the Zifta barrage, and asked him (the Chairman) to describe it; but there were so many pegs upon which to hang a discussion, that he thought he had better decline the invitation, and confine his remarks to the subject of the paper. The author had rightly called the Nile a canal below the Aswân dam. The Aswân dam constituted the head work of the chief canal of Egypt, which was the Nile below it, and the Assiût barrage, the Delta barrage, and the Zifta barrage, were so many regulators on the main canal, while the so-called main canals which took off from above those barrages were really branch canals of the main natural canal. It was a perfectly correct view to consider the Nile below the Aswân dam as a canal, and it should be considered as such. The purpose of the paper he took to be the advocacy, the training of the Nile, with two objects—firstly, to lessen the loss of water which took place by evaporation in consequence of the excessive width of the Nile in its summer channel; and secondly, to improve the navigation conditions by deepening the summer channel so that boats could more easily navigate it. He had had some experience in India of training shallow rivers in summer so that they might preserve a minimum depth suitable to the traffic which had to pass along them. The first thing to be done was to stop all erosion of the banks, and secondly, after the erosion of the banks had been stopped, to narrow the natural channel so that it might deepen itself. Some

years ago a certain amount of money was given to him to make an experiment with that system on the Nile, but it was given so late in the year that it was not of much good. Enough, however, was done to show that if the system were applied to certain reaches on the Nile, and supplied in time, it would be most efficient in producing the effect desired, *i.e.*, deeping the central channel. The experiment was not repeated because it required so much money; and there were so many things in Egypt which required to be done more vital than the Nile navigation, such as irrigation, that the money was spent on them, with the result that the navigation had to wait. Times had now changed; there was more money and more water in the summer time in the Nile, so that for both those reasons it might be found easier to undertake the training of the summer channel, which the author, he imagined, wished to advocate. He thought Sir William was a little hard on the Sakias and Shadûfs, because he did not think they had anything like the destructive effect the author imagined. Sakias and Shadûfs would always be found erected on the stiff clay banks of the river, where the erosion did not take place, because if they were to set themselves up on the curves where erosion was acting energetically, they would soon find themselves in the deep water under the bank; consequently, a place was nearly always selected where the clay was stiff, and the Nile erosion had not much effect. He also thought Sir William was incorrect in saying there were no Shadûfs in Lower Egypt. It was true there were no Shadûfs where there was free-flow irrigation, but where there was perennial irriga-which had to be lifted, Shadûfs would be found in very great numbers, and not a few in the north part of the Delta. The first step in the improvement of the summer channel of the river was to stop erosion, and in that direction the Government had already done a good deal at the worst points. They had made spurs to stop the river encroaching on its banks, not so much with the object of training the river, as for protecting threatened points which it was important to protect, such as the railway and important villages; so that something had been done towards the training of the river by the stopping of the erosion. The training of the river was a very expensive business, which was the reason why it had not been undertaken before. In Lower Egypt it had been decided to take in hand the Damietta and the Rosetta branches, and to protect them thoroughly, so that there would be no danger of the Nile banks ever breaching, and when that was done perhaps more money would be spent in Upper Egypt in the same direction, and a commencement be made with the training of the summer channel of the river. There was only one place at which a deliberate attempt had been made to train the river into a channel in which it would not naturally go, and that was above the Delta barrage. For some years operations had been carried out for the purpose of endeavouring to induce the river to take to channels which would flow on to the barrage in regular lines which were laid down on a map, and which they had been trying to force it to take. He believed that £3,000 a year had been spent on it for something like 15 years, and it was not yet done, and taking that expenditure as a guide to the whole of the river, it would take a large sum of money to carry out the work. The author also mentioned that the foreshores and certain shallow places in the river should be reclaimed from the river so as to protect the channel. A beginning had been made with that work, a concession having been given to the New Egyptian Company, which was advised by Mr. Beresford, a very well-known Indian engineer. Operations had been commenced at a good many sites, but it was necessary to proceed slowly with the work, otherwise a good deal of money might be thrown away in operations which were conducted on a wrong system. The company preferred to profit by the experience of one site before they took up another site; so that in that respect also the Government was doing something.

Mr. R. B. Buckley, C.S.I., said that the question of internal navigation in all countries was one which nowadays was attracting more and more attention, and the author had done good service in drawing attention to the necessity of improving the navigation of the Nile. The Chairman seemed to think that the cost of doing the work might be prohibitive, but other nations were spending very large sums indeed in works of a similar nature, and he therefore hoped Egypt would find the funds which were necessary for mproving her navigation. Egypt had, in one way, given great assistance to the navigation of the Nile by following the lead which other countries had adopted of removing all tolls from boats on navigable rivers. Many years ago in Egypt, when the Government constructed the bridge at Cairo, they put a toll on all boats going through the bridge, and the same system was adopted when a new canal with locks was opened. But the Egyptian Government, under its present enlightened rule, had entirely removed the tolls, and all the navigable canals and rivers were entirely free. He believed that France in the last 30 years had spent £70,000,000 sterling on improving the navigable waterways, which were entirely free of tolls. The American Government had spent nearly a million pounds in improving the navigable rivers which were connected with the great coal centres, and they were also entirely free from tolls. The only country, (as far as he knew, which still charged tolls on Government works was India; while in England the canals were in a state of chaos, under different administrations. The point he wished to emphasise was, that if France, Egypt, and Germany (which had spent 15 or 20 millions on improving her waterways) had free waterways, while in England and India tolls were charged on all the navigable routes, a very great injustice was done to the people of those countries, because they had to

pay more for the carriage of their goods to the seaboard than traders in countries which had free waterways. The only other point to which he wished to refer was the question of the amount of the discharge from the Victoria Nyanza into the Nile. It was stated towards the end of the paper that 45 per cent. of water on the Victoria Nyanza found its way into the Nile. He could not but think there must be some mistake in those figures. Three years ago he visited the Victoria Nyanza, inspected the four or five gauges on the lake, and criticised all the data concerning them. The author gave the rainfall alone on the Victoria Nyanza as 50 inches; he did not think it was quite as much, but the facts were not very well known. The Nile carried, at the outside, from the Victoria Nyanza in the course of a year, an amount of water which might lower the lake nine to twelve inches, which was only equivalent to about one-fifth of the rainfall on the lake. But the rainfall was not all the water that came into the Victoria Nyanza, because about 75 thousand square miles of land round about drained into the lake, so that the proportion of water which actually flowed out of Jinja was considerably less than one-fifth or one-sixth of the water which went into Lake Nyanza. He mentioned the question because the fact was interesting in this connection. There were some present besides himself who could remember when Speke and Grant discovered the Ripon falls close to Jinja. Since then great developments had taken place in Egypt, and one idea which at first sight appealed to one strongly was that the Victoria Nyanza would make an excellent reservoir from which to feed all the lands which required irrigation down the Nile. But when the question was thoroughly examined, the conclusion was arrived at that the amount of water which went out of Jinja on the Ripon falls would be practically powerless in having any effect on the amount of water available for the Nile. The fact was that the water of the Victoria Nyanza did not go into the Nile; it flowed down and all round the Nile, and then came back again; it was constantly passing into the lake and up again by evaporation, so that the great lake, important and interesting as it was, would never serve any great purpose in adding to the summer supply of the Nile.

Mr. ALEXANDER ROGERS said a good deal was written in the newspapers about the obstruction of the Nile caused by sudd. He thought it would be of interest if the author would explain what sudd was, in what part of the river it occurred, and if anything had been done to free the channel from obstruction.

Sir WILLIAM PREECE, in reply, said that the River Nile, from Bor to the White Nile through the marshes, was blocked in many places by sudd, which was composed of papyrus and other reeds, swimming plants of innumerable kinds, a tree that grew with great rapidity, root and branch practically, in the water, called "buzz," and another tree, the Arab name of which was "mother of cotton." Those things grew in one impenetrable mass across the river, blocking it and preventing navigation. The sudd was so dense that it held up the water just as a dam would do. Between Bor and the White Nile there were fifteen or sixteen such obstacles, many of them whose thickness could be measured in metres, many one and two kilometres, one 12 kilometres, and another 36 kilometres. They were from one to two metres deep, going right down to the bottom of the river, and were thus living vegetable dams. But the obstruction had been removed through the skill of an officer of the Royal Engineers. The sudd had been cut into solid blocks, which had been allowed to float down the river, and had disappeared before reaching Aswân. Sudd had been a great difficulty in the past, but it had been entirely removed. He believed the 36 kilometre sudd dam was removed last winter, and that the river was now clear of navigation all the way down to Gondokoro.

On the motion of the CHAIRMAN, a hearty vote of thanks was accorded to the author for his extremely interesting paper, and the meeting terminated.

THE VILLAGE HOUSING PROBLEM.

In the *Journal* of January 17 mention was made of the Humphrey iron cottages as suitable for the purpose of rural housing, and the chairman of Humphreys Limited has been good enough to furnish some particulars. These iron cottages are for various purposes, from shooting boxes in Scotland to bungalows in the Transvaal; but here attention is confined to cottages erected in villages for the use of labourers. Many hundreds of these cottages have been erected in various parts of England, and many more would have been erected but for crippling by-laws. Of course there are many parts of rural England where there are no building by-laws, where a man may build the thing he will so far as any local authority is concerned. But more and more the district councils seem to be invested with urban powers, and the powers asked for are certain to include the right to make by-laws insisting upon "external and party walls of good bricks, stone, or other hard and incombustible material," instead of stud and plaster, or stud and galvanised iron. Herein is the difficulty, the crux of the village housing question. An excellent corrugated iron cottage, ample in size for the requisites of an ordinary village family, can be put up for £150, or less, but the local authority vetoes it. The cottage must be of "brick, stone, or other incombustible material." But why should a wood and galvanised iron cottage, standing on brick footings, on a concreted site, and matchboarded inside, be considered combustible, or more combustible than a

cottage of brick or stone? Why should the local authority object to corrugated iron when a peasant's cottage is in question, and raise no objection to it when a small-pox hospital has to be built? It is possible to put up such buildings for hospitals and asylums because they are exempted from the operation of the building by-laws, and it is noteworthy that over a million sterling has recently been expended by the London County Council, and other local authorities, upon similar buildings.

It is hard to understand how this fire bogey can be relied upon to justify the prohibition of iron cottages. The Chairman of Humphrey's, Limited, says that he can recall no single instance of a wood and iron cottage put up in a village by his company being burnt down, nor could better evidence of the groundlessness of the fear of fire be required then the fact that insurance companies will insure these cottages at 1s. 6d. per £100. The general adoption of the iron cottage would go far to solve the village housing problem. They are cheap, they are durable, and they are comfortable. First as to price. The £150 named above is the maximum. A good cottage of this kind can be put up for £130, but the rent a labourer can afford to pay will give a fair return upon an outlay of £150. Standing on brick footings the cottage should be a single story building, two feet above the ground. The single story lessens cost, saves the housewife much labour, and is healthier. The interior of the rooms being matchboarded, stained, and varnished, there is great cleanliness, as the housewife has only to use a duster of flannel and soap to keep them perfectly clean and wholesome, which cannot be said of cheaply papered or plastered walls. No doubt the building may be over hot in summer if not constructed by an experienced builder, but when an air space between the boarding, felt, and iron is provided for, it should be of an agreeable temperature all the year round. The durability of the iron cottages is very great. In towns the iron rusts, and its life cannot be put at more than twenty years, but in the purer air of the country it is practically indestructible. The allegation that the iron cottages are insanitary has no substance in it. What is there in iron, or varnished boarding, to make them insanitary. The earth closets in the outhouses used with this class of building are much preferable to the usually neglected "privies" left uninterfered with by the Local Authority.

Of course it is not suggested that resort should be had to iron and wood cottages and nothing else. But where, as in the immense majority of cases, new cottages will never be erected unless they can be put up so as to give 4 or 5 per cent. upon the capital outlay, these iron cottages, which can be erected at a cost to give this return, have much to recommend them. It may be hoped that before long means may be found to induce councils to abrogate, or amend, their building by-laws, but, meantime, it is well to remember that an iron and wood building—say a Humphrey's cottage—may be brought within existing by-laws by building a very small part in brickwork that does not add more than 15 per cent. to the cost of the building.

AGRICULTURAL EDUCATION IN CANADA.

Nothing is more remarkable in connection with Colonial development than the way in which the farmers of the Dominion, judiciously assisted by the State and Central Governments, have supported and benefited by agricultural education. Twenty years ago Ontario farmers were in a bad way. Their farms were mortgaged, their lands, owing to bad cropping, were losing their fertility and value, their sons were flocking to the professions, or the United States. Then the Hon. John Dryden became Minister of Agriculture for Ontario, and to him is chiefly due the happy reversal of circumstances in which the farmers of the province find themselves to-day. When Mr. Dryden first became Minister the quality of Canadian cheese and butter was very inferior. He set to work to improve, and, helped by the Government at Ottawa, Canadian dairy produce soon became famous for quality. In the report of the Bureau of Industries for 1889, the opinions of representative Ontario farmers are quoted to show that the Ontario hog raiser could never hope to compete on equal terms against the cheap pig food of the United States. At that time the old idea of a short, fat hog was still in the ascendant, and it was no wonder that the capture of the English bacon market was looked upon as impossible. During the early and middle nineties Mr. Dryden took personally in hand a campaign for improving the quality of the dairy and hog products of the province. He started what was known as the "Travelling Dairy," and kept it going from 1891 to 1898. It made annual tours through the country, and was laughed at as "Dryden's Circus." But it did what it was intended to do. It attracted attention, and thousands of farmers and their wives were taught what may be called scientific dairying. And concurrently the dairymen's associations grew to be powerful organisations for the promotion of new methods. The Government helped with money grants, the securing of good speakers, and the distribution of the reports of the meetings to 30,000 farmers. Two new dairy schools were also opened at Guelph and Strathruy, and that at Kingston was taken over. Since 1903, over 90,000 dols. has been spent in the education of over 2,200 dairy experts. During the last year the work has been extended to include a more minute inspection of factory and farm dairy premises in a way which insures the highest cleanliness, and best quality of cheese and butter.

Nor was improvement confined to dairy products. The hog was taken in hand. Mr. Dryden, backed by the Government, was determined to get a share of

the English market for Canadian bacon, and that was only possible by evolution in the hog. The provincial winter fair, the farmers' institutes, and the distribution of reports and bulletins, was the chosen medium The winter fair was made a fixture in Guelph, permanent buildings were erected, and prizes offered which would tempt the best breeders in the country. This attracted many thousands of the farmers. The pork packers were invited to attend, and by demonstration to tell the crowded audience of the lecture-room just the kind of hogs they wanted. They eagerly acccepted, the farmers' institutes' delegates attended and sized the "points" of a good hog, and how it could be produced by breeding and feeding, and they carried the message to numberless homes. The result was seen in a few years in the supplanting of the short, fat hog by the long lean ones, just the kind that make the streaked bacon and the red, sweet hams suitable to the English market. The remarkable success of this missionary work is shown by the increase in the value of the hogs sold by Ontario farmers from 8,775,852 dols in 1892 to 22,532,892 dols. in 1903.

Doing a work of this class, and yet fitting into the whole general scheme, the farmers' and women's institutes have accomplished much in the uplifting of agriculture. From a record of twelve meetings in 1885 the farmers' institutes have grown, says the *Toronto Globe*, from which many of these particulars are taken, to 837 meetings last year, with an attendance of 126,352, while the women's institutes, established three or four years ago, had last year 960 meetings and an attendance of 44,698. Skilled agriculturists, breeders, and home makers give the lectures at these meetings. Their addresses are the statements of men and women who have derived their knowledge from experience, and in imparting it they give the impression that what they have done others can do. The success of the Ontario live stock competitions at the Pan-American Exposition at Buffalo in 1901 was the best tribute that could be paid to the quality of the stock raised, and the triumphs at St. Louis last year are still fresh in the public recollection.

The improvements effected in the butter, cheese, and bacon products of Ontario are a striking illustration of what can be accomplished by co-operative effort, aided and guided by Governmental supervision. The Eastern Ontario dairymen have just concluded at Brockville their 20th Convention, and the papers and discussions showed the thoroughly scientific and practical methods that have been introduced in every department, from the care and milking of cows to the final shipment and disposal of the butter and cheese. The farmer no longer despises or mistrusts the scientists in the agricultural college or dairy school, but is keen to avail himself of the latest discoveries of scientific research. The statistics of decennial periods show that the output of creameries and cheese factories in the whole of the Dominion increased from 10,697,879 dols. in 1890 to 29 462,402 dols. in 1900. These figures show an increase in ten years of 18,764,523 dols. In 1890 there were 1,565 cheese factories and 170 creameries in Canada. In 1900 there were 2 398 cheese factories and 629 creameries, with 974 combination cheese and butter factories. The conventions periodically held tend to correct any faults that may show themselves, either in the scientific or commercial management of creameries and cheese factories. The best judgment of practical experience and scienti c inquiry is brought to bear on every problem. Every defect is fully ventilated and traced to its immediate and remote causes.

Something is being done in England in these directions, but how little as compared with what is being accomplished in Canada and elsewhere in Greater Britain! And yet it should be much easier to convey the necessary instruction here than in the sparsely-populated provinces of the Dominion. Nor is the need less.

STRAND IMPROVEMENTS.

The following address o the London County Council deals with a subject referred to in the paper on "Street Architecture," read before the Applied Art Section, by Mr. T. G. Jackson, R.A., on 20th December last.

"We, the undersigned, are anxious that the improvement of the Strand should be carried out in a manner worthy of so great an opportunity.

We desire to express our opinion that the frontage line now proposed by the London County Council will have a bad perspective effect, and we trust it may not be too late for the Council to adopt some plan showing better consideration for the position of the churches of St. Mary-le-Strand and St. Clement Danes.

We desire also to protest against the height of the buildings already begun, and to express our hope that on the rest of the frontage the new buildings may not be so lofty as to overpower the two churches and Somerset-house, which are and should remain the principal ornaments of the Strand.

Mr. Jackson sent this address for publication in *The Times* with the following letter to the Editor:—

Sir,—A copy of an address intended to be presented to the London County Council on this subject was sent you the other day for publication without the leave or knowledge of those responsible for it, who would not have been guilty of the discourtesy of publishing it before it had been seen by those to whom it was addressed.

It has now been received by the London County Council, and is under consideration, and I therefore beg to send you a copy with the names of the signatories correctly given, which was not the case in the unauthorised copy sent you before.

The plan now recommended by the Improvements Committee for the new frontage is, as I said in a former letter, the cheapest and worst that has been submitted to the Council. It is laid down on purely economical and utilitarian lines, and the report with which the committee have accompanied their recommendation scouts the idea of attaching any importance to æsthetic considerations. This, I trust, will not be the attitude of the Council as a whole. They have on former occasions listened favourably to representations of an æsthetic character made by persons who from training and habit were justified in speaking with authority. The church of St. Mary-le-Strand, which was condemned to be destroyed, was spared when its value as a work of art was explained. We trust that the present appeal from a large number of artists, among whom will be found most of those who have a claim to be heard on such a subject, will be equally successful.

That art is always to give way to economy when it comes to a question between them will hardly be maintained by the most advanced utilitarians. Were it so, surely we had better confess ourselves at once an inartistic people, shut up our art schools, and save the many hundreds of thousands of pounds we spend in preaching and teaching what in our practice we treat as valueless. Art must be paid for, and cannot be had without some sacrifice; and, if ever a sacrifice were worth while, surely it is so now, if it will save the fine buildings in the Strand from being smothered by monstrous edifices like that next the Gaiety Theatre, which would reduce them to the scale of toys and the Strand to the awful gloom of Victoria-street and the sombre melancholy of Northumberland-avenue.—I am, Sir, your obedient servant,

THOS. G. JACKSON.

Eagle-house, Wimbledon.

OBITUARY.

SIR JOHN NEILSON CUTHBERTSON, LL.D., J P.—Sir John Cuthbertson died on the 26th January at his residence in Glasgow. He was born in 1829, and educated at the High School and University of Glasgow, also at the Royal College, Versailles. He was knighted in 1887, and received the degree of LL.D. from the University of Glasgow in 1895. He was a chemical and produce broker, and one of the best-known public men in Glasgow and the West of Scotland. For 25 years he was a member of the Glasgow School Board, and for 15 of these was the chairman. He was a member of the University Court, Glasgow, and a governor of the Glasgow and West of Scotland Technical College. Sir John Cuthbertson was elected a member of the Society of Arts in 1894.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock:—

FEBRUARY 8.—"Time Development in Photography, and Modern Mechanical Methods of carrying it out." By R. CHILD BAYLEY. GEORGE DAVISON will preside.

FEBRUARY 15.—"The Decline of the Country Town." By ARTHUR HENRY ANDERSON.

FEBRUARY 22.—"Some Misconceptions of Musical Pitch." By JOHN E. BORLAND. (*a*) *Visual*—due to conventional but inaccurate notation; (*b*) *Aural*—volume of tone mistaken for depth, brightness for height.

Illustrated by voices, instruments and diagrams.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

FEBRUARY 16.—"The Indian Census of 1901." By SIR CHARLES A. ELLIOTT, K.C.S.I., LL.B. The RIGHT HON. LORD GEORGE HAMILTON, G.C.S.I., M.P., will preside.

COLONIAL SECTION.

Tuesday afternoons at 4.30 o'clock:—

FEBRUARY 28.—"The Manufactures of Greater Britain.—I. Canada." By C. F. JUST, Canadian Government Service in London.

APPLIED ART SECTION.

Tuesdays, at 4.30 or 8 o'clock:—

FEBRUARY 21, 8 p.m.—"The Queen Victoria Memorial as compared with other Royal Memorials." By MARION H. SPIELMANN, F.S.A. JOHN BELCHER, A.R.A., President of the Royal Institute of British Architects, will preside.

CANTOR LECTURES.

Monday evenings, at 8 o'clock:—

JAMES P. MAGINNIS, Assoc.M.Inst.C.E., M.Inst.Mech.E., "Reservoir, Stylographic and Fountain Pens." Three Lectures.

LECTURE III.—FEBRUARY 6.—*Fountain Pens.*—Early patents—Solid ink—Various reed arrangements — Self-filling reservoirs, flexible reservoirs, piston and plunger—Modern types of Fountain pens, Swan, Ideal, Conklin, Pelican, Unleakable, Wirt, Quill, Post, Autofiller, Fleet, &c.

DUGALD CLERK, M.Inst.C.E., "Internal Combustion Engines." Four Lectures.

LECTURE I.—FEBRUARY 13.—*Fundamental Principles.*—Internal combustion engines are essentially air engines—Thermodynamics of air engines—Two types, constant volume and constant pressure—Theory of compression—Efficiencies without heat or other losses—Gaseous explosions—Temperature measurements—Bunsen's method—Efficiencies with heat and other losses—Coal gas, petrol, alcohol and producer gas explosions: their differences and similarities.—Data still required.

LECTURE II.—FEBRUARY 20.—*Indicator Diagrams and Power Tests*—Diagrams from engines using coal gas, producer gas, blast furnace gas, petrol and heavy oils—Practical efficiencies and limitations in large and small motors for constant volume and constant pressure engines—Brake tests—Irregularities in diagrams, pre-ignitions, back ignitions, exhaust explosions, missed ignitions.

LECTURE III.—FEBRUARY 27.—*Examples of Internal Combustion Engines in Britain.*—Coal gas and producer gas engines, Crossley, National, Stockport—Blast furnace gas engines, Cockerill, Koerting, Crossley, National—Petrol engines, Wolsley, Liddeley, Daimler—Heavy oil engines, Deisel, Hornsby, National, Crossley.

LECTURE IV.—MARCH 6.—*Future Developments* — Suction producers — Blast furnace gas—Producer gas in power-stations—Marine gas and oil engines—Line of advance.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, FEB. 6...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Mr. James P. Maginnis, "Reservoir, Stylographic, and Fountain Pens." (Lecture III.)

Royal Institution, Albemarle-street, W., 5 p.m. General Monthly Meeting.

Engineers, in the Theatre of the United Service Institution, Whitehall, S.W., 7½ p.m. Inaugural Address by the President, Mr. Nicholas J. West.

Chemical Industry (London Section), Burlington-house, W., 8 p.m. 1. Mr. W. P. Dreaper, "The Theory of Dyeing. Part. II.—Pseudo-solution and Desolution." 2. Mr. J. W. Lovibond, "The Fading of Inks and Pigments."

British Architects, 9, Conduit-street, W., 8 p.m. President's Address to Students.

Camera Club, Charing-cross-road, W.C., 8½ p.m.

Medical, 11, Chandos-street, W., 8½ p.m.

Victoria Institute, 8, Adelphi-terrace, W.C., 4½ p.m. 1. Rev. J. Bradford Whiting, "The Growth of the Kingdom of God." 2. Rev. John Tuckwell, "Religion and Science."

London Institution, Finsbury-circus, E.C., 5 p.m., Mr. M. H. Spielmann, "The Wallace Collection."

Society for the Encouragement of Fine Arts, 6½, Suffolk-street, Pall-mall, S.W., 8 p.m. Mr. Pascal Needham, "The Development of Song Writing."

TUESDAY, FEB. 7...Royal Institution, Albemarle-street, W., 5 p.m. Prof. L. C. Miall, "The Structure and Life of Animals." (Lecture IV.)

Alpine Club, 23, Savile-row, W., 8½ p.m.

National Service League, Caxton-hall, Westminster, S.W., 5½ p.m. Lieut.-Col. O. T. Duke, "The Physical Advantages of Universal Naval and Military Training."

Civil Engineers, 25, Great George-street, S.W., 8 p.m. 1. Discussion on Mr. Lyonel Edwin Clark's paper, "Floating Docks." 2. Mr. E. F. C. Trench, "Alfreton Second Tunnel." 3. Mr. Dugald McLellan, "The Reconstruction of Moncrieffe Tunnel,"

Pathological, 20, Hanover-square, W., 8½ p.m.

Zoological, 3, Hanover-square, W., 8½ p.m.

Pharmaceutical, 17, Bloomsbury-square, W.C., 8 p.m.

WEDNESDAY, FEB. 8...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. R. Child Bayley, "Time Development in Photography, and Modern Mechanical Methods of carrying it out."

Biblical Archæology, 37, Great Russell-street, W.C., 4½ p.m.

Royal Literary Fund, 7, Adelphi-terrace, W.C., 3 p.m.

THURSDAY, FEB. 9..Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

Junior Art Workers' Guild, Clifford's-inn-hall, Fleet-street, E.C., 8 p.m.

London Institution, Finsbury-circus, E.C., 6 p.m. Rev. Canon Benham, "The Literary History of the Bible."

Royal Institution, Albemarle-street, W., 5 p.m. Prof. W. Schlich, "Forestry in the British Empire." (Lecture II.)

Electrical Engineers, 25, Great George-street, S.W., 8 p.m. 1. Discussion on paper by Messrs. W. H. Booth and J. B. C. Kershaw, "Fuel Economy in Steam Power Plants." 2. Mr. G. L. Addenbrooke, "The Value of Overhead Mains for Electric Distribution in the United Kingdom."

Mathematical, 22, Albemarle-street, W., 5½ p.m.

Camera Club, Charing-cross-road, W.C., 8½ p.m.

United Service Institution, Whitehall, S.W., 3 p.m. Col. Sir Howard Vincent, "The United States Army of To-day."

FRIDAY, FEB. 10...Royal Institution, Albemarle-street, W., 8 p.m. Weekly Meeting. 9 p.m., Mr. Cecil Smith, "The Art of the Ionian Greeks."

Civil Engineers, 25, Great George-street, S.W., 8 p.m. (Students' Meeting.) Mr. P. J. Risdon, "The Reconstruction of the Santa Lucia River Bridge, Uruguay."

Astronomical, Burlington-house, 5 p.m. Annual Meeting.

Architectural Association, 18, Tufton-street, Westminster, S.W., 7½ p.m. Mr. C. S. Spooner, "Church Fittings."

Clinical, 20, Hanover-square, W., 8½ p.m.

SATURDAY, FEB. 11...Royal Institution, Albemarle-street, W., 3 p.m. Sir Alexander Mackenzie, "The Bohemian School of Music." (Lecture II.)

Journal of the Society of Arts.

No. 2,725. VOL. LIII.

FRIDAY, FEBRUARY 10, 1905.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

NOTICES.

NEXT WEEK.

MONDAY, FEBRUARY 13, 8 p.m. (Cantor Lecture.) DUGALD CLERK, M.Inst.C.E., "Internal Combustion Engines." Lecture I.

WEDNESDAY, FEBRUARY 15, 8 p.m. (Ordinary Meeting.) ARTHUR HENRY ANDERSON, "The Decline of the Country Town."

THURSDAY, FEBRUARY 16, 4.30 p.m. (Indian Section.) SIR CHARLES A. ELLIOTT, K.C.S.I., "The Indian Census of 1901."

Further details of the Society's meetings will be found at the end of this number.

CANTOR LECTURES.

On Monday evening, 6th inst., Mr. JAMES P. MAGINNIS delivered the third and last lecture of his course on "Reservoir, Stylographic, and Fountain Pens."

A vote of thanks to the lecturer was passed on the motion of the Chairman.

The lectures will be published in the *Journal* during the summer recess.

MAP OF THE NILE.

With this number of the *Journal* is issued, as a supplement, a map illustrating Sir William Preece's paper on the "Navigation of the Nile," published in the last number. (See *ante*, p. 274.)

PROCEEDINGS OF THE SOCIETY.

COLONIAL SECTION.

Tuesday, January 24, 1905; Sir EDWARD A. SASSOON, Bart., M.P., in the chair.

The paper read was—

BRITISH COMMERCIAL PROSPECTS IN THE FAR EAST.

BY BYRON BRENAN, C.M.G.,
Late H.B.M. Consul-General at Shanghai.

The subject of my paper is "British Commercial Prospects in the Far East." This covers an enormous field, and in the time at my disposal it would be impossible to do more than treat very superficially a variety of questions, with the result that at the end of my address my audience would only carry away a very confused mass of ill-assorted information. It will, therefore, be better, I think, to confine my remarks to China, which, after all, is quite large enough to occupy our attention for one afternoon, and is also a portion of the map of Asia, where I feel on firmer ground than in the neighbouring countries.

In order that you may be able to follow what I am going to say, I shall begin by explaining the conditions under which British subjects and foreigners generally may now engage in business in China. By the word "foreigners," which I shall use frequently, I mean non-Chinese subjects of all nationalities.

THE PRESENT SITUATION.

In virtue of various treaties, foreigners may reside permanently in certain towns and places. These are officially called "Treaty ports," but as some of the more recently opened places are in the interior, and remote from navigable waterways, they can scarcely be

called ports. The names of some will be quite familiar to you: Shanghai, Canton, Hankow, Tientsin, for example. Of these places, there are eleven on the sea-board, fourteen on navigable rivers, and a few inland. At all these places foreigners may establish themselves in business, and import or export merchandise on payment of a certain duty fixed by convention, and it is important to remember that Chinese subjects at these Treaty ports are put on the same footing as regards the payment of duties and the distribution of goods as the subjects of foreign powers, the principle being recognised that the tariff applies not to the merchant but to the merchandise.

On first thoughts it might seem that the more there are of these places the better; that if we could plant our merchants all over the country it would be a great advantage. But this is not so. In practice it is found that new Treaty ports do not attract the foreign merchant, and for the adequate reason that there is no money to be made by settling there. The simple explanation is that, for all business purposes at all the Treaty ports, the Chinese merchant has all the advantages of the fixed tariff charges which have been secured by the foreigner, and can carry on the business of buying and selling at less expense than his European rival. The tendency is becoming more and more for the Chinese, who are the distributors of imports from foreign countries, and the collectors of native produce intended for exportation to foreign countries, to buy and sell at one of the few great *entrepôts*, of which Shanghai is the chief.

Too much is made of the opening of new ports. Some of the more recently opened Treaty ports have never been visited by a foreign merchant. The history of their opening is usually this. Something unpleasant has happened in China, and there is a storm of indignation in England. We don't see our way to enforcing proper satisfaction, so, somewhat on the principle, I suppose, of any port in a storm, we demand the opening of one or more ports. The Chinese Government are shrewd enough to know that what is easily obtained is not much valued, so they set up one objection after another for us to demolish, and when they think we have forgotten all about the original cause of quarrel, they consent to open a port, and then port and all is forgotten. As an example, a thick Blue-book of the year 1899 concludes with two telegrams—the first from the British Minister in Peking, reporting that the port of Nanning, in the Kwangsi province, has been declared open by Imperial decree; and the second from the Secretary of State for Foreign Affairs, sending his congratulations on the result, which he considers very satisfactory. Well, nobody has been near Nanning since. In 1897 I made a report to the Foreign Office, in which I called attention to the small number of British firms then existing in China. There were eighty in Shanghai, and fifty-three more were distributed among eleven other ports. Six ports had none at all. Since then I do not think the figures have changed much, except that some half-a-dozen more ports have been opened without attracting any British merchants.

In spite of the opening of new ports, the tendency is for foreign merchants to concentrate at the principal places, and, as I have said, to leave to the native dealer the work of distributing foreign merchandise and of collecting native produce; and so I think it will continue to be, no matter how much the country may be thrown open to the foreigner, how greatly the means of transportation may be improved, or how many new markets may be discovered. Nor need this prospect be viewed with regret. As a nation we are chiefly interested in the volume of trade; the prosperity of the British merchant established in China is a matter more of individual than of national concern.

That the volume of trade is not as large as under more favourable conditions it could be is evident. Japan, with a population of one-sixth, spends almost as much as China on foreign goods. India, with a smaller population, has a foreign trade more than twice as large as China; and yet, as trader, artisan, or agriculturist, the Chinaman can give the other two a long start and beat them. What then is the explanation? It is mainly that the Chinese Government does not give a thought to such matters as the expansion of commerce, or the development of the resources of the country; and, furthermore, without considering the direct or indirect consequences of its action, it will, in the pursuit of some local, temporary, and insignificant gain, blindly adopt measures which end in strangling trade and killing enterprise. Such progress as we may notice has been made in spite of, and not in consequence of, Chinese official action. Our own statesmen do not seem able to agree as to what is the best fiscal policy to adopt, but there is one point on which there would be no

difference of opinion, and that is that China's fiscal policy is wantonly suicidal.

Of the fiscal errors committed by China's rulers I could give you a long string of examples. One will enable you to judge of their manner of looking at things. When a new Commercial Treaty between China and this country was being negotiated a couple of years ago, we on our side claimed that any import duty put upon British manufactures should be balanced by an equal duty or excise on Chinese manufactures of a similar nature. From another quarter came a suggestion that some preference should be shown to native industries. This was strenuously opposed by Chang Chih Tung, one of the Chinese negotiators, and one of China's foremost and most influential officials. Far from desiring to give encouragement to the Chinese production of foreign things, he was disposed to render Chinese competition impossible, and why? Because if China could manufacture any foreign article for herself she would cease to import it, and then China would lose the import duty. This narrow view, that the chief function of trade is to bring in revenue to the Imperial exchequer, seems to possess Chinese officials and their foreign advisers alike. Any facility given to commerce is looked on as a dangerous innovation, as a generous concession, and as a relaxation of some necessary restriction which must be well paid for.

When that good time comes that China, in proportion to her population, has as large a foreign trade as Japan, here are a few of the improvements we may see. Of cotton tissues, China will import nearly three times as much as she does now; of woollen goods, nineteen times as much; of iron, steel, and other metals, six times as much; of machinery, twenty-six times as much; of electrical materials and fittings, three times as much; and so on for many other articles.

Our chief hope in the future must rest not on our Government obtaining for British subjects more facilities or so-called privileges than they already enjoy under existing treaties, but rather in utilising every opportunity that presents itself for inducing the Chinese Government to give its own subjects a fair chance by granting them full liberty to improve their position and grow rich. The people of China within their limits are free spenders of money; what in our own interest we should wish to see is that they should have more money to spend. British commercial prospects in China are intimately connected with the development of China's material resources, and whatever we can do towards removing the difficulties that beset the industrious classes in that country will be a service which will be repaid to us with interest.

RAILWAYS.

It is in the construction of railways and in the opening of mines that the profitable employment of capital might be looked for, and I propose to give my idea of what are our prospects in this direction.

When the map of China is looked at, the thought at once arises that millions upon millions of British money might be profitably invested in the construction and equipment of railways alone, but as one comes to closer quarters with the question one realises that the prospect is not so alluring. The building of railways has but recently begun, and, to judge from the start that has been made, it looks as if it was the desire of the Chinese Government that the railways of the country should be a State enterprise.

Speaking in a loose sort of way, certain foreign syndicates are said to have obtained railway concessions. This is somewhat misleading. With the exceptions I shall mention presently, all the agreements for the construction of railways which have been signed so far are drawn up on much the same plan. When the Chinese Government has decided that a certain line may be constructed, a foreign syndicate makes an estimate of the cost, and the Government authorises the syndicate to place a Chinese Loan on the foreign market for the necessary amount. The usual terms are that the Chinese Government shall receive £90 net for each £100 bond; the rate of interest is 5 per cent., and the security is the earnings of the railway, and, in default of these, the revenues of the Empire. As a guarantee that the money shall really be spent in building the line, the construction is entrusted to the syndicate interested, and the control of the accounts is also largely left to it, and after the line has been completed, the syndicate, as trustee for the bondholders, is given a preponderant voice in the upkeep and running of the railway. The Chinese Government reserves the right to redeem the bonds in a certain number of years, and when the loan has been completely paid off, the railway is to become the absolute property of the Chinese Government. The holder of a Railway Loan Bond is thus in the position of a preference shareholder, and all that the syndicate gets

out of the business is such profit as it can make in floating the loan, a commission on the purchase of materials, and a share amounting to one-fifth of the net earnings of the line after the interest on the loan has been paid.

Having begun in this way, it is probable that these are the best terms which the Chinese Government will be willing to give when any more railways are applied for by foreigners. Indeed, it is to be feared that an attempt will be made to reserve to the Chinese a greater share of the control, and that to this extent the security of the bondholders will be impaired. With the experience they have gained in the railways already under construction, the Chinese have come to think that their authority and their interests are too little considered, and in future cases they may seek to remove the defects which they see in the earlier contracts. The credit of the Chinese Government is not so good that the British bondholder can afford to look to that except as a forlorn hope. If he is a wise man, it is to the railway and its earnings that he must look for the payment of his interest and the eventual return of his capital. No matter what the earning powers of a railway might be, it is absolutely certain that under purely Chinese management the upkeep of the line would be neglected, and the earnings would be swallowed up by a numerous staff composed of the friends and relations of the Board of directors. It is absolutely essential that those with whose money a railway is built must be in a position to prevent waste and mismanagement. Unless this can be guaranteed, foreign capital will not be obtained from those quarters where railway construction is looked upon honestly and simply as a financial investment. There may, of course, be cases where the security of the 5 per cent. interest is a minor consideration, and where, for political reasons, means may be found of providing the requisite amount on China's own terms. It is here that the British capitalist is at a disadvantage. Without pretending to be behind the scenes as to the ways of other Governments, I am convinced that our Foreign Office will never consent to infuse confidence in the British capitalist by hinting that they will see that he comes out all right in the end if he will but secure some sort of a contract now.

At present the interest on the bonds is coming out of capital, so it is too soon to know how these contracts will work out in the long run. Once a line is completed, however, such interest has to come out of the earnings. It is quite possible that before long the Chinese Government will be called upon to make good a deficiency in this respect, and it will then take alarm, and be shy about guaranteeing any more loans. Indeed, already the Chinese are representing that it is unjust for foreigners to press them to borrow money for the construction of railways which the foreigners themselves do not feel confident will earn 5 per cent. If the importunate foreigner is sure the line will pay 5 per cent., they say, why insist upon a Government guarantee? And if he is not sure about it, why put pressure on China to authorise the construction? An awkward question to answer, certainly, and the best answer we have discovered so far is that, as others are doing this, so must we.

It is a mistake to suppose that the rulers of China are persuaded that they must have railways, and that as China cannot finance them they must have recourse to the foreigner, and make the best terms they can with him. Many enlightened Chinese do see the advantage of railways, but it is not with these that the decision rests. Those who have the final say in the matter care little whether railways are built or not. They have but a dim idea what prosperity attends improved means of communication; moreover, a desire for the welfare of their country is only felt in an abstract sort of way as a good theme for an examination essay, but it does not form part with them of what is called practical politics. What they do realise is that foreign railway concessions are liable to involve them in worries and land them in difficulties, and that on the whole it is best to leave well alone.

The English capitalist will go the wrong way to work if he begins his negotiations in the spirit of the man who holds the purse strings and can command his own terms, and who thinks it an unanswerable argument that unless certain conditions are granted it will be impossible to float a loan. This may, indeed, be the case, and may be very convincing to the would-be contractor, but it does not convince the Chinese negotiator, who, be it remembered, is not particularly anxious to be convinced.

Now I come on ground where I must proceed warily. It is not only British financiers and concession-seekers who wish to place their services at the disposal of the Chinese Government. There are others, and the Chinese, both in politics and in business, have ever been expert at setting one nationality against another. It is pretty certain that

every draft contract and every estimate which is submitted to the Chinese is picked to pieces and misrepresented by jealous competitors and by political opponents. The jealous competitor will offer to do the same thing on better terms, and the political opponent will fill the suspicious Chinese officials with nervous apprehension; for to spoil another's concession is almost as sweet as securing one for oneself. As we say in private conversation, I will not mention names, but I have known the representative of one foreign Government, who had a railway under his protection, threaten to demand heavy damages from the Chinese if they permitted the construction of a certain line which another syndicate was trying to obtain, his disingenuous pretext being that it might become a competitor, and this proved sufficient to spoil the business.

When one party is trying to secure the financing and construction of a line, and offers terms which are in every way fair and reasonable, it makes his position very difficult if another person, especially of a different nationality, is underbidding him, or, at any rate, offering terms which may on the surface seem to be less onerous; and I need hardly say that when an agreement is being discussed for the construction of a railway, the only specification being that it shall extend from this town to that, it by no means follows that the lowest estimate will turn out to be the cheapest. To a large extent the Chinese have to take your word for it what things cost, and how much is expended on construction as the work proceeds; so, with the spending of the money and the preparation of the accounts left entirely to him, you can conceive how a man who is well equipped with mental reservations may be willing to undertake the task on very low terms, and to find the money as low even as 4 per cent.; and here I must leave you to draw your own inferences.

It is an open question when constructing a railway tentatively in a new country whether it is the better plan to make a first-rate job of it from the beginning, regardless of cost, so that no expenditure on repairs or improvements will be required for years, or whether to build as cheaply as possible by beginning with a single line, using light rails, and erecting wooden bridges and temporary stations, and thus put off the heavy expenditure necessary to convert it into a first-class line until this can be done out of the earnings of the line itself, or until the fact that the line is earning profits makes it possible to raise money on cheaper terms. Whichever may be the soundest policy from the financial point of view, I am inclined to think that the person who proposes the cheap and gradual method has the best chance of getting the business from the Chinese. They have no experience of railway finance, and it is Chinese nature to prefer paying twice by-and-bye to paying once on the spot. To them the ideal railway would be the one that could grow out of its first ten miles, like a plant grows out of a small seed. Another consideration which will carry weight is this: that the constructor who spends a large part, and even an unprofitable part, of the available money in the purchase of Chinese materials, and, as it were, does not take the money out of the country, will be going a long way towards ingratiating himself with his Chinese employers. In pursuance of this policy, the Belgians, with an eye to future favours, are buying largely from the Government iron-works at Han-Yang for the line they are now constructing.

It is now time that I should tell what are the railways for which agreements exist on the terms I have indicated above. They are:

1. From Peking to Tientsin and Newchwang, with a branch from Kou-pan-tzu to Sin-min-tun.

This has been in operation for some years. It has been built partly with Chinese and partly with English money. Our control is consequently not quite so extensive as in the other railways, but sufficient to safeguard the interests of the British bondholders.

2. From Peking to Hankow. This is a Franco-Belgian undertaking, and it is completed all but a long bridge which will span the Yellow River.

3. From Kai-feng-fu to Ho-nan-fu. This is also a Franco-Belgian line. No work has yet been done.

4. From Cheng-ting-fu to Tai-yuan-fu. This is a Russian undertaking, and a beginning has been made.

5. Hankow to Canton. A certain amount of work has been done at the Canton end, where a branch line has been built as far as Samshui, but now there is a hitch. The Americans do not seem able to find the money, and they have transferred a large share of their interest to the Belgians. On this ground the Chinese are trying to cancel the agreement.

6. Shanghai to Nanking. This is a British enterprise, and the work was recently begun.

There are other railways for which preliminary agreements on the same basis exist, but the final agreements have yet to be negotiated,

and it is probable that no further steps will be taken until it is seen how the lines now under construction pay. These railways in embryo are:

1. From Soochow to Hangchow and Ningpo.

2. From Pukow, opposite Nanking, to Sin-Yang, where it will join the Peking-Hankow railway.

3. From Kowloon, opposite Hong-Kong, to Canton.

All these three are British undertakings.

4. From Tientsin to the Yangtze river, either at Chinkiang or Nanking. This is an Anglo-German interest.

In addition to the above there are other railways in the Chinese Empire, either completed or in course of construction, which are not Chinese State railways. These are:

1. The Manchurian Railways, from Port Arthur to Harbin. These have been built entirely with Russian money, and controlled by Russia. Their future status will probably be decided when terms of peace are arranged between Russia and Japan.

2. The Shantung Railways, from the German port of Tsingtao (Kiaochow) to Tsinan-fu, the capital of the province. This has been built with German money, and is German property.

3. From Ching-hua to Tao-kow, in the province of Honan. This is completed, and has been constructed by the Peking Syndicate (a British concern) with its own money, but there is a probability of its being taken over by the Chinese Government on the 5 per cent. loan plan.

4. From Macao to Samshui. A concession has been granted to a Portuguese-Chinese company.

5. From Langson, in Tongking, to Nanning, on the West River.

A French company has a concession for this, but no work has yet begun.

6. From Laokai to Yun-nan-fu, the capital of the province of Yunnan.

A concession for this has been granted to a French company under French Government control.

So far then, the English are only engaged in the construction of one railway—from Shanghai to Nanking. On the successful issue of this undertaking a great deal depends, for the Chinese will soon have the opportunity of judging which of the several foreign companies is serving them best. So far, everything is in our favour. To begin with, the Shanghai-Nanking Railway passes through the richest portion of China, and if railways are to be remunerative in any province, this railway has the best chance.

Then we ought to profit by the mistakes of others. I do not mean mistakes in construction or management, but mistakes in our attitude towards the people or the officials. What they do not like is a disposition to brush them aside when they seem to take an interest in the business, and they silently resent being ignored as the proprietors of the railway. What will tell in the long run is the reputation for good faith and fair dealing, or the reverse, which the different syndicates now engaged in railway construction establish for themselves. In the eagerness to secure immediate profits this fact is apt to be lost sight of. A shabby trick or a bit of sharp practice which may bring in an immediate thousand pounds will cost more than a hundred thousand in the hereafter.

The question whether the extension of railways will proceed on the plan on which they began—I mean the Government loan system—will depend on the financial success or the failure of the lines now building. If they prove a success, the 5 per cent. interest and contingent profits will probably appeal to investors in foreign countries, and, on its side, the Chinese Government will favour a method which brings them in a revenue and involves them in no responsibility. Should, however, the railways fail to pay their way, and the Government is called upon to make up a deficit, it will probably leave the extension of railways to those who are willing to take the risk.

Except in a few favoured localities, I do not think that at present foreign capitalists are prepared to construct railways on their own account, and merely rely on the earnings of the line for their reward, and I do not believe that the Chinese Government would view favourably any such schemes. It must not be forgotten that, in China neither foreign subjects nor their property are subject to Chinese law. This is the chief reason why foreigners and their operations are restricted to the open ports, where courts exist administering their own laws before which they can be called to account. Questions of all sorts in connection with a foreign-owned railway would arise in the interior, and there would be no means of obtaining redress. To conceive what confusion and complications would ensue, one must imagine the Midland Railway owned and managed by Frenchmen, and every time there

was a claim against the French company or its servants, the plaintiff was told he must go to Paris to seek redress; or, still worse, that no legislative enactment of our Board of Trade affecting the railway could be put in force without the consent of the French Government.

The Chinese Government has not the same reasons for objecting to railways being constructed by Chinese with Chinese capital, and there has been a good deal of talk of forming Chinese joint-stock companies; but I much question whether the money exists, or whether Chinese shareholders would have sufficient confidence in their directors, or could trust their officials to keep their hands off the earnings. Such a railway would be expected to render gratuitous service to the State, and when it comes to this sort of thing, there is a wonderful amount of travelling on Government account.

A danger to which capital invested in private railways will be exposed must not be overlooked. China is a country where rebellions are frequent, and it is the habit of insurgents while they have the upper hand to make a clean sweep of everything. In certain places within easy reach of assistance, foreign powers might take steps to protect a railway built with their people's money, but most parts of China are inaccessible to foreign ships or troops. If destruction on a large scale took place it would be difficult to obtain compensation. The national revenue of China is already deeply pledged for the payment of loans and indemnities due to foreign Powers, and it is doubtful whether more could be wrung out of the Government without having recourse to force. It is true that during the Boxer trouble the railways in the north were partially destroyed, and compensation was exacted, but the Chinese Government was held to be responsible for the damage, and, moreover, the occupation of the capital and the presence of a large number of foreign troops left the Chinese no alternative but to submit.

I must refrain as much as possible from touching upon politics, but closely connected with our future trade is the tendency of some Powers to mark off certain parts of China as their especial sphere of interest or influence. It may be permitted to hope that, as one outcome of the war now proceeding in the Far East, all tampering with the integrity of China will cease, and that some sort of Monroe doctrine will be proclaimed. The Chinese Government, left to itself, is willing to give to every country, I will not say a fair field and no favour, but, at any rate, some sort of a field and no favour; but a sphere of interest has a way of developing into a sphere of influence, and then into an exclusive preserve. The manner in which railways are being financed opens the way even now to preferential treatment. It is not much good having an impartial tariff of duties for all sorts of merchandise if the railway directors are able to counteract this by fixing arbitrary rates of freight, and it is not at all impossible that those who have the control of a railway could make it very unpleasant for any British enterprise which depended for its success on punctuality in transportation and on reasonable rates of freight. The fact that the control of railways will be left very much to companies of different nationalities, and in some cases to companies that must do the bidding of their protecting Governments, must cause some anxiety, and supplies a strong reason why it is desirable that the whole railway system of China should pass under one honest, impartial, and competent management, if such can be devised.

In order to make my meaning perfectly clear, I will imagine two possible cases. Two companies, one English and one French, have petroleum wells in the province of Ssuchuan, and the only exit is over a railway controlled by the same French company. Is it not easy to see what the result would be? Or take another case. A rich district is at the terminus of a railway under German management. At a certain town there is a junction with a British railway by which the coast can be more easily reached than by continuing the journey on the German railway. Would there not be a temptation to so arrange the through rates as to deprive the English railway of its legitimate share of business?

MINES.

It is in the exploitation of her mineral resources that one might look for a great improvement in China's material condition. We know what the potential wealth is in this direction, and one impatiently longs to bring this wealth to the surface. With coalfields, it is said, sufficient to supply the whole world for 3,000 years, China is annually importing coal to the extent of 1,400,000 tons at a cost of one million sterling. Practically, mining has not yet begun; a little scratching here and there, but except in one instance nothing is being done on a large scale. I think it is here rather than in railway extension that there are attrac-

tions for the employment of British capital, and what is of as great importance as the profitable employment of British capital is the improved condition of the people which must result from the opening of a new industry on a large scale. Left to itself, the Chinese Government is willing to leave all minerals where they are now—safe beneath the surface; but once the persistent foreigner insists on being given an opportunity of extracting them, Chinese subjects will follow in his wake, and claim their share of the newly-discovered riches. Here, as in many other instances, we shall probably fight the fight, and the Chinese will reap the fruits of victory, but it all makes for what should be our chief aim: the amelioration of the condition of the Chinese people.

In the new Commercial Treaty, which owes its existence to the Boxer outrage, China undertook within one year to conclude the revision of the existing mining regulations. She promised that

"With all expedition and earnestness she would go into the whole question, and, selecting from the rules of Great Britain, India, and other countries regulations which seem applicable to the condition of China, she would recast her present mining rules in such a way that, while promoting the interests of Chinese subjects, and not injuring in any way the sovereign rights of China, these rules should offer no impediment to the attraction of foreign capital, or place foreign capitalists at a greater disadvantage than they would be under generally-accepted foreign regulations."

This is the sort of fine-sounding obligation that the Chinese Government like to enter into, for they think that the chief value of a Treaty article is its elegant phraseology, and they have come to believe that we set as great store by the shadow as by the substance. It is now over two years since the Treaty was signed, but the new mining regulations framed in the spirit above indicated have not yet appeared. One or two sets of mining regulations, it is true, have been published, but they appear to have been framed with the object of discouraging the employment of foreign capital in the industry. They provide that in any joint-stock company the majority of shares must be Chinese owned; Chinese mine-owners may not borrow money from foreigners on the security of the mine, but only on the machinery and buildings, and this only after the permission of the official Mining Board has been obtained. The mining licences are to be for only thirty years, and may only be granted in respect of an area of ten square miles. Pit-mouth royalty on coal, antimony, iron, alum, and borax, is fixed at the rate of 5 per cent. *ad valorem*; on petroleum, copper, tin, lead, sulphur, and cinnabar, at the rate of 7 per cent.; on gold, silver, platinum, quicksilver, and spelter, at the rate of 15 per cent.; and on diamonds and precious stones at the rate of 20 per cent.

It now remains to be seen what modifications will be introduced in order to bring these rules into harmony with the spirit of the Treaty, but, meanwhile, with unknown regulations hanging over their heads, British companies or individuals are not disposed to go to the expense of making preliminary researches.

Chinese provincial authorities, for a consideration, have a way of granting exclusive mining rights to large slices of their provinces, and the concessionaires put these away in their desks until it suits them to begin operations. Thus, in the latest report of the British Commercial Attaché in China, it is stated that the provincial Government has granted exclusive mining rights in the north-east of the province of Fukien to certain Chinese and French concessionaires, and a French mining engineer of high repute has obtained a careful survey of the goldfields in that locality. These are described as very valuable, and a company is being formed to commence operations. As a precaution, it would be well to make the Chinese Government redeem their promise as regards liberal mining regulations, and meanwhile urge them to withhold all concessions until the promised regulations have been published. Otherwise we shall find all the best places have been reserved wholesale.

Internal Taxation.

If I were asked what measures would have the greatest effect on the material prosperity of China, I would say, first, the total abolition of every form of internal taxation on merchandise, and, secondly, improved means of communication. Our Treaties merely concern themselves with imports and exports, and theoretically the extent to which these may be taxed is fixed; in practice, as forty years of experience have taught us, the safeguards provided by the Treaties are effective only so long as the foreign merchant has a personal interest in the property, and keeps his eye on it. Particularly in the case of exports is the limitation fixed by treaty a delusion. Goods which may perhaps be exported eventually form part of the domestic trade of the country in the earlier stages of their existence, and during this

period they are liable to be burdened with every legal and illegal tax which ingenious and rapacious tax collectors can invent. It is only after they have been sold to a foreigner, and have been ear-marked for exportation, that the protective clauses of the Treaties come into operation. We know how the commerce between two independent countries can be injured and even killed by excessive and uncertain duties. In China it is not a question of independent countries, but of adjacent provinces, even of neighbòuring districts, one might almost say, of next-door villages. In America, I suppose a man could start with a carload of Californian canned goods, and take them through every State of the Union, and finally find a market in New York, without having been questioned or delayed, or taxed by any Government official. In China, on such a journey he would have paid out much more than the goods were worth, or he would have had to sell the best part of his cans to pay the taxes on the survivors. Under such conditions, what chance is there for any district to do itself justice by producing the very things it is most suited for, and disposing of them in the best markets? It is not only the crushing burden of taxes that the producer has to reckon with, but there are the delays, worries, and persecutions which the owner of the goods is exposed to when he ventures on a journey. In America, a man in Florida can calculate at what price and in what time he can deliver fruit in Chicago, and he makes contracts accordingly. The southern man in China can make no such calculations. His wares on arrival at destination might cost 20 per cent. more or 20 per cent less than he calculated. Production to the utmost capacity in any locality is thus much discouraged, and districts within certain limits have in a great measure to be self-supporting. The channels through which districts remote from each other can most easily exchange their products are those that exist by means of steamers plying between Treaty ports, and this relief to domestic trade is an indirect and uncalculated result of foreign Treaties with China.

It is not only the practices of the native tax officers in the interior which call for criticism and are capable of improvement. The remedy here, I fear, must wait until wiser counsels prevail at Peking, or until some events, unforeseen at present, place the foreign Powers who wish China well in a position to compel reform. The opportunity of a lifetime came in 1900 when after the Boxer affair foreign troops occupied Peking, and the terrified Government was in the mood to make adequate reparation. Here was the opportunity to render the people of China great service by exacting from them what a wise and good Government ought to give to its people voluntarily. The foreign Powers, acting in concert, need have asked for nothing which would not in the first instance have been of direct advantage to the country, and our compensation would have come later in the shape of a vastly increased trade. But unfortunately the foreign Powers interested seemed unable to act in concert, except for the rather ignoble purpose of extorting money out of the Chinese Government, which, of course, meant money extorted from the Chinese people. Everything else but indemnity seems to have been lost sight of, and day after day for some six months the representatives of foreign Powers were engaged in discussiug the ways and means of China to make up a sum of £65,000,000, and when this had been satisfactorily arranged, more discussions took place as to how the spoils should be divided. After this came the turn of the Chinese Government to apportion the debt over the various provinces, and then the innings of the tax gatherers, who proceeded to collect from the merchants and people twice as much as was required. This opportunity has gone, and if it requires the same series of atrocities to bring it back may it never return.

But there are certain obstacles in the way of trade which, as they are caused by the unreasonable application of regulations framed for other purposes, and are the direct outcome of our negotiations with China, might be removed on the representation of foreign Powers. The rules which were framed over forty years ago when the Treaty ports were few are made to do duty now when the conditions are very different. In some instances the result is absurd, but as it does not affect the resident merchant directly, the injury to trade in general is overlooked. In order to justify my criticism, I must give you one or two examples, and this necessitates a little preliminary explanation. Imports from foreign countries and exports to foreign countries pay a duty of roughly 5 per cent. This is collected by what is known as the Maritime Customs—a well-administered service organised by Sir Robert Hart. In the early days, what is known as coast trade—the French *cabotage*—really was a coast trade, that is, it meant the carriage of merchandise by foreign sea-going

vessels from one coast port to another. The duty on such merchandise is 5 per cent. at the port of shipment and 2½ per cent. at the port of discharge, 7½ per cent. in all; so here is the anomaly of the Chinese paying a higher rate of duty on what is produced in his own country than on a similar article imported from abroad. As a matter of fact, the home-made article is much more severely handicapped than this, but it would puzzle you if I attempted to explain the complicated fiscal absurdities which bring this about. You must take my word for it that it is so, and one ludicrous result is that in some cases Chinese produce is sent from one part of China to another, not by the most direct route, but in a roundabout way through a foreign country, as thereby it becomes classed as a foreign import; and such preference is there accorded to foreign imports as distinguished from native goods that it is profitable to pay two duties—one on exportation and the other on reimportation—merely for the sake of giving the article a pseudo-foreign character.

Can you conceive English-made goods from Liverpool being cleared for Antwerp and then re-imported into London, and paying duties both ways, because by so doing it escaped heavier duties? Well, this is what happens in China. The neighbouring British colony of Hong-kong, a foreign port *qua* China, seems to have been sent by providence to facilitate this operation.

This rule which requires Chinese goods from one coast port to another to pay a duty of 7½ per cent. has been extended to all places, even in the interior, which are open to foreign merchants, so we now witness the absurdity of native produce paying this duty when carried by ships between two places only a few miles apart. But still worse fiscal enormities are perpetrated in China. The disabilities under which native manufactures labour may be estimated if I give a typical case—that of matches. All the component parts, wood, chemicals, and everthing else, pay import duty at Shanghai. Then the finished article pays export duty on leaving Shanghai, and another import duty on arrival at Canton; that is, it would pay all this if it could stand it, but it has given up the attempt long ago, and now Chinese use Japanese matches. I will only cite one more instance. The north of China produces a certain kind of wild silk. There would be a sale for it in Europe if it was wound in hanks of the proper size, but this can only be done by expert hands in the Canton province. I believe one venture was attempted, but it could not be followed up because, on leaving the north the silk had to pay one duty, on arrival at Canton it had to pay another, and then a third duty when it was exported from Canton. This all comes from the bigoted idea that trade exists only to be taxed, that merchandise must pay for the privilege of moving about, and that if it cannot afford to do it it had better stay at home. This is not exactly killing the goose that lays the golden eggs, but it prevents the hatching of the egg that would produce that goose. All of which reacts very injuriously on our own trade with China.

Steam Navigation in Inland Waters.

Much was expected from the opening of inland waters to steam navigation, but again unreasonable restrictions and vexatious regulations have marred what might have been a concession of real value. Under the existing rules, one class of steamer may ply between two Treaty ports, but may not carry goods for intermediate places. Another class of steamer may carry goods to intermediate places, but may not go as far as the next Treaty ports; it must return to the port whence it started. Our English rivers are too small to enable me to give you an example, but a railway will serve the purpose. It is as if the Board of Trade were to make regulations allowing the London and South-Western Company to run goods trains from London direct to Portsmouth, but forbidding these trains to deliver goods at Guildford or Haslemere. Goods for these latter places must be sent by another train, which, having accomplished its mission, must return to London.

China is blest with a good system of waterways, and where these are available Chinese people know how to take full advantage of their opportunities, but waterways after all are but thin threads on a map, and the greater part of the country has to depend on other means of communication. Roads in China, as we understand roads, do not exist; there is a right of way and that is all. When land transport has to be resorted to, the distance which it is profitable to move goods is very limited. Cart hire comes to nearly 3d. a ton a mile; pack animals about the same; and porters' wages would work out at about 4d., but the excessive cost is not all; goods that can only be moved ten to twenty miles a day it often does not pay to move at all. Facilities for rapid and cheap transportation create a trade

where no trade existed before, as the few railways now in operation in China have amply shown; and new industries crop up as soon as means are provided for conveying the product to a market. If ever the time comes in China when her products can be moved all over the empire without let or hindrance at the rate of a penny a ton a mile, there will be no repining for the good old days. And it will be then that her commerce with other countries reaches a volume commensurate with her natural resources and the industry of her people.

It is now time that I returned to my text, and took upon myself the risky task of forecasting the future.

Future Developments.

As it has been slowly doing in the past, China's international trade, in the absence of greatly disturbing causes, will continue to grow in the future. Even without any systematic effort on either side, continuous intercourse between buyers and sellers must occasionally suggest some fresh opportunity of doing business; such an industrious people as the Chinese if left undisturbed, does not consume its capital, but continues to accumulate it; and even under the existing *régime* a gradual improvement is discernible. At the present time, we English are satisfied that we have a fair share of the China business; by-and-bye when this business has increased considerably, and our own share has also grown, we shall yet be disappointed if we find that in comparison with other nations we have not been progressing in the same proportion; but it will require more energy than we are now displaying, and also a change of tactics if we are to improve, I do not say only to the same extent, but in the same ratio as others.

If the British manufacturer is desirous of seeing a greater demand for his goods, I do not think he must look for assistance from the British merchant in China. The resident merchant in China can be trusted to look after his own interests; but he does not consider it his business to develop the commerce between East and West except when he sees a personal gain in doing so. The larger firms who have capital have tried various methods and have settled down to a beaten track which answers their purpose. They will be pleased to do a larger business with any one who comes to them; but they do not attempt to find new markets for their goods or other people's, nor to discover any new products suitable for shipment to Europe. They are satisfied that all that their own efforts can accomplish with profit has been done, and they are content to wait until more business comes their way. Indeed I imagine that some of the prosperous firms would ask "Why don't you leave well alone?" for I can easily conceive how, under changed conditions, our trade with China might largely increase without proving profitable to those already in the field. Changed conditions might bring competitors who under present conditions would have no chance.

Under the present order of things manufacturers at home can scarcely regard the merchant in China as adequately representing their interests; and although they can only act effectively in China through Englishmen resident there it would seem that they should themselves watch the course of events in that country very carefully for themselves.

British trade in China, that is to say trade conducted not only in British goods but by British hands, has undergone a transformation. The change has been gradual and has extended over many years, and those engaged in it have found it difficult to adapt themselves to the new methods. The metamorphosis is not so much in the British trader himself as in those with whom the trade is conducted, viz., the Chinese. British trade still flourishes, but its profits are no longer distributed in the same direction, nor do they benefit the same persons. The Chinese purchaser has been learning how to dispense with the British intermediary, and the smaller British merchant of the old school finds his old occupation gone. There was a time when the British merchant had few rivals in the field. Now he has many, and his European competitors are yearly becoming more numerous and formidable. They come unhampered with old associations and prepared to adapt themselves to the new conditions. Hankow is a notable example of this. For them the dwindling tea trade is a matter of no concern; they never depended on it, and they have been content to look out for something new. The silk trade also is not such a British preserve as it once was; it gives a living to merchants of other nationalities. Thus British firms grow less in number, and our European rivals fill the gap. When a new opening presents itself the aforesaid rival is quicker to seize the opportunity. Hankow is losing its tea trade with Europe, but new exports have been found to take its place. The new trade, however, is chiefly in the hands of French and German firms. Again, the Germans and the

Belgians have secured for themselves all the Chinese contracts for machinery of every description, the local arsenal, ironworks, and mint being fitted with their manufactures. The blame here, as in other branches of trade, would seem to lie with the firms in England who make no serious effort to push their goods in opposition to those of other countries. To send illustrated catalogues and price lists to local firms is not enough. The only effectual method is to send accredited agents with full particulars to the official in charge of factories in order to expound the advantages of British-made machinery, or to native merchants in order to point out the superiority of the article which they are trying to sell, and to secure orders therefor. It is the manufacturer who must go to the trouble and expense of pushing his goods and creating a demand for them. When that stage has been reached he can safely leave the rest to the resident merchant. It may be too much to ask any one manufacturer to go to the expense single-handed, but it would seem possible for a number of firms who do not compete to combine in investigating the possibilities of the China market, and share the expense of introducing their goods. For, example, the demand for mechanical appliances will grow, but it will grow more quickly if the Chinaman is not left to discover the advantage of them unaided. You must have an expert who can demonstrate that an article is needed, and then proceed to inform his customers how it can be procured.

Similar enterprise as regards their own products is not, I fear, to be looked for on the part of the Chinese people. They will neither seek new markets for their goods nor try to discover new articles suitable for export. On that side of the account, therefore, expansion will be slow, the more so that one cannot look for much assistance in this direction from the local foreign merchants. For, as in the case of imports, so also in the matter of exports have the conditions of trade changed. Where, some years ago, a few large English firms with ample capital bought China's products and sent them to Europe on their own account, there are now many small firms who receive orders from Europe or America by telegraph, and who fulfil these for a small commission at no risk to themselves. The telegraph and banking facilities have made it unnecessary to possess capital, and the business of the export merchant in China has in a great measure changed into that of commission agent. One of the consequences of this is that the commission agent who is buying on a limit, and who receives his commission on the amount of the invoice, buys on the best terms he can at the Treaty port, but feels no inducement to spend his time or his money in trying to discover new articles suitable for export. This class of men, if they had inducements to go up country in the course of their own special business, could also have served the interests of the English manufacturer, but, as things are now, they can be of little assistance.

Province of Ssuchuan.

I have already spoken of the need of better means of communication. Nowhere would this bring about a greater change than in the province of Ssuchuan. The man who likes to give free play to his imagination may see a promised land in that far western province. Here is the richest portion of China, with a large population, practically living in a state of isolation. The Red Basin, which embraces about two-thirds in extent and nine-tenths in population and wealth of the province, may be taken to have an area of about 100,000 square miles and a population of 45 millions. This basin is shut in on all sides by high mountains; clouds cover it through the entire winter, keeping in heat like a glass roof, so that the climate is remarkably mild. The result is that two and sometimes three crops are obtained in the year. Gold, copper, lead, iron, coal and many other minerals are all found in the province, and sanguine people say that it will some day supply the whole of China with petroleum. This great Ssuchuan basin has excellent water communication throughout its extent, but there is only one navigable outlet, the river Yangtze. Its trade with the districts on the north, west, and south, follows mountain roads that climb the sides of the basin. These roads are difficult and dangerous, only to be passed by caravans of pack animals, and by porters. No wheeled vehicle can reach Ssuchuan from the east, and no boat either except by the Yangtze. Steamers can safely navigate the mighty Yangtze from the sea to the town of Ichang, a distance of 1,000 miles. At Ichang, goods are transhipped into native boats which fight their way for 400 miles against the current, and through the rapids and cataracts, all the way to Chungking, the commercial metropolis of Ssuchuan. This means a journey of from 30 to 45 days, and the cost of transport comes to £4 or £5 a ton.

These boats on the upward journey are hauled up by main force of trackers, as many as 300 to one junk in the difficult places. Accidents are frequent, but thanks to the way in which these boats are built in watertight compartments, the accident seldom results in total loss. Sooner or later most of the cargo arrives at its destination in some sort of condition. In the face of such difficulties this most populous and rich province is not able to exchange commodities to any extent with the outer world. But it is not only the difficulties of transportation that restrict the movement of merchandise in and out of Ssuchuan. The Chungking merchant who wishes to visit Shanghai on business must count on being absent some three months; and the inaccessibility of the province causes banking arrangements to be very defective. Two of the most serious drawbacks to merchants in Ssuchuan are want of sufficient capital, and consequent inability to make the most of their opportunities, and the length of time elapsing between the payment of goods in Shanghai and their arrival in Chungking.

I think it has now been demonstrated that steam navigation above Ichang is so uncertain and risky, that commercially it cannot pay. Given plenty of horse-power and time for effecting repairs, a steamer may as a feat be got through; but as a business venture the idea has been given up. It is railways that are wanted to put Ssuchuan in touch with the lower provinces and the outer world, and when they have been constructed, then will the visions of my imaginative friend be realised.

The War and After.

The present war cannot but have very important consequences for the commercial situation in China. It is unquestionable that for us the best thing is a strong and independent China, so we may well be pleased at the success of Japan if it puts a stop to the insidious designs of certain Powers on the independence of that country. England is very unwilling to contemplate such a thing as partition; a broken up China would be extremely injurious to our trade, and as a last resource in self-defence we would have to join in the scramble; so we earnestly try to believe that the catastrophe is not coming, and when any ominous signs appear we look the other way. What has of recent years been going on in Manchuria, in Shantung, and in Kwangsi and Yunnan might, when the occasion suited, well lead to partition. But it is to our interest that China should not only be left intact, but that she should be able to take care of herself, for when it comes to hectoring and intimidation we are not willing to go the length of others, and our friends get the advantage of us.

There is now some prospect that Manchuria will again become a field for the enterprise of all comers; only a year ago it bid fair to become a Russian preserve. The resources of Manchuria are capable of enormous development. It has at present a sparse population, and it has been estimated that not more than one-fifth of the whole arable land is at present under cultivation. Both in agricultural products, as well as in animal and mineral products, a very large trade is possible as soon as good means of communication exist. A recent traveller makes the following observation:—

"I have travelled in different parts of China, but I never saw a sight which, from its magnitude, impressed me so much with the vast trade of China as the carrying trade from north to south in Manchuria. In one day we met at least one thousand carts, each drawn by five animals, heavily laden with the produce of the interior, beans, hemp, millet, skins, &c. In one place, where a difficult gulley had to be crossed, there was at least one mile of carts, three deep, waiting their turn to pass."

I quote this passage because it will give you some idea of what Manchuria may become when goods can be conveyed cheaply and expeditiously, instead of by slow moving carts at the rate of twenty miles a day, and a cost of five shillings a ton per day.

Taking a hopeful view of the result of the war I think we shall see Japan wielding great influence at Peking. Her prestige will be enormously enhanced, and China who all along turns a deaf ear to the advice of the Western Powers, whose motives she distrusts, will lend a ready ear to the counsels of Japan. She will be willing to accept a lesson from a nation who by its own efforts in the course of one generation has risen from what in China's eyes was an unimportant State to what in China's estimation is now the dominant power in the Far East. "What Japan has done we may yet do" will be the thought passing through the Chinese mind, and the conviction will gain force that the surest way to achieve a like success is to accept her as a guide. Whether Japan's teaching will make to our advantage will depend on the purpose which animates her in exercising her new influence. When the war is over, Japan's chief object will be to repair the waste and to set about improving her financial position.

This she can best do by building up a strong commercial connection with her neighbour, and finding in China opportunities for commercial and industrial development such as she has carried out with marked success at home. Natural advantages of position, and social affinity will give Japan much assistance, and make her a formidable rival, but the new fields to be opened will be accessible to all. If our trade with Japan has kept on growing concurrently with the great industrial development of that country, we may confidently look forward to also seeing it increase in China if Japan fortunately succeeds in making that nation follow in her footsteps.

DISCUSSION.

The CHAIRMAN said the audience had had the advantage of listening to a paper which from beginning to end had been replete with interest, and he felt sure they had reached the conclusion that alike as to ideas and suggestions it was worthy of the all-important subject with which it dealt. He also thought the illustrations shown on the screen had been admirable. The author had omitted very few facts and considerations necessary for the formation of correct impressions with regard to the present condition of British trade with China and its prospects, and in the points that he had touched upon lightly, doubtless for diplomatic reasons only, he had made many useful suggestions. Any complete unravelling of the tendency of things in China was, it seemed, practically impossible, owing to the complexity of the factors arising out of the development of the policies of foreign powers. But the author had said enough to show that they need not despair of the future of British trade and commerce in China, and he had also hinted that they were by no means confronted by any impossible problems or intangible solutions. At the same time he thought it was necessary to remember—and Mr. Brenan emphasised the point very aptly—that the British supremacy of former years no longer existed unchallenged, because foreign nations, in pursuit of their world politics as they understood them, were beginning to stand up to England and to dispute every inch of ground in which she used to be easily first. It struck him, with regard to the railway schemes, that there were two which had the greatest possible interest for those who were concerned in Chinese trade, *i.e.*, the line from Canton to Hongkong, which traversed a vast, populous, and fertile country, and that from Shanghai to Nanning, which also tapped some of the richest parts of China. With respect to shipping, large as was the English proportion to that of the rest of the whole world, yet they would more and more begin to feel that if England was to hold her own in that domain of enterprise she would have to wake up to the necessities of the situation. His own opinion was that their most formidable competitors in the near future would be their friends the Americans. He thought that if England was to have competitors in China it was fortunate that they were the Americans, because he made bold to say that in the orientation of the foreign policies of these two kindred nations, whether in the commercial, the fiscal, the diplomatic or missionary line, they saw eye to eye, and were in complete accord and agreement. He was rather glad to hear the cheer with which that remark was greeted, because he thought some present must be tempted to wish that in the matter of their home policy the Americans could equally see eye to eye with England, because who could fathom the vast potentialities or accurately gauge the possibilities of a world-girdling union of that description? It would be a great satisfaction to us to know that in the elaboration of American imperial aims, English methods of expansion would be followed, thereby strengthening the policy which made for Anglo-Saxon dominion in the Far East. He agreed with Mr. Brenan that in the interests of those who had no desire to grab territory in China it would be better if there were no partition of spheres of interest; but England, he feared, was no longer mistress of the situation. The partition of China took place three years ago. He hoped they had not let slip the golden opportunity that was presented to them when, in the course of that partition, the Yangtze Valley was given to England as her sphere of influence. Every important nation acquiesced in that decision, with the exception of Germany, who made what he considered a not unjustified reservation. She said, "We will agree to acknowledge the Yangtze Valley as your sphere of influence if you make it an effective occupation." He could not see that any special peril or risk was attached to the enterprise of making it effective, but some sort of diplomatic palsy seemed to have taken possession of English statesmen's minds. That rich and fertile valley, populated by the most peaceably disposed population in the world, appeared to have been made to pass under England's sphere of influence; the *Pax Britannica* there would have proved an untold blessing to the Chinese, and would have brought extraordinary advantages to English commerce and industry. All that was required was that several good gunboats should patrol up and down the Yangtze. He did not know whether English influence had lapsed there or become vitiated by our not having made the occupation effective, but it looked so from the free and easy manner in which Germany was acquiring railway, engineering, and coalfield rights, without the slightest reference to English views or interests. He thought Germany must have been surprised at England quietly allowing her to take all those concessions. If we had attempted similar liberties in Shantung we should very soon have found out that there were other masters besides the Chinese in that province. English policy in the Far East showed a certain amount of self-effacement, a waiting

upon events as they might shape themselves in accordance with the caprice and the pleasure of other powers. He could not imagine why it should be so. Surely it could not be because England was afraid of disturbing the European concert. He believed that concert to be an absolute sham, a snare and a delusion, because every power with the exception of America was going its own way, and was trying to work out its own salvation, irrespective of the views of the susceptibilities of England. As one interested in trade, commerce, and banking in China, he recognised Lord Lansdowne's eagerness to protect British interests, but could not help feeling that some sort of Palmerstonian mailed-fist was necessary at the present moment to assure our countrymen that, if they obtained any concession from the Chinese Government, that concession would be absolutely respected. The public were sometimes puzzled to understand the motives of our policy in the Far East. Could anyone explain why Lord Salisbury scuttled out of Port Arthur incontinently, an action which ended by despoiling Japan of the legitimate fruits of her victories, with the result that the present disastrous war was taking place in Manchuria? He did not know whether England received any compensation for that complacency towards Russia; he should think not, judging from Muscovite aggression on the borders of Afghanistan. But he only mentioned this matter to show how strange to the uninitiated like themselves must seem those occult manifestations of high State policy. The conclusion to which he had come after listening to the author's most able paper was that England had everything to expect from Japanese progress in the Far East; that Japan was very likely to join China in opening up her country and granting more facilities to the Chinese; and that if China could only be got to see that the benefit of her own people would be the benefit of her own Government, then he thought a very large stride would have been made towards the regeneration of that country.

Colonel MANIFOLD said he had been very much interested in the paper, particularly with that part which dealt with Ssuchuan, a province in which he had travelled a good deal during the past five years. It was probably one of the richest provinces in China, while its population was extraordinary. The author had referred to the prospects of railway communication in that province, and the fact that Mr. Brenan deemed it possible meant a good deal, because he had travelled extensively in that region, and had seen most of the difficulties of the country. There was no doubt that even if an easier route was not discovered than that by which Mr. Brenan had travelled into Ssuchuan, a railway line over any route not absolutely unpracticable would be a most profitable enterprise and also a most profitable undertaking for British trade. He believed the population of Ssuchuan was estimated by the Chinese at 75,000,000: the author said at a moderate estimate it would be 45,000,000. Captain Hunter and himself travelled through Ssuchuan in 1901-2; shortly afterwards they were at the Delhi Durbar, being on the staff connected with the manœuvres, and were thus enabled to see a good deal of the Delhi plain. Each of them had obtained statistics of the population of the Delhi plain, and found that the population was about 800 to the square mile. Comparing the Delhi plain in their minds' eye with what they saw of Ssuchuan, they came to the conclusion that the population in that province of China was considerably greater, and that Ssu-chuan, in many districts, must probably have a population of 1,200 to 1,500 to the square mile, which was far larger than on any agricultural area in Europe. He thought probably the author must also have noted the enormous extent to which India was interested in Ssuchuan. The trade which passed through the Customs Office, of which an accurate note was taken, amounted to about £2,300,000 per annum, which represented about one-fifth of the total trade of the Province of Ssu-chuan. Of that £2,300,000, £1,800,000 was in Indian cotton yarns, which came round to Shanghai from Calcutta and Bombay, and thence went up the Yangtse. A railway which would avoid the dangerous journey through the rapid the author had described would be of the greatest importance to India, and would probably lead, by means of extensions, to a linking up with Burma. Even in the present state of communication through the difficult channels, rapids and gorges, the Indian trade might be enormously extended. He thought everyone must agree with the author's remarks on the subject of railways in general, but unless England adopted a forward policy commercially the business would very likely pass into other hands; a sphere of influence would be set up, prohibitive tariffs and other side issues would be adopted, and, as a result, English trade would very seriously suffer.

Sir J. GEORGE SCOTT, K.C.I.E., said that in the previous September he passed up the Yangtze Valley and went over the Hankow and Peking (or Pe-han) Railway. From what he saw during that journey he could confirm the author's statement that English influence in the Yangtze Valley was declining, there being almost as many German steamers running from Shanghai to Hankow as British, and the number of Japanese steamers was quite as large. Under those circumtances he was afraid that English influence would not remain effective very long in the Yangtze Valley. The railway he had mentioned ran through the centre of the great plain of China, which was the most cultivated and populous part of the whole empire. Three hundred and eighty kilometres of the railway north from Hankow were open as far as Yen Cheng, and it was possible to get to the Yellow River in ballast trucks and waggons. When he passed through in September about 100 kilometres of the extension from

Peking south remained to be finished, but one could take tickets from Peking to Shun Tê, a distance of about 390 kilometres, and from there go in ballast trucks a further 150 kilometres. It had been announced within the last fortnight that the railway was finished, which he presumed meant that through carriages ran from Peking down to the Yellow River. The statement made by the Chairman that nothing had been done with reference to the bridge across the Yellow River was not correct. The proposed bridge was to be about two miles long, and the approaches on either side to the extent of probably half of the distance had been completed; but the most serious part of the work yet remained to be done. The engineers of the work, who were principally French, were not at all confident that the bridge could be built, owing to the enormous depth of shifting soil in the river bed. Forty feet screw piles were being driven into the river bed, and abutments, composed of enormous piles of rock and concrete, were being built; but from the experience gained on a number of rivers of a similar character in the country the engineers were not at all sanguine of the result, because after the heavy rains of the previous year a great many of the smaller bridges which were built on the system proposed to be adopted on the Yellow River had been very seriously damaged. When the railway was finished enormous quantities of goods would be landed at Hankow, but he did not think those goods would be carried in British ships. Ten years ago, when Mr. Brenan was last in Hankow, probably no French was spoken, but it was now the ruling language on the railway line. The engine drivers, the men in charge of the coolies, and the railway policemen all talked French, and while the railway was called a Belgian railway, nearly all the capital had gone into French hands. The French, Germans, and Japanese were very greatly undermining English influence on the Yangtze, and unless England built a railway from Burma and Shanghai, in answer to the trans-Siberian Railway and the French railway from Tonking, he did not think she would maintain her influence in the Yangtze Valley.

Mr. R. S. Gundry, C.B., thought everyone present would agree with the remarks the Chairman had made in regard to the political situation, and the regret he expressed that England stood aside, while France, Germany, and Russia were allowed to despoil Japan of the fruits of her victory in 1895. A precautionary clause guaranteeing the integrity of Korea and stipulating that, if Port Arthur were retroceded to China, she should never alienate it to another Power, might have gone far to prevent subsequent trouble. The self-abnegation (should he call it?) displayed in that case was followed by the still more remarkable withdrawal of British ships from Port Arthur at a moment when the Russian ships were under orders from St. Petersburg to leave, and if the British ships had stayed there another twenty-four hours, they would have found themselves alone. The present war between Japan and Russia seemed to flow directly from those permissions, just as all that Russia had done in Manchuria flowed from the Cassini Convention. A policy of spheres of interest or influence held the field for a period after the withdrawal from Port Arthur; and the impression was certainly conveyed to the people of this country that the Yangtze Valley had been secured as the English sphere. The first nail that was driven into that proposition was the giving of the concession for the Peking-Hankow railway to a Franco-Belgian company. The China Association, with which he had then the honour to be connected, addressed a letter to the Government when the question was at its height, suggesting that the concession ought to be secured at all costs for England if British interests were to be preserved in the Yangtze region, as it was altogether inconsistent with those interests that a great railway, built by Franco-Russian capital and supported by Franco-Russian diplomacy, should be driven down into the heart of the Yangtze, and that, inasmuch as private enterprise could not fight State-aided enterprise, the Government should guarantee $2\frac{1}{2}$ per cent. on the £5,000,000 required to construct the railway. The project did not find favour, and some of the consequences had been made apparent by the last speaker. The rival policies of "spheres of influence" and of "integrity and the open door" would be revived, probably, in the negotiations which would attend the termination of the present war. He imagined there would be a marked division of the Powers when that question arose, for certain of them which were interested in extending and strengthening their influence in China would be interested in letting Russia down as quietly as possible in Manchuria. In the other camp would be found England, America, and Japan, who had declared in favour of maintaining the integrity of China, and they should be strong enough, if they stuck to their determination, to carry it through. It was not a policy, however, which could be achieved by pious aspiration alone; a very decided opinion would have to be expressed if it was to be carried through.

Mr. J. D. Rees, C.I.E., remarked that the author of the paper had spoken of China after the present war accepting the guidance of the Japanese. That was really a very innocent statement; but he thought it was worth while getting from a speaker who enjoyed a reputation such as Mr. Brenan had, exactly what he meant by that statement. At the present moment, when Russia, crushed in the field and troubled with internal revolution, was at her wit's end to justify her conduct in any direction, a great deal was heard, even from those who should know better, about the Yellow bogie; and he should be glad to hear from the author that when he referred to China taking the advice of Japan, he did not contemplate any alliance between those nations for the purpose of making any hostile attack upon the West. Mr. Brenan well knew that

the Chinese and Japanese were no more likely to combine together to attack the West, than France and England were likely to combine to go on a filibustering expedition, to attack the East; in fact, the one was just as likely as the other. But, in spite of that, responsible organs, occupying a position in foreign countries similar to the position held by *The Times* in England, were constantly putting forward that statement as a possible fact, with the object of looking to the end when the powers would come in again to divide the spoils which they hoped to get at the conclusion of the present war. He himself had been called a "foreign devil" from Canton to the country beyond the Great Wall, but he had accepted the epithet as descriptive and not abusive. He was treated there with some kindness and consideration, and he was, therefore, glad to hear a paper in which China was not visited with unmeasured abuse and condemnation. He was roughly handled the other day in Scotland for describing Japan as a comparatively free trade country. It was a comparatively free trade country compared with its neighbours, China and Russia. The influence of Japan upon China would all be in the direction of free trade; it was not likely to have any other effect. He hoped the author would be able to state that that was the only respect in which he meant that China was likely to follow the lead of Japan after the war was over. He hoped every occasion would be seized for dispelling the foolish Yellow terror, which was being put forward simply in view of some unjustifiable arrangement for robbing Japan of her victory, as took place on a former occasion, when she was despoiled of Port Arthur.

Mr. BRENAN, replying to Mr. Rees, said that if his forecast turned out to be correct, and if China, accepting the teaching of Japan, embarked on a course of reform, and became, as well she might, even more powerful than her teacher, still in his opinion this need not cause any alarm to Western nations. Neither China nor Japan were ambitious in the sense of being aggressive. They needed to be strong for the purpose of defence; but neither Power, however strong it might become, would be likely to use its strength on our side of the world; it would be used for protecting the Far East from the encroachments of Western nations. Japan has been showing us how she can use her strength in this respect. It would not be surprising if Japan's success suggested to her the advisability of further increasing the powers of resistance by calling into life the latest forces of China, and effecting an alliance for mutual protection; and in the accomplishment of this design both countries had the speaker's good wishes. For China to become strong she must go to the expense of organising and maintaining efficient and adequate forces. The want of money for these purposes might stimulate her to adopt wise measures for the development of national wealth and prosperity; and a strong, wealthy, prosperous China had been the keynote of the speakers' remarks this afternoon. The Yellow peril need cause alarm to no one who had honest intentions towards China. The nations who had visions of a Yellow peril were those who liked to fish in troubled waters, and who looked on the Far East as a happy hunting ground. For these a Yellow peril would undoubtedly exist in an alliance between China and Japan, and in the interest of law-abiding nations it was desirable that the peril should exist.

The CHAIRMAN, in proposing a hearty vote of thanks to Mr. Brenan for his most interesting paper, said the author had elucidated one particular point on which they all wanted some sort of assurance, *i.e.*, that the advance of Japan and her progress in the commercial and military world betokened no kind of danger to any nation on the face of the earth. In replying to Mr. Rees's question, Mr. Brenan had assured them that, at all events in his view, there was no such danger looming before any nation.

The resolution was carried unanimously.

NINTH ORDINARY MEETING.

Wednesday, February 8, 1905; GEORGE DAVISON in the chair.

The following candidates were proposed for election as members of the Society:—

Allen, Caleb J., Hillside-house, Lancaster.
Allis, Edward Phelps, jun., Palais Carnoles, Mentone, France.
Bingham, Charles Henry, 13, Great Brunswick-street, Dublin.
Cloud, John W., 82, York-road, King's cross, N.
Colabawalla, Dinshaw D., care of Dr. Framroze C. Thanawalla, Aga-buildings, Bhendy Bazar, Bombay, India.
Johnson, Edward, 605, Salisbury-house, E.C.
Kelly, Alexander, 100, Hyde-park-street, Glasgow.
Llanos, Eduardo, 96, Leadenhall-street, E.C.
Parish, William Francis, jun., The Vacuum Oil Company, Ltd., 4, Norfolk-street, Strand, W.C.
Polden, Francis C., A.M.I.E.E., The Rhodesia Railways, Limited, P.O. Box 420, Bulawayo, Rhodesia, South Africa.
Schumacher, Harry A. P., 333, Calle Echaurren, Santiago, Chile, South America.
Sprague, Thomas Bond, LL.D., 29, Buckingham-terrace, Edinburgh.
Stuart-Fox, Julius J. S., The Western Telegraph Company, Ltd., Rio de Janeiro, South America.
Welbury, William, Middleton-crescent, Leeds.
Whittome, Philip Alfred, 23, The Chase, Clapham-common, S.W.

The following candidates were balloted for and duly elected members of the Society:—

Anderson, David, Ashdale, Satanita-road, Westcliff-on-Sea.
Childs, Harry, 47, London-street, Reading.
Dawbarn, Alfred H., 1, St. James's-place, S.W.
De-la-Motte, Freeman Alexander, Cadnant-park, Conway.
Gabbett, Edward, Public Works Department, Maymyo, Burma.
Hobhouse, Mrs., The Ridge, Corsham, Wilts.
Hyde, John, Lanier Heights, Washington, D.C., U.S.A.
Kodandaramiah, Khajana; Sompet, Ganjam District, Madras, India.
Macaulay, Thomas F., Rosbrien-house, Limerick, Ireland.
Mahler, Miss E., Sudworth, New Brighton, Cheshire.
Morris, Steven William Savin, P.O. Box 691, Cape Town, South Africa.
Munro, Laurence, Kronsbein-building, 10, Main-street East, Hamilton, Ontario, Canada.
Pottie, George, 42, Mansfield-road, Ilford, Essex.
Powell, A. H., Neston, King's-avenue, Ealing, W.
Rees, John David, C.I.E., 17, Pall-mall, S.W.
Sadler, Henry Knight, 5, St. Andrew's-place, Regent's-park, N.W.
Slessor, Major Herbert, R.M.A., Eastney Barracks, Portsmouth.
Smith, Harold Bayldon, A.R.I.B.A., 11, Constitution-hill, Port Elizabeth, Cape Colony, South Africa.
Straker, Donald, Haslemere, Surrey.
Waugh, Percival Bentley, Whitehall Club, Parliament-street, S.W.
Whitehead, Sydney, 24, Queen's-road, Wimbledon, S.W.

The paper read was—

TIME DEVELOPMENT IN PHOTOGRAPHY AND MECHANICAL METHODS OF CARRYING IT OUT.

By R. Child Bayley.

Time development may be defined as the development of the latent image in a photographic film regulated by the time during which a standard developer has been allowed to act, in distinction from development controlled by ocular examination of the result. I hope to show how it originated, to consider the objections to it and their cause, to discuss how far it is practicable, and to describe the mechanical devices at the disposal of the photographer who chooses to adopt it.

When this Society gave me the opportunity of bringing this subject before it, it was seized with no small degree of pleasure, because while much has been written and said concerning the controversial matters which underlie the subject, the practical outcome, so far as I am aware, the art—using the term as it should be understood in this room—has been to a great extent ignored.

Modern, even as photography goes, where the practices of ten years ago are old fashioned, we must still go back quite to the early days of the gelatine dry plate if we are to trace the growth of the principle which concerns us to-night, and especially if we are to understand the opposition with which so revolutionary a doctrine has been met, since that opposition is undoubtedly to be traced to the wet collodion process and its manipulations.

Photography with gelatino-bromide emulsions rapidly supplanted wet collodion in the early eighties. So quickly did the change take place, that we did not see the change of *personnel* that other sweeping alterations have brought about. The railway engine-driver was a totally different individual from his stage-coach predecessor; the linotype operator, as I can testify, is by no means of the same type as the compositor; the chauffeur is most certainly not a modified groom; but the dry-plate worker of those days was the wet-plate worker who had taken up a new process. He was the same man, working in the same place, with many of the same tools, although with a totally different process, and he came to the gelatino-bromide plate with a mind as indelibly marked with collodion ideas and methods as his fingers were with the silver bath. The consequences of his prepossessions are hardly yet shaken off, and it is to those preconceived ideas that we owe the fact that the principle of time development has taken more than ten years to influence to any marked extent the general practice of photographers.

Let us see for a moment what those prepossessions were.

The development of a wet plate was essentially a process of silver intensification. The exposed silver iodide and bromide were treated with a solution in which was silver nitrate on the verge of reduction, and it was by the deposition of metallic silver originally dissolved in the developer that the image of the negative was built up. There is no evidence to show that the silver in the silver haloid originally exposed formed part of the final image at all. It probably did, but it played a very small part therein, and the actual density was due to the silver applied after exposure in the

developer, or present during exposure in the solution the plate picked up while it was in the nitrate bath. Had the development of a dry plate been a physical intensification process of this kind, I should certainly not be addressing you to-night on this subject.

It is true we hear very little in the wet-plate days of the possibilities of correcting under or over-exposure by development (under-exposure has never been regarded as curable, by the way). This was due to a large exent to the fact that in the great majority of cases the work of development was performed immediately after exposure, and the simplest way of remedying any defect of that nature was to take a clean piece of glass and make another exposure. But the character of the negative could be very greatly modified by variations in its development, and the wet-plate worker came to the gelatine process expecting to find that he had as much control with it as before; and he was not apparently disappointed.

He was taught that if he had over-exposed, by the addition of a plentiful supply of an alkaline bromide to the developer he could so modify the results that it would be difficult, if not impossible, to tell an over-exposed from a correctly-exposed plate.

And this, no doubt, is perfectly correct. To the average photographer, a plate which has received four, or even eight times the exposure which it ought to have received, if developed upon the old-fashioned lines, gives a negative which by itself and without a correctly exposed negative with which to compare it, seems very much what it should be. But it is not by any means the same thing, as we shall see.

The reason for this belief is easily found. The most prominent characteristics of an over-exposed plate, developed as if it were correctly exposed, are a great density and fogginess over the whole surface. Instead of the image making its appearance gradually, the highest lights first appearing and getting denser and denser, until when development is complete they are very much more opaque than the shadows, we know we have a plate on which the image flashes up and the shadows begin to darken before the high lights have had much time to acquire density. By the use of a developer containing a considerable proportion of an alkaline bromide, this is to a great extent prevented. The developing process takes much longer, but in the end we get a negative in which the highest lights have as much density as we require; but thanks to the bromide, the deepest shadows, instead of being almost as dense, are nearly if not quite as transparent as if the negative had been correctly exposed. Such a negative gives a print in about the same time as if it had been correctly exposed; in such a print the high lights are as bright and the shadows as deep as we want them, and, superficially, the remedy for the over-exposure has done its work.

In the early days of the gelatine process, to put the matter in another way, the extreme ends of the scale of light intensities or densities were alone considered.

This can be seen in the Warnerke sensitometer, by which or by kindred appliances it was customary in those days to test plate speeds. A plate was exposed in such an apparatus in a series of steps, and the least light action perceptible was taken as a measure of the rapidity of the emulsion. Those who used the Warnerke sensitometer to any great extent and critically, soon found that, apparently, its readings were not always borne out in practice. Even to the eye, it was seen that of two plates used in the camera, one might do with less exposure than the other, although both gave the same reading in the sensitometer. It was therefore proposed, I believe by Mr. W. E. Debenham, that instead of taking the faintest perceptible image on the plate exposed in the sensitometer as the indication of its speed, we should take into consideration only those parts in which it might be said we had a printable image. In fact, as we should express it now, that we should deduce the speed of a plate from observation of the period of correct exposure. The advice was excellent, but it made the Warnerke sensitometer cease to be an instrument of precision. The last number visible, was a matter about which there could be little doubt; but the extent of the printable image was an ideal subject for unlimited debate; and the sensitometer used in that way, if it gave results more harmonious with actual practice, gave them only as the roughest approximations.

Such was the general attitude of photographers towards the subject of gradation during the eighties. Search as we may throughout the very copious literature of photography in those days, we find very little importance attached to truth of tone, very much to adequate contrast for printing. The trouble always seemed to be to get strong negatives, and the ideal put before the worker of those days was described in phrases reminiscent of the advertisements of a wine

merchant, such as a rich, a plucky, and even a "juicy" image. Captain Abney, it is true, had devoted some attention to the subject, as can be seen on reference to the 39th chapter of his "Treatise on Photography" (6th ed. 1890, Longmans), but little attention seems to have been given to his work. He noticed at any rate that "the tendency in all negatives is to cause a loss of gradation in the deep shadows as well as in the lights," a fact which will concern us very much later on.

In May, 1890, a paper entitled, "Photo-chemical investigations and a new method of determination of the sensitiveness of photographic plates," was read by Dr. Ferdinand Hurter and Mr. Vero C. Driffield, before the Liverpool Section of the Society of Chemical Industry. That paper, which it is hardly an exaggeration to describe as the very foundation-stone of the vast and still growing edifice of modern photography, laid it down as an axiom that:—"A negative is theoretically perfect when the amount of light transmitted through its gradations is in inverse ratio to that which the corresponding parts of the original subject sent out."

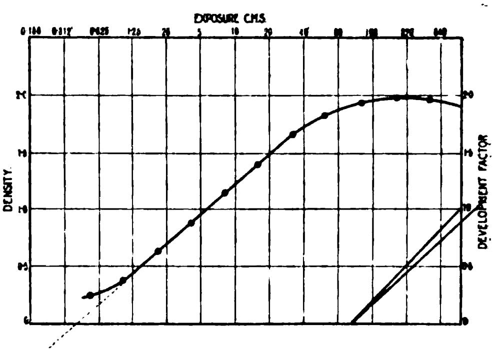
In the conflict which followed the reading of that paper I can find no trace of any opposition to the soundness of that view, and we may assume, therefore, that, as far as their definition of a perfect negative was concerned, it was accepted by photographers without demur.

The paper went on to describe a lengthy investigation made to ascertain the exact conditions under which such perfect negatives may be produced, and there also little of a contentious character was offered. It is only when we come to the subject of the development of under and over-exposed negatives that its authors raised a whirlwind of opposition and denial, but even that has now died down sufficiently for us to see how far they were accurate in their experiment, how far they were justified in their conclusions, and how far the work they then did has influenced modern photography. It is with that influence that we are now mainly concerned.

Taking then as a basis that "a negative is theoretically perfect when the amount of light transmitted through its various gradations is in inverse ratio to that which the corresponding parts of the original subject sent out," Messrs. Hurter and Driffield proceeded to show that given suitable conditions, such a negative was obtainable. Such a negative is one of which the densities are proportional to the logarithm of the exposures.

At a risk of going over ground that is familiar to you all, I will ask you for one moment to look at the diagram on the screen (Fig. 1), which represents what they termed the "characteristic curve" of a commercial plate. This curve has been obtained by giving the plate a series of exposures increasing in duration in geometrical progression, developing it for a standard time, in a standard developer, at a standard temperature, measuring the densities so obtained and plotting them in the way shown. The method of plotting is essentially a convenient device by which we can see at a glance to what extent the densities are proportional to the logarithm of the exposures, since in the case of a curve with densities as ordinates and logarithms of exposures as abscissæ, when any number of these are proportional the line joining them is straight.

FIG. 1.



These characteristic curves are now familiar to photographers, and more than one opponent of the views of the investigators who devised them have been obliged to express their results in the same way. The figure is a typical curve, which represents a well known and popular dry plate. It will be seen that the curve divides itself into four portions. First, a strongly curved part, where the exposures have been shortest, then a part which is practically a straight line, beyond that another curved part which takes us to the maximum density obtainable, and finally a descending curve, the reversal period, about which we need not trouble ourselves at present.

Messrs. Hurter and Driffield showed that so long as the entire range of exposures lies within the limits defined by the straight portion of the curve, the negative will comply, to a certain extent, with the conditions of theoretical perfection before mentioned.

They also ascertained by a series of experi-

ments, which have recently been repeated and fully confirmed by Messrs. Mees and Sheppard with a degree of refinement the original investigators can hardly have contemplated, that variation in development as practised by photographers has no effect whatever upon the density ratios of the negative. In other words, the straight part of the curve remains straight, however the developer might be modified, and the curved parts remain curved. When speaking of modification in the development, it must be understood that reference is made only to such modifications as were practised by photographers with the idea of remedying errors of exposure.

It is possible by complete alteration of the developer to modify the curve enormously, almost in fact, irrecognisably, but such methods are not of practical importance, and are rather of the nature of scientific curiosities. Given a developer which does not fog the plate, which is free from solvents of the silver salt such as ammonia, the only way in which the straight part of that curve can be modified is in the angle, which, when produced, it makes with the base line; it will always be straight, and it will cut the base line at the same point. Although, generally speaking, this remark holds good of alterations of the active developing agent, as well as of alterations in the strength and composition of a solution in which the active agent is always the same, there are certain developers, the use of which shifts the point of intersection very considerably. The result is that with these developers the plate is faster or slower than it is with others, a fact pointed out by Hurter and Driffield in their very first paper. Such alterations, however, are not used as methods of control, although, where the shortest possible exposures are demanded, photographers may use such a developer as will make their plates give a faster reading than the re-agent which they generally employ.

The variation which we do get by alterations in the composition of the developer, such as used to be recommended for the cure of incorrect exposure, can be effected by alteration in the time of development, in the temperature of the developer, and in the composition of the developer, or in two, or in all three. As it is always desirable, where control is to be exercised, that the control should be direct and simple, it follows that, since all the useful control we can effect can be got with variation in the time only, there is no need to vary the other factors, and one uniform developer, applied at a known temperature, will do all that we can require of it, provided the exposures have been correct.

Here then we have the basis of time development. The development of the plate is effected by a standard developer at a standard temperature, any control required being obtained by altering the time of development and that only.

Theoretically, we can alter the time of development in each case to obtain negatives to suit various printing processes, or to make different classes of subjects suitable to the same printing process, and to some extent this is done. Thus we hear of negatives being made "strong" because they are wanted for carbon work, or "kept thin" for enlarging. At the same time, it often happens that the result aimed at in this way is not attained, and many a photographer whose work is of a varied character, uses two or three different printing processes, so that he may be able to print a negative by the method best suited to it, whether that method was what he aimed at in development or not. The utilisation of the entire range of a printing paper is comparatively unimportant; and a negative with a development factor of 1·2, expressed in the Hurter and Driffield manner, if correctly exposed, will give a result by most printing processes (except perhaps by straightforward enlarging on bromide paper), to which the most captious would not take exception.

It is interesting to note, in this connection, that using the developing powders supplied by Kodak, Ltd., with Kodak film in the Kodak machine, to which I shall refer shortly, exactly as specified, gives us a development factor of 1·1 to 1·3.

This question of the development factor is an important one, as it is that on which there is the greatest degree of misconception. It has been urged against the proposal to develop for a fixed time, that a development factor that suits a portrait does not suit a landscape or an interior. Strictly speaking, this is perfectly true. In the same way, to get the best possible results, quantitative experiments have shown us that we require a higher development factor for negatives that are to be printed in carbon than for those that are to be printed in platinum, for platinum than for ordinary silver paper, and so on. But actually and in every day practice, the professional portrait photographer is the only worker who aims definitely at a result suitable for one particular printing process and that only. The average photographer, amateur and professional, aims rather at

an average result, he wants a negative which will suit him for any process he may fancy. Nay, more, he expects the same negative to give him a good contact print, and a good enlargement. Yet on the same printing paper, the former requires a very much higher factor than the latter, two-thirds as much again in point of fact.

To do this he must aim at an average result, and to tell the truth, a plate that has been correctly exposed and developed for such an average result, is so much better than nine-tenths of the haphazard results of incorrect exposure and "controlled" development, that those whose photography has merely for its aim excellent prints, and is not carried out with a nobler polemical purpose, are more than satisfied with it.

Such an average result it will be found is to be obtained by timing the development so that the factor is approximately 1·1, which it will be seen is not very far from the figures given by the Kodak method.

If we have a correctly exposed plate, and we develop it invariably in a standard developer at a standard temperature for a length of time to suit that particular plate, we shall find that it will give us a negative, not in every case as theoretically perfect as it could be made with more elaborate precautions, but a great deal more perfect than it could be made by any empirical procedure guided by mere ocular examination; and that not once but every time, with a minimum of trouble and a complete immunity from light fog.

So far I have been speaking only of correctly exposed plates. Let us now consider the question of incorrect exposures. The development applied to a correct exposure should be that best calculated to suit an under-exposed plate. For manifestly, if with much shorter exposure we could get the theoretically perfect negative by any modification of the developer, that would be the course to adopt in practice every time. No one wilfully throws away rapidity in an emulsion. And as a matter of fact it is so. An under-exposed plate developed by time as if it were correctly exposed, gives us the best possible result we can hope to obtain. Clear, but lacking in vigour, if the under-exposure is not too great, the plate can be intensified up till it attains sufficient contrast to print. It will never be a "perfect negative," either theoretically or practically; and I am not aware that any method of making it so has ever been devised.

The question of over-exposure is one which requires more consideration, because there are many photographers who believe that methods they employ enable them to determine during development whether a plate has been over-exposed or not, and if so, to remedy it so that in the final result the change brought about by the excessive exposure has been entirely counteracted during development, and the plate shall in no way differ from one correctly exposed and normally developed. The belief takes its origin in the old practice to which I have already referred, of judging a negative, not by the truthfulness of the whole of the gradations upon it, but by the visual appearance of its highest and lowest tones, by its clearness and contrast in short. The most obvious difference between an over-exposed and a correctly exposed plate, when both had been developed until the highest lights were equally dense, was that the former had much more deposit in the shadows, and, in consequence, much less contrast all through. A method of development which gave the plate contrast and prevented much of the blocking-up in the shadows, was supposed to cure the over-exposure.

The moment methods of measurement more accurate than ocular examination were applied to such negatives, it was seen that, so far from the over-exposure having been cured, its effects were as marked in such negatives as if they had been developed in the ordinary way. The density of the highest light and of the deepest shadow had been made to correspond perhaps with those on the plate that was correctly exposed, but the intermediate tones were as untruthfully rendered in the abnormally as in the normally developed plate. It is a curious fact that, while this method of "curing" over-exposure has satisfied that large body of photographers whose tastes are not sufficiently scientific to lead them to examine the subject for themselves, and whose artistic sense is not sufficiently keen to show them the essential falseness of the results so attained, I have known several workers, without the slightest claim to any knowledge of the principles of development, whose sense of tone value was sufficiently acute for them to detect at once that there was something wrong in these cases of fancied cure. They could not put their fingers on the cause, as we can now, but the symptoms to their trained observation were patent.

All the investigations of the last fourteen years go to show that over-exposure is not in

any sense curable by methods at present available. Prevention, says the proverb, is better than cure; and some of those who think it their duty to defend practices long since shown to be unsound, only do so by revealing their incapacity to grasp and employ preventive measures. If over-exposure cannot be remedied, the question still remains, what is the best way of dealing with it?

To answer that question, let me put another. If modification of the developer will not bring about the change we require, why should we modify it? The simplest and the most efficient plan to secure results from over-exposed negatives is to develop them for the same length of time and then either to print them as they are, which presents no difficulty with development papers, or to reduce them with such a solution as the ferricyanide and hypo reducer until they are sufficiently thin for the purpose required. But let me add once more that neither this nor any other device "cures" the over-exposure. It only makes the best of a bad job.

It will be seen, therefore, that the result of the investigations of exposure and development which so far have been carried out, points to two conclusions:—

1. The supreme importance of correct exposure.

2. The powerlessness of modification of the developer to remedy errors of exposure.

I hope that I have made clear that from these two conclusions we can draw a third, namely, that if all our negatives receive identical development, identical, that is, as regards composition of developer, temperature of developer, and time of development, provided that treatment is the best for a properly exposed plate, it is at least as good for all as any series of modifications can be.

So far, however, we have only reached the conclusion that it is as good as other methods. We will now see whether such a method brings with it any other advantages. Manifestly, if we are going to treat all our exposures alike, the need for some method by which we can watch the development of the plate vanishes. We neither have to determine from its appearance whether to modify the developer or not, nor when development is complete.

This brings two advantages in its train.

The risk of light fog, or rather the degree of light fog is reduced, because every plate developed in the dark room, as we know it, is fogged more or less, generally I am afraid, more rather than less. No light worthy of the name is "safe" for prolonged development; and although I am aware that such an objection may seem hypercritical, and my audience may know that in their own practice those of them who develop in the dark room get negatives to all intents and purposes free from fog, the enormous majority of the negatives which I see, and I see many hundreds in the course of a year, are fogged, and badly fogged, either from the dark room illumination, or from an unsuitably compounded developer, or from both.

Quite apart from the risk of fog, the determination of the point at which to take the plate out of the developer is a difficulty even with the most experienced photographer, if his only means of ascertaining it is by looking through the negative at the light. The apparent contrast obtained is not necessarily the actual contrast, since it is affected very largely indeed by the thickness of the coating of emulsion on the plate, and to a small extent by the brightness of the light by which it is examined. This latter may be made constant, but the former cannot; and although modern machine coated plates are remarkably uniform as far as any one batch is concerned, I have found considerable differences in the thickness of the coating on plates of the same brand but made presumably some days or weeks apart. When the conclusion of development is settled by the clock these sources of error disappear entirely, and hundreds or thousands of plates can be developed with a degree of uniformity which is to be attained in no other way.

It is for these reasons that a good many years ago now I became a convert to the method of working known as time development. Its advantages may be summarised thus:—

1. It gives us perfectly uniform negatives when exposure has been correct, whether we develop daily, or only have a few to deal with every now and again.

2. It brings everything out that can be got out of an under-exposed plate, and removes the temptation to over-develop in the hope that more details may be obtained.

3. It gives us as good a result as can be got with overexposed plates, and prevents any risk of insufficient development which may be caused by the difficulty of judging how far development has gone when the plate is very opaque.

4. It reduces light fog to a minimum, and in the case of roll films does away with it entirely.

5. It overcomes entirely the difficulty of determining when development is complete.

6. It can accommodate itself to the nature of the subject or to the printing process to be used, or may be settled once for all to give a good "all round" negative.

Modern Mechanical Methods of Time Development.

I now reach the second portion of my paper, which deals with appliances for time development. Before referring to them more specifically, it would be well to point out that there are two distinct systems by which time-development can be accomplished. In one, we note the time taken for a certain part of the image to make its appearance, multiply that time by a factor which depends upon the developer used and the development factor at which we aim, and take the result as giving the time of complete development. This is the Watkins system, and as it has already been brought before this Society by the gentleman best qualified to deal with it, I need not, to-night, go over the ground already covered by Mr. Watkins, but will merely refer to the *Journal of the Society of Arts* for December 5th, 1902 (vol. li., p. 42), in which his paper will be found.

Before leaving Mr. Watkins's system, I would like to make one more reference to it. It has been urged against his method of development, that it results in under-development of cases of over-exposure, and if his rules for development are rigidly carried out without exception, there is no doubt that this is the case.

It has been foreseen by him, however, for in a passage in his book which describes his method, speaking of over-exposure, he says (p. 82) "it is, perhaps, even a better plan to develop half as long again, and afterwards reduce with the ferricyanide reducer, which reduces the lower tones more than the upper." It must never be forgotten in considering the Watkins method that it is one which deals both with exposure and development; and that those who master his system and bring merely an average degree of intelligence to bear upon its application to their own practice, will not know much about over or under-exposure except what they read.

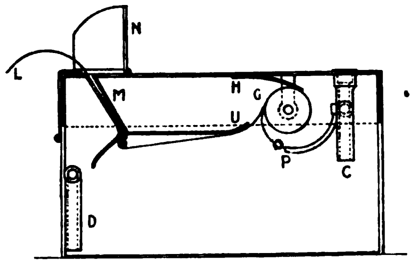
In the other system, a definite developer at definite temperature is allowed to act upon the film for a definite time, no inspection of the image being necessary, nor indeed with some forms of apparatus, possible. This is the method adopted in the "Tyma" and in the "Kodak" developing machines, examples of both of which are before you.

The "Tyma" machine, which is the invention of Mr. Max Reichert, was patented in 1901 (No. 14079), and was the first time development machine to make its appearance on the British market; having originated, so its inventor informed me, from an editorial article of my own, written and published in *Photography* in the previous year. It is a curious fact that, so far as my examination both of British and American patents has gone, the "Tyma" is the one and only mechanical apparatus for time development for which protection has been granted, if we except the various forms of automatic photographic machine in which the principle had necessarily to be employed, but in which the development was only one incident in a series of automatic operations. Even the best known, and certainly the most ingenious of machines, the "Kodak," as we shall see later, was protected, not as a machine for time development, but with the necessary window and peep-hole for examining the progress of the operations. For a good many years there have been quite a number of patents granted for enclosed dishes or stands in which development can be carried out, but they all provide for the necessity of watching development. In fact, they are simply little dark rooms, outside of which the user remains and watches through a ruby glass what goes on. Yet the patentee of the "Tyma" in his specification talks of "the well-known principle of time development." The "Tyma," however, has fallen from grace, and in the latest pattern, which is on exhibition, it will be seen that it is provided with a sliding shutter which covers a ruby window, although this cannot be of much service as the opening is along the edges of the film.

The two diagrams now on the screen (Figs. 2 and 3), are taken from Reichert's specification, and will serve to make the working clear. One or two minor alterations have been made in its general design, for manufacturing purposes, but it is still essentially what is now seen in these slides. It consists of a metal or other box, with a light-tight lid. In the box and lid are three openings, D and C, circular tubes for the passage of the solutions, and M a flat tube practically the width of the box. The way in which the film was immersed was a very ingenious one, and in my own practice—and I used the "Tyma" for some little while with perfect satisfaction—never failed. The spool of film with its black paper was placed

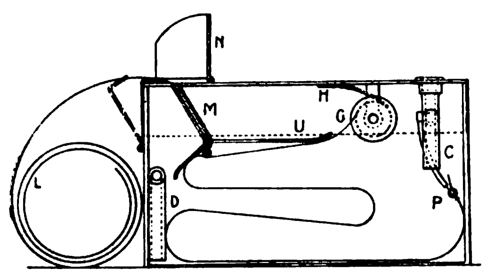
on trunnions provided for the purpose at G. The black paper was unwound a little, H being a spring to prevent the spool from unwinding too readily, and was led along under the finger or guide U and pushed up through the flat tube M until it came out of the top; N is a little flap which is raised while the black paper is first put through, and is pressed down again so as to serve as a light trap as soon as

FIG. 2.



there is enough at L to catch hold of; P is a little clip, in which the extreme end of the sensitive film is gripped. All these operations are performed in daylight and very easily, as the various parts referred to are all attached to the lid, which can be removed and turned up side down for the purpose. Then, as much water as can be poured in without causing the syphon to operate is put into the body of the apparatus, and the lid is put on. We then have the state of things shown in Fig. 1,

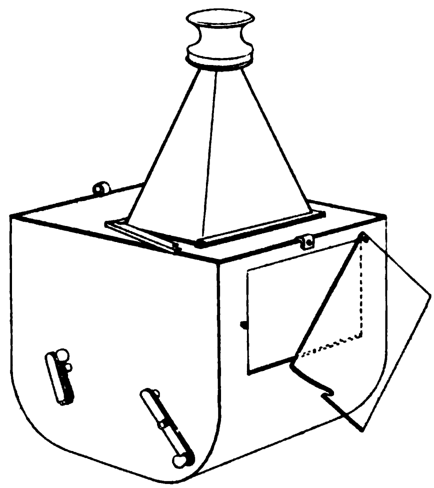
FIG. 3.



except that the flap at N is closed. On pulling the end of the black paper L the spool unwinds, the black paper comes out of the box, and the sensitive film, film side uppermost, forms a series of loops below the surface of the water. When the end of the film is reached, being attached to the black paper it enters the tube M, where by a contrivance for the purpose, the extra thickness of film and paper jams, the photographer knows that his spool is all unwound, and the film is held for the subsequent operations. These consist of syphoning out the water, pouring in a definite developer for a stated time, gently rocking the tank meanwhile, syphoning off the developer at the end of that time, and washing and fixing the film in a similar manner, when the lid can be taken off and the film removed for the final washing and drying.

The same inventor has made a machine for plates, but this need not concern us, as no mechanical methods yet devised for them enable us to do away with the dark room, or indeed present any noteworthy advantages over an ordinary dish provided with a light-tight cover, which is what I use myself for such work.

FIG. 4.

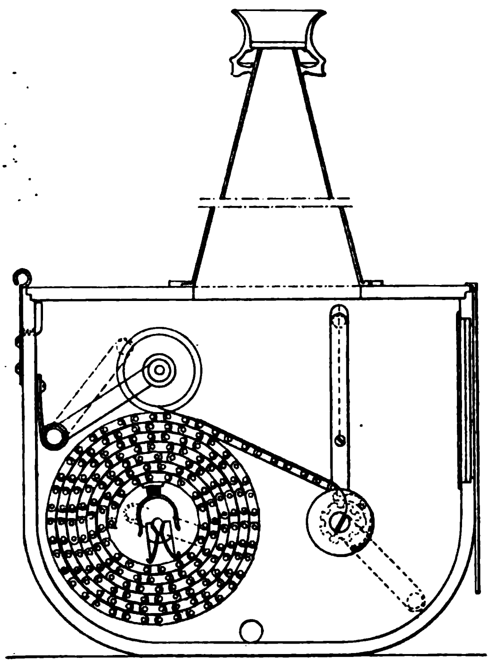


We now come to an instrument which is, I expect, well know to everyone in this room—McCurdy's patent apparatus—which has evolved into its latest form, very different from the original one, the "Kodak" developing machine.

The slide now on the screen (Fig. 4) shows the external appearance of the Kodak developing machine in the form in which it was protected by McCurdy (Patent No. 21243, 1899). You will observe that while it is a very different affair from the machine as it now comes on the market, there is more than a suggestion of it, both in general shape, in the two spindles with external handles, and in the chain which subsequently developed into the well known celluloid apron. The internal structure is shown in the next slide. (Fig. 5.) The stages in its development which intervened between the granting of McCurdy's patent and

the machine as we know it must be imagined. By the courtesy of the Kodak Company I am able to show you one of the earlier experimental forms, in which we see the machine practically ready for that manufacture on a large scale which has since resulted.

FIG. 5.



The next slide (Fig. 6) is copied from the book of instructions and shows the machine as at present made with part of the front removed to allow the interior to be seen. The apron, F, is made of ruby-tinted celluloid, of the same

FIG. 6.

material in fact as the Kodak film itself, but with a red colouring matter added. Along each edge of the apron are corrugated rubber bands which keep each coil of the helix distinct, and allow the fluid to circulate between them. The apron being rolled on the left-hand spindle, the roll of the film is put into the position shown, the black paper is inserted into the slot on the spindle, G, and is wound round it until just before the film itself begins to come off the reel. The end of the apron is then hooked on to the spindle, G, half a turn is given to the handle to secure it, the developer is poured into the right-hand receptacle, the lid is put on and the handle slightly turned. It goes stiffer and stiffer until at last the whole of the apron is on the one spindle, when turning again becomes easy. Inside the right-hand half of the machine we then have what is to all intents and purposes a very long shallow dish, the bottom of which is formed by the apron, and the sides by the corrugated rubber strips and the sides of the machine itself. This dish is coiled in a helix. On the bottom of it is the black paper and on that lies the film, face outwards of course, which is exposed to the action of the developer.

We are told to turn the handle slowly, about fifty turns a minute, until the development is complete. At the first glance we might suppose that by so doing the film is carried through the developer much in the same way as it might be in the old style of developing long lengths of films by see-sawing it through a small dish; but it is not so. There seems to be no doubt that the developer is carried round with the film except for a slight lag. That this is so, is confirmed by an experiment which shows that the development factors for exposures developed close up to the spindle G is not appreciably different from that of exposures developed right at the periphery; although, of course, were the liquid stationary and the film dragged through it, we should expect the latter to be higher, since rapid motion of the developer on the surface of a film or plate, such as can be got by violent rocking, always tends to give a higher development factor.

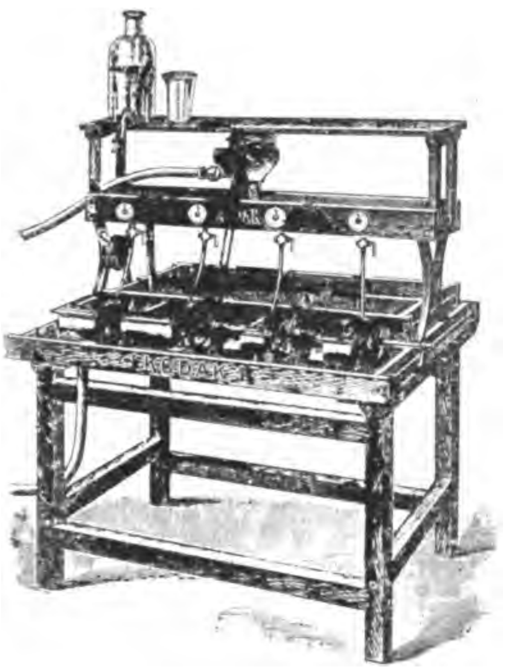
Of late years my experience has been gained entirely with a machine of this type, known as the pattern E, and taking any width of spool up to five inches. I have never had any failure with it which I could attribute to the machine, and although I have developed some hundreds of exposures in it, it is, so far as my observation goes, as good as when I had it; nor has it required any adjustment.

The next slide (Fig. 7) shows a combination of four machines with a water motor, such as is supplied for trade purposes. It is used extensively, both by Kodak, Ltd. and others for regular trade development, and is not only found to give as high a percentage of good negatives as the old plan did, but gives besides

complete immunity from light fog, finger marks, and so on, and a very great economy by the substitution of ordinary for skilled labour. Rumours of further improvements of the machine are in the air; but nothing definite has yet been announced.

The makers of the Tyma and of the Kodak developing machines both supply developers suitable for use with them. Those who use the Kodak packet developers which are pyro soda, have the advantage of knowing definitely the composition of the solution they are using, and of a "time-table" which is given in the instructions, and gets over the temperature difficulty very simply. The developer recommended is made up so that each ounce contains approximately:—

FIG. 7.



Pyro	$1\frac{3}{4}$	grains.
Anhydrous sodium sulphite	10	,,
Anhydrous sodium carbonate	7	,,

The time-table recommends developing for eight minutes at 45° Fahr., five minutes at 60° to 65° Fahr., four minutes at 70° Fahr., development not being advisable above 70° Fahr. In actual practice I find it simplest to bring the developer to 65° Fahr. by pouring it into a jug that has been warmed with hot water, if need be. It has been urged against this system that the temperature of the developer when development is finished may be very different from that which was ascertained with the thermometer before commencing. It *may*; but the objection hardly applies to ordinary usage. To get definite figures on the subject I took the temperature of the room and of the developer before and after use during the cold weather last week. The room was 55°. The developer was put into the machine at 65°, and after development was still between 63° and 64°. That was in a cold room. My developing is generally done in a room at 60° to 65°, when of course the difference would be less or would disappear altogether.

There is no need to use the formula given by the makers, of course, provided we find out how long development must be with the selected developer in order to give us the development factor desired. This can be got near enough for most people by developing a few cut films in a dish and noting the time taken for the exposures which seem to be about right to reach correct printing density, noting also the temperature. That temperature and that time will then be approximately what is required. Such a developer is the following, which I have found very suitable for Kodak films. It gives an image that is a little blacker than the pyro-soda formula:—

Pyrocatechin (Katchin)	2	grains.
Crystalised sodium carbonate	24	,,
Crystalised sodium sulphite	24	,,

The time of development with this formula, using Kodak film, and a temperature of 65° Fahr., is seven minutes.

When development with this machine is complete, the lid can be slid back, the developer poured off and replaced by water, this replaced by fixing solution, and so on in a way I need not describe. The whole of the operations can be performed in full daylight without the slightest fear of fogging the film.

I have used some of the other films on the market in the machine, and have found no difficulty in doing so, except that a gummed label or something of the kind must be employed to attach the outer end of the film to its black paper. In the case of the Wellington non-curling film, which in other respects has given me excellent negatives in this way, I have had trouble with the black paper sticking to the gelatine-coated back of the roll film; but I understand from the makers that this is having their attention.

There is one other little piece of apparatus which I have found very serviceable in connection with the developing machine, and that is Stanley's dark room clock, an example of

which is on view. It is convenient for many other photographic purposes, and is as handy a tool as I have in my dark room.

There are other pieces of apparatus which are on the market, which allow of plates being developed in the dark, such as troughs with lids and so on. Some of these have been lent by the makers and are on view. As, however, they involve no mechanical devices which do not explain themselves at a glance, I need not do more than allude to them in passing.

The Future of Time Development.

There is sound wisdom in the advice "never prophesy unless you know," and I propose to be guided by it to-night, and I will refrain from asking you to contemplate a vision of photography in twenty years' time, when all developing is done by a mechanical and not by a human "crank." I will ask you to remember, however, how great a change has come over the procedure of the photographer since 1890. It is not a change of apparatus or material so much as a change of method. One by one we are abandoning the old system, according to which we relied upon development to correct errors in exposure, and upon the eye to tell us when development was complete.

The motto for the future seems to be, "Take care of the exposure, and development will take care of itself."

Hurter and Driffield, Watkins, Wynne and others have made the problem of correct exposure far simpler than it used to be; plate and film makers are marking plates with far more definite information than the old "thirty times" or "fifty times"; and the plates themselves, thanks to improved instruments for studying emulsion making and the changes which take place during the growth of sensitiveness, are far more in accord with practical requirements. The sale of fast plates at a higher price than slow ones, such fast plates being only the slower emulsion unintentionally fogged, is inconceivable now; yet we are assured that not more than fifteen years ago it was the case. There are still some it would seem who are inclined to dispute the power of a developing machine to deal with under or over-exposure, but, with the advance in means of ascertaining what is the correct exposure, this objection, were it to have a foundation in fact—and I have endeavoured to show that it has not—would have to disappear.

Time development in its broadest sense is unassailable. The moment truth of gradation becomes all important, time development becomes a necessity; it can only be dispensed with so long as we have no means of testing the results. Skilled three-colour workers tell us that it is impossible to determine the duration of correct development with the eye. They must work by time development, quite apart from the fact that their plates are red sensitive. For studio work, where conditions are fairly uniform, something very much like time development is employed almost unconsciously. The operator who had to treat his negatives with tentative and all the other forms of development which figured so largely in the text-books of twenty years ago, might not find his methods traversed, but would certainly hear from his employers on the subject of his output.

For press work, the developing machine has already come extensively into use; it is employed, as the advertisements of its makers remind us, at the seat of war, at the Panama Canal, and elsewhere, under circumstances that would render the old-fashioned style of development impossible.

For pictorial photography, its convenience would commend it, if the truth of its results should not. One of the most gifted of photographic picture makers has said that a photographer using his camera as a means of artistic expression should no more have to think of his apparatus than a writer has to think of his pen. That degree of simplicity I fear is not attainable; but it can be approached, and a very distinct step is taken when we recognise that as far as the personal factor is concerned, our negative is completed when the exposure has been made; and it is on the recognition of that fact that time development is based.

DISCUSSION.

Mr. Chapman Jones said the author had divided the paper into two parts, in the first of which he (the speaker) did not think he had gone even far enough. We should not be content with the production of the negative, and then leave the print out of consideration. In almost all cases any error in the negative was exaggerated in the print, so that a perfect negative rarely gave a perfect print, *i.e.*, perfect as compared with the original subject. The second part of the subject was, he thought, a matter of profit and loss. The author had

represented the methods of time development as if they were all profit and no loss, and for his own part he sympathised with men like Mr. H. W. Bennett who claimed that there were distinct advantages in continuing to work on the older methods. The nett result of the profit and loss must depend on circumstances, but he was prepared to go so far as to say, that he believed there was not one man in ten thousand who would find that the nett results of using time methods of development were not profitable. He had seen people who did not know anything about photography use time developing machines; he had seen photographers use them, and had used them himself, and he believed, under ordinary circumstances, better results were obtained by developing so than by the ordinary methods. If the negatives were developed separately, some would be better, but he felt sure that the greater number would be inferior, except in a few cases where a man was particularly skilful. There were a few such men still living, who were doing work of a certain kind in which they had a great deal of practice. He would like to give one example where a positive improvement could be obtained by developing separately. If it were taken for granted that the exposures were all perfect—and they ought to be very nearly perfect under modern conditions—then it did not much matter how one developed so long as the negatives were not over or under developed. But if the exposures were not perfect, or if one did not develop completely (and he believed good photographers very rarely developed completely—*i.e.*, they did not develop out from the negative all they had put in from the exposure), there would be some negatives which might have been improved by a variation from the standard time. On the other hand he remembered very well developing a series of exposures in a "Kodak" developing machine, and thinking he knew better than the instructions. He gave them a minute extra, and afterwards wished he had not. He quite agreed that the advantage was all on the side the author had advocated, but there was another side, and there was perhaps one man in ten thousand who could take advantage of certain possibilities with regard to the time of development, and also with regard to the nature of the developer.

Mr. J. STERRY remarked that the author had spoken of there being no fog with time development. There would be no light fog because there was no light, but there might appear to be a fog simply due to a difference of exposure. Taking a plate thickly coated, which would give a correct exposure with one, two, and four seconds exposure, the result, when developing for a given length of time, must be different, and he believed that was the main reason why time development had not been taken up so rapidly as one would have expected. The only difference under the circumstances he had suggested, was that there was a fog over the whole plate, and the difference in printing would simply be a question of time. One could not altogether judge by the appearance; there would still be a visible fog which was not due to light but simply to the increased exposure. If the author had exhibited the actual negatives, an apparent difference would have been discernible in them which was not shown in the slides.

Mr. HECTOR MACLEAN congratulated the author upon the interesting and masterly way in which he had treated the subject. He was sure those present would sympathise with those gentlemen who, in the past, had been in the habit of mixing their developers with brains, and controlling their development with what he might term a kind of essence of artistic temperament. He had the pleasure of listening to Mr. Bennett's paper on the previous evening at the Royal Photographic Society, and that gentleman particularly emphasised the value which he considered he possessed in controlling the growth of his negative by ocular inspection, and also by wholesale variations in the strength of his developer. He would like the author to say whether it was possible to use the time system of development when the developer was diluted as much as Mr. Bennett said he frequently used it, *i.e.*, by the addition of eight times the amount of water usually employed under normal circumstances. When anything new was brought forward some people were inclined to imagine that everything which had preceded it was thereby entirely swept away, and it was sometimes by claiming too much that too little effect was gained by what was in the present instance a very valuable system of obtaining excellent pictures. He therefore thought that the very great importance of climatic influences in the development of the negative should be borne in mind. Everything would work smoothly if the temperature was fairly normal, but it was well to remember that questions of temperature, even with experienced workers, had brought about great disaster. For instance, negatives had, through too low temperatures, been under-developed, whereas, on the other hand, when working in the tropics, negatives had, when time alone had been used to gauge the development, been excessively over-developed.

Mr. W. THOMAS thought the subject was an eternal one, of which there was absolutely no solution. Those who believed that they could alter the results in their negatives by adopting various means were convinced of it, and gave what to them was a final answer, that not only were they convinced of it, but they had in their possession, as a result of their own labours, actual facts which demonstrated it. In fact, they could make out quite as strong a case in theory as had been made out on the other side by the author. The solution of such a matter was the actual

results produced, not in the shape of negatives, but of positives. The negative was only an intermediate stage, and whether it was fogged or clear, thin or dense, was perfectly immaterial. He did not agree with the remarks which had been made about the poor, wretched people who ought to be sympathised with. Mr. Maclean had stated that they mixed their developers with brains, which assumed the fact that they possessed brains. He did not think any sympathy was needed on one side or the other. The time was rapidly approaching, if it had not already arrived, when the question of mere length of exposure, or correct form of developer, would be perfectly immaterial, because neither by one means nor the other, nor the two together, could an absolutely correct representation and reproduction of natural objects and natural colours be produced on the plates at present in use. In considering the question of exposure and development there was a more important factor still to be taken into consideration, namely, the possibility of a present-day plate being amenable to treatment for the proper reproduction of the huge number of colours that had to be produced. If the plate was not quick and sensitive enough to enable photographers to get a full registration of some of the rays of the spectrum on the plate, no form of developer or development could possibly give a correct reproduction of it; and he hoped the attention of investigators on the subject would more and more be given to the production of a plate whose sensitiveness to the less actinic parts of the spectrum would be as far as possible raised, and at the same time its excessive sensibility to the blues and violets decreased, so that the two ends of the spectrum would be brought closely together. That was to some extent obtained at the present moment by using coloured screens, but he thought the question could not be definitely discussed as a complete whole within the mere confines of the exposure and development of the plate. He agreed with one thing in the principle described, that it would be by no means a bad plan if all beginners were simply given some form of developing apparatus, and were not allowed for a time to vary either the constitution of the developer or the time a plate or film was subjected to it, and by that means learn what was really the crux of the whole question; to give a full and ample exposure to every plate or film, because what was never on a plate no developer or form of using it could possibly put there.

Colonel ALLAN CUNNINGHAM presumed that when the author stated that the developer should not be used at a temperature of over 70° he spoke of the temperature of the developer itself, not of the air. The question, however, was one of considerable climatic difficulty. England was liable to a large range of temperature; in the States temperatures far below zero were common, while in the tropics temperatures over 100° were not unusual, and it was not easy, without ice, to cool water to a temperature of 70° when the air was over 100°. The author had made out a very strong case for time development, because there was no doubt that from a business point of view a much larger quantity of films and plates could be developed by the process than with the older method; but was it possible to get the best results artistically in that way? It seemed to him that the crux of the whole question was the exposure. If photographs were not developed for some months afterwards, one did not know whether they had been sufficiently exposed or not, and if they were then developed by the time method one had no control over the film or plate. He thought there must be many cases where it would be worth while saving an incorrectness of exposure by paying great pains to the development. For instance, one might be at a place which they would never visit again, and take some negatives of a scene which they were particularly desirous of possessing, and if one developed them mechanically the negatives might be lost, whereas if one developed them under control a result might be obtained which, though not so good as if the exposure was perfect, was still a better result than if a mechanical process of development had been used.

The CHAIRMAN said that Mr. Maclean was afraid that in hastening to the new they might be letting go something which was valuable in the old, but he thought Mr. Bailey had met that by pointing out that time development had been going on for ten years, and yet there were certainly thousands still tinkering with the developer, with their No. 1 and No. 2, with the idea that they were improving the quality of their picture, or counterbalancing over or under-exposure. If such tinkering was largely a delusion, it was of the utmost importance that those who were engaged in that practice, either in business or for pleasure, should be set upon a truer line, and that alone would be a justification for fully ventilating the subject very frequently. He admitted from his own experience that at one time he thought the variations in developing were infinite; in fact, he believed he unfortunately used that expression at one time. So they were in a certain way, but the delicate changes that were in practice, brought about by variations of developer, were not appreciable in the final print. It was the fairly wide latitude allowable in exposure, temperature, and time of development which made the machine method a really practical and useful one. He had heard a friend of his, Mr. Pringle, say that if there were no development by personal inspection in the dark room photography would have no further interest for him. He thought that was a state of mind which an enthusiast got into from long practice, because looked at from the point of view of anyone newly entering photography, the dark room could only be viewed as a discomfort and an enemy to good health. The point of view of the picture-maker had been referred to once or twice. Looking back upon his own experience, when he remembered the time he had spent

in the handling of 20-inch by 16-inch plates under circumstances of discomfort, when he might have put them into a dish, sat comfortably by them, rocked them for a time, and then taken them out and put them in the hypo, he felt that a good deal of it had been wasted. The photographer had to get some approximate idea of exposure, but even there the latitude was very wide with anything like a good plate or film. As Mr. Thomas stated, one had to think of the finished prints rather than of the intermediate stages. The photographer certainly had to get his lighting right, whether for figure, portrait, or landscape studies; he had to get every condition right, to know what he wanted, and know the means of getting it. He thought the time development system was most valuable for him, as indeed for every photographer, whether beginner or expert. There was considerable latitude in regard to temperature also, and the differences of temperature could be counteracted by altering the time given the development, as pointed out by Mr. Bayley. It seemed to him that if one had to be perfectly correct as to the exposure of the plate or film used, as to temperature, time of development, and character of developer employed, it would be very nearly as bad as having the discomfort and the unhealthiness of the dark room, but fortunately that was not so, because there was such a very wide latitude. To illustrate this, he wished to exhibit two frames, containing a series of four prints made from four negatives on a rollable film which had been developed in the developing machine for five minutes. The aperture of the lens used in every case was the same, but the plates were respectively given ½, 1, 2 and 4 seconds exposure. The only appreciable difference when the plates were developed was a variation in the general density of the negatives. If there was any variation in the gradation, it would be seen that practically the result in the print was the same. The number of seconds which each negative was given for printing on bromide paper was respectively 15, 30, 55, and 95 exposure to gas light. It was considered that about one second was the correct exposure of the subject, and most people would agree that that was slightly the best print, but the difference was so inmaterial that it showed what a wide latitude there was, and how valuable and reliable time development might be.

Mr. Bayley, in replying to Colonel Cunningham, said that whatever the temperature of the air might be in cold countries, the inhabitants did not live in rooms where the temperature was zero, and photographic developing was carried out in rooms which were heated. He could not imagine in the United States for instance, that there would be any difficulty in finding a room heated to 65°; in fact he thought there might be some difficulty in finding a room of so low a temperature. Where the temperature was 100° or over, there was a difficulty in developing at all because of the danger of immersing gelatine, which was soluble in warm water, in warm solutions; and the difficulty would apply equally to the man who developed in the dark room as to the man who developed by the time method. The difficulty could probably be obviated by the use of ice. The caution he mentioned, that the developer should not be used at a temperature over 70°, simply meant that it was not advisable to use warm solutions; but where the air was above 70°, and there were no means of getting it down to 70°, the precautions advocated in hot countries must be adopted, whatever system was used. He was not quite clear what Colonel Cunningham meant when he said that if he had only one negative of some valuable subject he would not like to entrust it to the time system of development, because it might be a failure, whereas he could save it by adopting some other method of developing. The whole purport of the paper was intended to show that if one possessed a plate of something which could never be taken again, as good a negative would be obtained by developing it in the time machine as by developing it in any other way, and the chances were it would be very much better. He would not say anything about the artistic result, because he did not see what it had to do with the particular method being discussed. Photographers were simply concerned in getting the most theoretically perfect negative, and they left it to the artists also to get as theoretically perfect or imperfect results from their negatives as they could get. Judging by the results of many artistic photographs he had seen, the actual character of the negative, or even the existence of the negative, was comparatively immaterial. One speaker had blamed him for not showing the negatives, and another for dealing with negatives rather than with prints. He thought those two objections might be put one against the other. He quite agreed that the print, or the final result, was the ultimate aim, and that, provided the right thing was obtained, it did not matter very much what the negative was like. He also agreed that if the right negative was obtained, and they were not able to get a good print from it, the system of obtaining the negative must not be blamed. In that respect he was not able to follow Mr. Chapman Jones, whom he understood to say that the theoretically perfect negative was not the negative which gave a perfect print. He was not aware of the experimental evidence on which that statement was based, and should be glad to see it. Mr. Chapman Jones had referred to certain circumstances where development was not complete. Of course if development was not complete enough to bring out all that light had done on the film as far as mere quality was concerned, any system of development would fail, but a system of time development which was not properly thought out was not one which he would justify for a moment. It was essential to any system of time development that it should bring out anything that it was possible to obtain from an under-exposed plate. If a system

of development did not give a perfect negative, and was too violent for the result obtained, then the operator was over-exposing. He did not think there was much in that, for the reason that most under exposed plates were spoilt was that, long after everything that could be got out of the plate had been obtained, the photographer had gone on strengthening his developer, thinking that possibly if he only went on long enough he might get something else. If, instead of doing that, he gave it the same development as a rightly-exposed plate, he would have the satisfaction of knowing that he had given just as much development to the plate as it would stand; he would get out all that was to be got out from it, and, at the same time, he might be confident that he had not fogged the plate through any fault of his own. He quite agreed with Mr. Sterry's remarks. There was no doubt that the essential difference between a plate which was correctly exposed, and another which was incorrectly exposed, was that there had been a fog put over the whole of the exposures, which could be subtracted when measurements were being taken, but which, when the printing was done, had to be printed through. He was sorry he did not say anything about orthochromatic photography, but he did not consider it came within the scope of the paper. Had he ventured into the thorny path of true colour reproduction in monochrome, there would not have been much room to discuss time development. The subject was very important, but it did not affect the system he had described one way or the other. By the time a plate was obtained which would give a perfect rendering in monochrome, everybody would be converted to the time method of development; in fact they would have to, because no light in which the plate was developed could leave it free from fog: some system would have to be used by which the plate was made and developed in absolute darkness.

On the motion of the CHAIRMAN, a hearty vote of thanks was accorded to Mr. Bayley for his valuable paper, and the meeting terminated.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock:—

FEBRUARY 15.—"The Decline of the Country Town." By ARTHUR HENRY ANDERSON.

FEBRUARY 22.—"Some Misconceptions of Musical Pitch." By JOHN E. BORLAND. (*a*) *Visual* —due to conventional but inaccurate notation; (*b*) *Aural*—volume of tone mistaken for depth, brightness for height.

Illustrated by voices, instruments and diagrams.

MARCH 1.—"The British Art Section of the St Louis Exhibition." By ISIDORE SPIELMANN, F.S.A. SIR EDWARD POYNTER, Bart., P.R.A., will preside.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

FEBRUARY 16.—"The Indian Census of 1901." By SIR CHARLES A. ELLIOTT, K.C.S.I., LL.B. The RIGHT HON. LORD GEORGE HAMILTON, G.C.S.I., M.P., will preside.

MARCH 16.—"Manipur and its Tribes." By T. C. HODSON (late I.C.S.).

APRIL 6.—"The Prospects of the Shan States." By SIR J. GEORGE SCOTT, K.C.I.E. ("Shway Yoe"), Superintendent and Political Officer, Southern Shan States.

MAY 11.—"The Manufactures of Greater Britain. —III. India." By HENRY JOHN TOZER, M.A.

COLONIAL SECTION.

Tuesday afternoons at 4.30 o'clock:—

FEBRUARY 28.—"The Manufactures of Greater Britain.—I. Canada." By C. F. JUST, Canadian Government Service in London.

MARCH 28.—The Manufactures of Greater Britain. —II. Australasia." By the HON. WALTER HARTWELL JAMES, K.C., Agent-General for and late Premier of Western Australia.

MAY 23.—"The Cape to Cairo Railway." By SIR CHARLES H. T. METCALFE, Bart., M.Inst.C.E.

APPLIED ART SECTION.

Tuesdays, at 4.30 or 8 o'clock:—

FEBRUARY 21, 8 p.m.—"The Queen Victoria Memorial as compared with other Royal Memorials." By MARION H. SPIELMANN, F.S.A. JOHN BELCHER, A.R.A., President of the Royal Institute of British Architects, will preside.

MARCH 21, 8 p.m.—"West Country Screens and Rood Lofts." By F. BLIGH BOND, F.R.I.B.A. G. F. BODLEY, R.A., will preside.

APRIL 11, 4.30 p.m.—"The Monumental Treatment of Bronze." By J. STARKIE GARDNER. SIR GEORGE BIRDWOOD, K.C.I.E., C.S.I., will preside.

CANTOR LECTURES.

Monday evenings, at 8 o'clock:—

DUGALD CLERK, M.Inst.C.E., "Internal Combustion Engines." Four Lectures.

LECTURE I.—FEBRUARY 13.—*Fundamental Principles.* — Internal combustion engines essentially air engines—Thermodynamics of air engines—Two

types, constant volume and constant pressure—Theory of compression—Efficiencies without heat or other losses—Gaseous explosions—Temperature measurements—Bunsen's method—Efficiencies with heat and other losses—Coal gas, petrol, alcohol and producer gas explosions: their differences and similarities.—Data still required.

LECTURE II.—FEBRUARY 20.—*Indicator Diagrams and Power Tests*—Diagrams from engines using coal gas, producer gas, blast furnace gas, petrol and heavy oils—Practical efficiencies and limitations in large and small motors for constant volume and constant pressure engines—Brake tests—Irregularities in diagrams, pre-ignitions, back ignitions, exhaust explosions, missed ignitions.

LECTURE III.—FEBRUARY 27.—*Examples of Internal Combustion Engines in Britain.*—Coal gas and producer gas engines, Crossley, National, Stockport—Blast furnace gas engines, Cockerill, Oechelhauser, Koerting, Crossley, National—Petrol engines, Wolsley, Liddeley, Daimler—Heavy oil engines, Deisel, Hornsby, National, Crossley.

LECTURE IV.—MARCH 6.—*Future Developments*—Suction producers—Blast furnace gas—Producer gas in power-stations—Marine gas and oil engines—Line of advance.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, FEB. 13...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Mr. Dugald Clerk, "Internal Combustion Engines." (Lecture I.)

Optical, 20, Hanove-square, W., 8 p m. Mr. L. W. Phillips, "Measurement of Absorption in Tinted Glasses."

Surveyors, 12, Great George-street, S.W., 8 p.m. Discussion on the papers by Mr. A. R. Stenning and Mr. William Menzies. "Urban and Rural By-laws and suggested Amendments," and "Building By-laws in Rural Districts."

Geographical, University of London, Burlington-gardens, W., 8½ p.m.

Mechanical Engineers, Storey's gate, Westminster, S.W., 8 p.m. (Graduates Lecture) Dr. J. T. Nicolson, "Results of Force Measurements with Cutting Tools, and their Application to Lathe Design."

Camera Club, Charing-cross-road, W.C., 8½ p.m.

Medical, 11, Chandos-street, W., 8½ p.m.

London Institution, Finsbury-circus, E.C., 5 p m. Prof. W. E. Ayrton, "Energy: American, British and Japanese."

TUESDAY, FEB. 14...Asiatic, 22, Albemarle-street, W., 3 p m.

Royal Institution, Albemarle-street, W., 5 p.m. Prof. L. C. Miall, "The Structure and Life of Animals." (Lecture IV.)

Medical and Chirurgical, 20, Hanover-square, W., 8½ p.m.

Civil Engineers, 25, Great George-street, S.W., 8 p.m. 1. Mr. Crosbie Trench, "Alfreton Second Tunnel." 2. Mr. Dugald McLellan, "The Reconstruction of Moncreiffe Tunnel."

Anthropological, 3, Hanover-square, W., 8½ p.m.

Colonial Inst., Whitehall-rooms, Whitehall-place, S.W., 8 p.m. Mr. P. A. Barnett, "Problems and Perils of Education in South Africa."

WEDNESDAY, FEB. 15...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Arthur Henry Anderson, "The Decline of the Country Town."

Meteorological, 70, Victoria street, S.W., 7½ p.m. 1. Mr. Edward Mawley, "Report on the Phenological Observations for 1904." 2. Mr. Hermann Elias and Mr. J. H. Field, "Observations made during a Balloon Ascent at Berlin, September 1, 1904." 3. Mr. J. R. Sutton, "The Winds of East London, Cape Colony."

Chemical, Burlington-house, W., 5½ p.m. 1. Mr. A. T. de Mouilpied, "The Condensation of Anilino Acetic Esters in Presence of Sodium Alcoholate." 2. Mr. F. D. Chattaway, "Nitrogen Halogen Derivatives of the Aliphatic Diamines."

Microscopical, 20, Hanover-square, W., 8 p.m. Mr. J. E. Stead, "Practical Micro-Metallography, with Experimental Demonstration."

Sanitary Engineers, 19, Bloomsbury-square, W.C., 7 p m. Mr. J. Thompson, "The Sanitation of Southend-on-Sea."

British Archæological Association, 32, Sackville-street, W., 8 p.m.

THURSDAY, FEB. 16...SOCIETY OF ARTS, John-street, Adelphi, W.C., 4½ p.m. (Indian Section.) Sir Charles A. Elliott, "The Indian Census of 1901."

Linnean, Burlington-house, W., 8 p.m. 1. Mr. J. G. Baker, "A Revised Classification of Roses." 2. Messrs. E. G. Baker, Spencer Moore, and Dr. A. B. Rendle, "The Botany of the Anglo-German Uganda Boundary Commission."

Royal Institution, Albemarle-street, W., 5 p.m. Prof. J. J. H. Teal, "Recent Work of the Geological Survey." (Lecture I.)

United Service Institution, Whitehall S.W., 3 pm.. Captain E. D. Swinton, "The Comfort of Troops on Active Service."

Historical. Clifford's-inn Hall, Fleet-street, E.C., 5 p.m. Annual Meeting.

Numismatic, 22, Albemarle-street, W., 7 p m.

Camera Club, Charing-cross-road, W.C, 8½ p.m.

Mining and Metallurgy. Geological Society's Rooms, Burlington-house, W., 8 p.m. 1. Mr. H. E. West, "Early Dry-Crushing Plants in Western Australia and the Introduction of the Filter Press." 2. Mr. Hugh F. Marriott, "Deep Borehole Surveying." 3. Messrs. A. Jarman and E. Le Gay Brereton, "Laboratory Experiments on the Use of Ammonia and its Compounds in Cyaniding Cupriferous Ores and Tailings."

FRIDAY, FEB 17...Royal Institution, Albemarle-street, W., 8 p.m. Weekly Meeting. 9 p m., Mr. John W. Gordon, "High Power Microscopy."

North-East Coast Institute of Engineers and Shipbuilders, Newcastle-on-Tyne, 7½ p.m.

Quekett Microscopical Club, 20, Hanover-square, W., 8 p.m. Annual Meeting.

Geological, Burlington-house, W., 3 p.m. Annual Meeting.

Mechanical Engineers, Storey's-gate, Westminster, S.W., 8 p.m. Prof. W. E. Lilly, "The Strength of Columns."

SATURDAY, FEB. 18...Royal Institution, Albemarle-street, W., 3 p.m. Sir Alexander Mackenzie, "The Bohemian School of Music." (Lecture III.)

Journal of the Society of Arts.

No. 2,726. VOL. LIII.

FRIDAY, FEBRUARY 17, 1905.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

NOTICES.

NEXT WEEK.

MONDAY, FEBRUARY 20, 8 p.m. (Cantor Lecture.) DUGALD CLERK, "Internal Combustion Engines." Lecture II.

TUESDAY, FEBRUARY 21, 8 p.m. (Applied Art Section.) MARION H. SPIELMANN, "The Queen Victoria Memorial as compared with other Royal Memorials Abroad."

WEDNESDAY, FEBRUARY 22, 8 p.m. (Ordinary Meeting.) JOHN E. BORLAND, "Some Misconceptions of Musical Pitch."

Further details of the Society's meetings will be found at the end of this number.

CANTOR LECTURES.

Mr. DUGALD CLERK, M.Inst.C.E., delivered, on Monday evening, 13th inst., the first lecture of his course on "Internal Combustion Engines."

The lectures will be published in the *Journal* during the summer recess.

INDIAN SECTION.

Thursday afternoon, February 16th; SIR STEUART COLVIN BAYLEY, K.C.S.I., C.I.E., in the chair.

The paper read was "The Indian Census of 1901," by SIR CHARLES A. ELLIOTT, K.C.S.I., LL.D.

The paper and report of the discussion will be published in a future number of the *Journal*.

PROCEEDINGS OF THE SOCIETY.

APPLIED ART SECTION.

Tuesday evening, January 31st; LEWIS FOREMAN DAY, F.S.A., Vice-President of the Society, in the chair.

The CHAIRMAN, in introducing the readers of the papers said that they were well known to the majority of those present, and those who did not know them probably knew indirectly some of their work. A few years ago it used to be a grievance amongst examiners at South Kensington and elsewhere, that students defaced their designs by very bad lettering. County Council and other schools since that time had taken up the teaching of calligraphy, and nowadays wherever there was an exhibition of arts and crafts one could be pretty sure of seeing good script, which was very largely the effect of the authors' teaching. Both Mr. Johnston and Mr. Hewitt were masters of their crafts, and he was sure their contributions would be most interesting.

The following two papers were read—

CALLIGRAPHY AND ILLUMINATION.*

BY EDWARD JOHNSTON.

THE DEVELOPMENT OF WRITING.

The development of the book-hands from the Roman alphabet, showing the growth of varied letter forms for useful or ornamental purposes, is the key to the practical study of calligraphy and illumination.

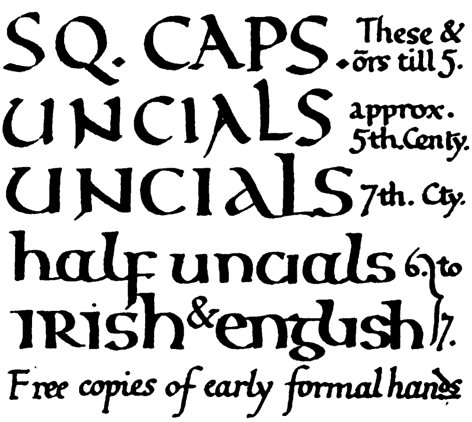
Doubtless the forms of the letters of the fine

* This paper forms a running commentary on 42 slides which were shown. I have to acknowledge the courtesy of Mr. John Hogg for permitting the use of these before their publication in book form. The seven rough diagrams here given have been since made specially to illustrate this paper.—E.J.

inscriptions in stone and the forms used in writing, acted and reacted upon each other, so that the pen, the chisel, and the brush all contributed to the development of the perfect forms of the Roman Capitals used in the beginning of the Christian era.

Formal writing may be said to begin with the "Square Capitals"; these and kindred forms were used till about the beginning of the fifth century. Though it had not yet become customary to separate the individual words, this writing—1,500 years old—is extremely legible; the vague popular accusation against the old "crabbedness and unreadableness" more truly applies to the hands of ourselves and our friends.

Fig. 1.



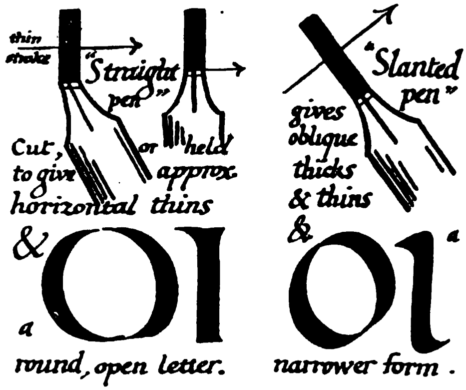
The beautifully rounded "Uncial" letter of the fifth century is a truer pen form. The "Half-" or "Semi-Uncial" writing of the sixth century is derived from mixed uncial and cursive forms.

The Cursive, or informal ordinary writing of the Roman capitals—with a stylus—produced the "Small Letters." These were adopted by the scribes and, after 200 years, were universally used for books.

The Roman missionaries brought the "Roman Half-Uncial" forms to Ireland, and the Irish missionaries brought their writing to England in the 7th century. The "Book of Kells" and the "Durham Book" are the marvellous works of the Irish and English penmen.

About this time the thin strokes of the letters became approximately horizontal, but a reveron to the earlier and easier method of holding the pen "slanted" led to the narrow and angular writing of the twelfth and succeeding centuries.

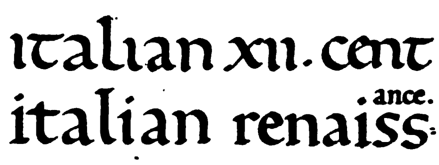
Fig. 2.



The "Caroline Hands" of the beginning of the ninth century—developed in France presumably under English influence—reformed the inferior Continental hands. Though written with a "slanted pen" it is very open and round.

In northern Europe in the course of time these fine qualities were lost and gave place to narrowness and angularity. In Italy, however, the twelfth century writing was exceedingly beautiful and round. And the Italian scribes of the Renaissance modelled their hands on such writing: the result is seen in a late fifteenth or early sixteenth century writing. The Italian printers following the scribes gave us the "Roman Small Letter" which is used to this day.

Fig. 3.



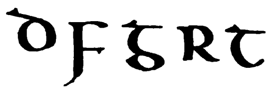
The evolution of our ordinary type letters and nearly all other important varieties—both useful and ornamental—is mainly due to the use of the pen.

Learning to Write.

In making practical use of the art of Calligraphy we may take as a model a good legible

round hand—such as the Anglo-Irish writing in the "Durham Book," and, after careful study, replace the archaic forms,* such as:

FIG. 4.



by later forms akin in feeling to the other letters.

This hand is written with a properly cut pen, which is used with the slightest possible pressure. The shape and the proportions of the pen nib, and the direction in which it moves, together produce the thins, thicks and gradated curves, and the graceful forms of proper penmanship. From such a round hand one would pass on to a more practical "slanted-pen" writing, and the accomplished penman develops naturally some sleight of hand and a characteristic manner, and so at length attains a fine, legible, and entirely personal handwriting.

An interesting proof of the power of the pen is given by taking the skeleton or "Essential Forms" of capitals and small letters—as we should make them with a pencil—and writing them with a "square cut" pen. The oblique letters (A, K, M, &c.) may be written with a "slanted pen," in order to lighten them; and the characteristic hooks, "heads" and serifs which the pen produces may be used to terminate the strokes.

The alphabet so written shows a remarkable degree of character and finish, produced entirely by the pen. A stronger and more practical form is produced by similarly using a "slanted pen."

Another kind of penmanship is seen in what we may call "semi-formal writing." This is written with a pen giving a somewhat stylographic form of letter, having no decided thicks and thins. This Italian sixteenth century example shows great rapidity, combined with beauty and legibility; it took the scribe but a little longer to write than we should take to scribble it, perhaps 10 to 15 minutes per page. The practice of such a writing might be of very practical benefit to many of us in reforming our ordinary hands.

* Unless we are writing in the Irish language which still retains these forms in the alphabet.—E.J.

ILLUMINATION.

Illumination has its beginning in the use of larger or coloured capitals to mark the commencement of books, chapters, verses and the like. Such letters are generally very different from "simple-written" forms, and may be described as "built-up" pen forms.

Great variety was introduced in the twelfth century "Versals;" and added flourishes, in another colour, were common in the thirteenth century. Line-finishings and flourishes on the ends and tails of letters accompanied the use of Versal capitals, and contributed to the growth of illumination. The decorated or decorative initial naturally became, and, I think, still remains, the central motive of the illuminator proper.

FIG. 5.

The true development of this art is most graphically sketched by Ruskin, in "Lectures on Art" (No. V.), where he says: "The pen . . . . is not only the great instrument for the finest sketching, but its right use is the foundation of the art of illumination . . . Perfect illumination is only writing made lovely; . . But to make writing itself beautiful—to make the sweep of the pen lovely—is the art of illumination." And also that, those who have acquired "a habit of deliberate, legible and lovely penmanship in their daily use of the pen . . . may next discipline their hands into the control of lines of any length, and finally, add the beauty of colour and form to the flowing of these perfect lines."

A very simple and delightful method of decorating a page of writing with pen-work is to take a few simple elements—a curve, a leaf, a circle, &c.—and build up a semi-organic pattern, as a bookbinder builds a pattern on a cover with a few stamps. The main stem springs from an initial and covers the ground with a few sweeping curves, the branches fill the corners and (built up) "flowers," &c., are placed in the larger spaces; evenly distributed leaves, stalks (drawn after the leaves), ten-

drils, &c., fill the interstices and produce a pleasant even covering. Black stems, gold leaves, and coloured flowers are used in a fifteenth century French illumination, made on these lines.

FIG. 6.

The finest and most interesting illumination, however, is that which may be produced by a good draughtsman. A more natural treatment of very delicate foliage, &c., is seen in an Italian fourteenth century MS. (in the British Museum: Addl. MS. 28841) of an unusual style.

For draughtsman - illuminators the plant forms in the old herbals, and Bewick's woodcuts are worth studying.

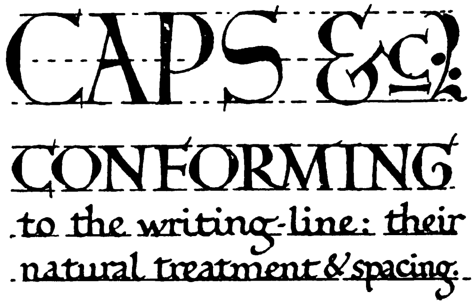
MAKING MS. BOOKS, &C.

To turn our work to practical account it is necessary to make definite things: the making of MS. books is the most instructive practice.

All good work more or less arranges itself; the size of the book (whether a folio, 4to., 8vo., &c.) may be determined by the size of the sheet of paper or skin in regular use. The margins are regularly proportioned for the comfort of the reader—wide enough but not too wide—and these partly determine the length of the writing line; for ease in reading and writing, the writing line should contain neither too few words nor too many—from four to eight words, or an average for ordinary use, of six words to the line, is suitable. This number of words means about 36 letter spaces, and so the size of the writing is determined by the number of words to the line. A reasonable distance between the writing lines determines the number of lines to the page (*i.e.*, in the space between the top and foot margins).

The writing lines are ruled throughout the book; on every page they form a proportional scale or "ready reckoner," to which the decorative capitals, &c., conform. The business part of the work—the writing—is completed, suitable spaces being left for decoration (capitals, &c.,) on the initial page and for chapter headings, &c.; the writing is then decorated.

FIG. 7.



While conforming to reasonable rules, we must preserve our freedom, one of the greatest virtues (and a more accurate naming of what is commonly admired as "spontaneity.") A text and its commentary (or other subordinate or explanatory text) may be made complimentary—a great convenience to the reader. Types of different sizes may be used in connection with illustrations, in order that the explanation may be on the same page with the picture.

CONCLUSION.

A fine title page by Holbein in a book printed at Basle shews a beautiful type—used throughout the book for headings—giving a much simpler and better effect than the majority of "specially designed" title pages.

A modern inscription in stone shows the possibilities of good lettering on foundation, memorial stones, &c.

A rather ornate treatment of a Communion service on vellum shews some ornamental possibilities of the work.

A perfectly plain brass shews some of the practical possibilities.

This paper can only briefly touch some of the divisions of a very large subject. Writing, illumination, and "lettering" offer a wide field for the ingenious and careful craftsman. The elements of the art are easily learnt by anyone, and it is easier than people suppose to make really beautiful things by taking a little pains. The practice of writing opens the way to a number of delightful occupations (to say the least), and compares in some degree with the practice of music. Above all, the educational value of penmanship is very great.

CALLIGRAPHY AND ILLUMINATION.

By Graily Hewitt.

"Illumination" is hampered by the narrowness of the conception of its scope. It has come to mean an extraneous prettiness added to writing, rather than the beautifying of writing itself; as we might fancy that by tying gay bows and ribbons to our chair legs or fireirons, and nailing up a rose here and there, we should be improving the appearance of our furniture. To be true decoration of lettering, illumination is a more serious affair, and concerns construction itself; and since the craft has lost continuity of tradition, and

Fig. 8.

suffered great degradation, any earnest practice of it needs much rudimentary knowledge of ways and means. The study of its tools and materials is no less necessary than the study of the models of past craftsmanship for help and inspiration; thus, a well-cut pen or chisel have things to teach we shall not learn from all the wonders in a museum. We can begin afresh through simple methods to attempt simple results, and come at the root of the matter. By illumination, therefore, I would understand, not the application of a dexterous scroll, or fifteenth or other century system of twiddle to a manuscript, but some wide generalisation to cover all the work of lettering, where, with dignity, discrimination, and thoroughness, the craftsman, whether with pen, brush, chisel, or printing-press, strives to give a material beauty to the words he has to present.

For illustration, I show on the screen a page, printed at the Ashendene Press, from the "Fioretti" of St. Francis. The simplicity, strength, and restraint in it are evident. Red is used in the marginal note, the initial letter and the chapter heading just above the A. The rest is black, and depends for effect upon careful selection of type, the massed evenness of its columns, its spacing, regular arrangement, and general tranquillity. But what is also notable is the inter-dependent ordering of all the means to the end, the book. The illustrator has not been content to make a picture only, but in making it has subordinated himself to this end, and employed the weight of line, the amount of detail, size and space, exactly suitable to the type he is to assist. And the beauty of the whole may be said to constitute true illumination.

Every such means, indeed, by which beauty may be given to words, are its concern: but only step by step. And we may begin to illuminate, in this sense, by making good letters on an appropriate surface with an appropriate tool. And beginning so we may expect to learn the better what beauty men have already given to them, and understand something of their possibilities and limitations, before we venture to apply any scheme of decoration of our own.

What, then, are *good* letters? And what style shall we affect? Have we the choice, any more than we have a practical choice in the matter of our clothes? And has this not been so in any century, save at epochs like the Renaissance? Our style stands evolved for us, and all there is for us to do is to make the best of it by honesty and refinement, at least until we have mastered it and have earned a right to improve upon it. And in this matter of lettering we are lucky; for our style, degraded enough may be, is after all founded upon the Italian scripts of the fifteenth century, and the magnificent early printing of the Venetians. We employ the same sort of Roman capitals, rounded small letters, and italics, or forms very closely allied. And as these meet our eyes in every newspaper we pick up we may wish them indeed better made, better spaced, better arranged; but we cannot make substitutes for them, even if we could devise better ones, without at once becoming less legible. For our eyes are accustomed to read them, and read them easily. And as

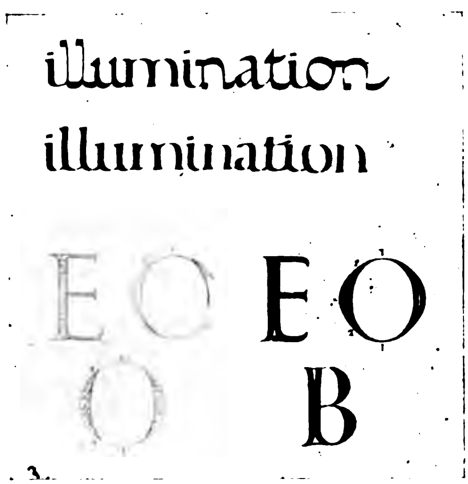
legibility is the first requisite of lettering (letters being primarily made to be read), we lay aside common-sense for the sake of artistic pride, if we attempt to create the unusual. It may be argued that, as we are the heirs of the ages, we may imitate with profit any and every example they have provided. The style we find existing, however, is surely the one *primâ facie* applicable to us; and to do otherwise than adopt it is to be re-making varieties human nature has either rejected or grown out of; and, moreover, to be foregoing the hope of proficiency with at least one of them, which continuous practice may give, while we stay to speculate and experiment with defensible alternatives. To compare great things with small, is not the charge brought against architecture that at the present day it has no style because it has so many?

How then may these Roman letters, large and small, be made as well as possible? The pen, by long and wide-spread usage, is recognisable as chief of the letter-making and modifying tools. An examination of its method, therefore, cannot but be of service, even for other or derivative methods, that their differences and the effect of these upon the letters may be appreciated.

The best aids to legibility are simplicity of form and regularity of construction. And to these elements refinement has usually added the beauty of contrast. Whether the pen's natural aptitude to make thick down strokes and thin side strokes, or our no less natural approval of thick stems and thin branches, is responsible for this is not the craftsman's concern so much as the observance of the feature, and with a nice regard for the regularity of its construction. We should at once resent as ridiculous an alphabet which proceeded as the upper one on the screen (Fig. 9) in disregard of this stem and branch feature, using contrast indeed but with no apparent regularity. It is distracting. We need to have the similar parts of the different letters made in a similar way, that their uniformity may give us peace. In the lower line such uniformity is observed. The principle is obvious enough in this instance; and yet a feeble method of making letters, especially the capitals, is responsible for its continual violation. And if the irregularity be but slight we are often at a loss to know why we do not like an alphabet, when we look at it and know we do not. It is safe to say that in this matter regularity is uniformity, and never monotony.

On the screen we have two methods of making Roman capitals. (Fig. 9.) That on the left may be called the crowquill-and-fill-in method, that on the right, the broad-pen method. In the former, the outline of the letters is drawn, and the inclosure inked in, and by it a strain is immediately put upon the drawer to measure his breadths evenly, as the pen does not help him to do this; and not only the breadths of his broad stems, but the breadths of their narrower branches. To keep these breadths even throughout the work is difficult, but if the letters are to be regular these breadths must all be similar. Besides this, the method tends to drawing by aid of a ruler, and to scamping the delicate concavity the outline of the stems should have in Roman capitals. The method's defect is more striking in the O's. For here again with no help from the pen the writer must make the gradation from extreme thickness to extreme thinness evenly four times, and, whenever a curve occurs in the work, must make that curve evenly gradated, and precisely equal to the other similar curves. He naturally flies to compasses to give him at least a circle. Yet the mathematical exactitude of a circle is perhaps undesirable for a Roman O, and if he thinks this, he must add a gradated bulge on

FIG. 9.



the outside as well as manipulate the interior increase. The strain of measuring as well as drawing results in a mechanical stiffness and wiriness, or else in irregularity and feebleness.

But if the broad-pen method is used, the tool is admitted to save all this trouble of measurement. Perhaps I need hardly point out how the stems are so measured, and the

branches also in the angular letters. Two strokes make the stem, one the branch; and, if you draw aright, the correct measurements follow equally throughout the work. It is surely as easy to draw a thick line as a thin one. In fact, it is easier; you can see better what you are doing. The disadvantage is that you cannot rub it out so easily if it goes wrong. Yet this hardly applies to work for process production, for there we can mend our mistakes pretty freely.

In the curves the advantage of the method is still more conspicuous, for, as you see, from 1 to 2 of the O, the single pen-stroke drawn aright does all the most delicate portion of the gradation from thick to thin for you, and will do this equally in every similar case. And beyond the directness and facility which the method is calculated to give with practice, that indefinitely pleasant and vigorous effect will be found passing into the work, which a convenient tool, allowed its part therein, never fails to bestow.

Another weakness in our construction of letters arises from an uncertainty we have as to their solidity. Have letters two or three dimensions?

In the early days of the Roman alphabet, letters seem to have been mere marks on a surface, with pen on papyrus or parchment, with stilus on wax, with chisel on stone. For at first chisel-cutting is no more than glorified stone-scratching. And possible solidity was not considered. Not until letters had been cut from metal and affixed to a surface do we get the notion of *literæ prominentes*, which were the forerunners of the luxurious raised inscriptions of mediæval times, and find their degraded progeny in Robinson's shop facia, where each distorted letter has a painted imitation thickness and casts an imitation shadow of an independent splendour, and all in fiercely isometric perspective to make it even more distracting. Would it not be well to free our practice of this attribution of solidity to letters where it does not exist, and to ascertain some rules for its wholesome construction in places where it may, to avoid such vulgar pitfalls?

Even in wood and stone this construction is indirect and uneconomical. For you must cut away the surface of your panel or block instead of cutting your letters, and, if you do not care to trust to luck merely, you have to consider the problem how high the letters should be raised, that in the position they are to occupy the light falling upon them may by the shadows cast assist, and not obscure them.

The very magnificence of the method, where magnificence is fitting, should warn us against its cheap and reckless application to the commonplace. And if Robinson argues that he is not concerned with good letters, but with catching customers' eyes, he may be persuaded that his name can be made to "stand out" without dishonour to a single letter,—by contrast, by isolation, by study of margins and arrangement generally.

For the arrangement of lettering with regard to its surroundings and its components is of as great importance, in its illumination, as the lettering itself. And the rules and conventions relative to the matter are natural and ascertainable. There is no artistic profundity or trade secrecy in the reasons, which forbid us to run our lettering all across an open book instead of setting it in two pages, for instance; which advise that these two pages be considered as two halves of a whole, the opening of the book, instead of as separate entities, that they may balance and help each other to present it evenly and agreeably before us, with due marginal isolation from all that may disturb our reading; which regulate the spacing out of letters and words that they may be read without hesitation; which tell us that the beginning of books, of chapters, even of paragraphs, may be pleasantly notified to us by the accentuation of larger or distinguished letters; and so on. All of which matters are the province and care of illumination, to be thorough.

But, suppose all these things duly settled to our minds with regard to an imaginary book, how may we further enhance its beauty? The simplest means of doing so are by gold and colour. Our distinguished letters may be gilded, or parts of our text which seem to claim an isolation or a prominence may be rubricated, these additions being, of course, made with no change of form or position in the lettering itself. The beauty of a mass of vermilion among the black, or of a ribbon of blue and red in a title or chapter heading, or down the capitals of the lines of poetry, is alone splendidly ornamental. The danger lies in a natural endeavour to glorify particular words rather than the page in which they occur; so that I have seen sacred writing disfigured, instead of aided, by the reverence which has set the G of God in colour through it, and, by not considering beforehand that colour mingled into black may become just rusty patchwork,

has entirely failed in the honour it hoped for.

Again, the initials and capitals may be not only coloured, but set in the margin instead of the text, hung out like flags from a wall; and this has the advantage that the ornamental effect of the unbroken page of black text is not lost sight of, as is apt to be the case where a piece is taken out of the corner or side of it to provide space for the gay letter.

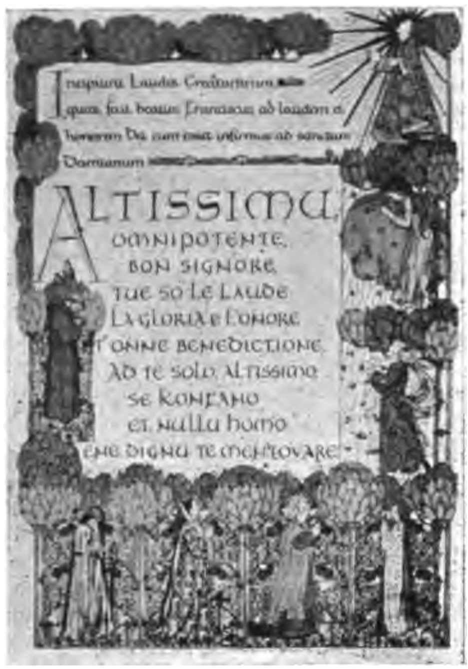
As to gold, there is no simple ornament to compare with it. Isolated or in masses, it is always splendid; and as long as the subject matter of the writing justifies so magnificent a dress, well formed letters gilded are never vulgar. But the gold must be gold, not shabby yellow; and unfortunately, with the loss of tradition, the craft has lost all confident technique in the matter. We have the old recipes for gesso and various new ones; we make our own and fail miserably; in desperation we buy preparations we know little about, and fail again. We have no certainty that our gold leaf will stick, will burnish, or in a year or two will not be a dull network of cracks. Yet until we can gild well again our illumination can never be great. For good gilding is the crown of it all. Several of us are trying to better the business, but until a sympathetic chemist brings us competent aid I do not imagine we shall progress much further than by finding out how many ways there are of not doing it.

From gold and colour our initial letters may advance yet further in decorative effect by at last giving forth buds; which buds may set out along the margin and develop into as masterful decoration as the craftsman is by this time capable of.

Here on the screen are some rough sketches of the way these letters began in the twelfth century to grow thus. And any decoration which proceeds from them so, can at least be confident that it is rooted aright with reference to its office, which is to ornament the text, springing from the place where the reason for ornament seems most naturally to arise—the initial letter. And in directing it, the plan to adopt seems most properly what I may call the *espalier* system, in which a gardener trains fruit trees. For so our growth can still be as naturalistic in detail as we may care to make it, and yet be bent to the necessities and conventional angularities of the body of text it adorns. To pretend that a flower or shrub will grow by right angles, or on the other hand to let it grow naturally in disregard of its office here, is to ignore its proprieties or our pages. The same system can be adopted where we plant its roots at the base of pages, as is conveniently done where the whole of the margins are to be filled.

As to materials, the work depending so much upon detail, and being intended to be looked right into, these should be always of the best. The parchment (for there is nothing better) should be of the finest consistent with due opaqueness. And here we are rather poorly served. Parchment is not what it was; and this seems as much the sheep's fault as

FIG. 10.



the manufacturers'. For modern farming has fattened them till they can no longer grow skins as fine and opaque as of old. And with all our french-chalking and pumice-stoning we cannot make them thin enough and pliable enough, or free them quite from grease.

Our ink must be fluid, yet quite black and glossy; our colours just as pure as possible. It is a continual astonishment that students should imagine pure colour can come out of a messy paint-box, or that the same pen, brush, and water can be used to apply them one after the other. We need so few colours that they can easily be kept entirely separate. Red, blue and green are enough; and pens are cheap. Turkey quills for stiffness, goose quills for

pliability, reed and cane pens for large work, should be kept in fair quantities, and, it is not superfluous to state, should be wiped when done with.

For gilding, the gold leaf should not be too thick. The thicker will not stick to the edges of the work, the thin sorts will not bear burnishing. A good thickness for most purposes is that of pure gold sold at about 3s. for 25 leaves.

Fig. 8 (p. 327) shows a specimen of the budded letter. An illustration of the *espalier* method spoken of for covering all the margins is seen in Fig. 10. Note how the stems ascend each side, and are trained to give off branches where required, and the trellis for the rose trees at the bottom. The sun, at the right hand top corner, is burnished gold. The photograph necessarily fails to give the lightness of the original. In particular the foliage, being covered over with gold line work to show the veins and stems of the leaves, is much gayer and brighter than the photograph suggests.

DISCUSSION.

Mr. HALSEY RICARDO thought that the interest in beautiful handwriting that had occasioned the two papers and the large audience to attend was satisfactory evidence of the growth of a general artistic feeling, concerned in seeing that the smaller details of life were made beautiful as well as the large. This represented a more healthy feeling and more capable of development than a taste for fine art complex with an indifference to the appearance of the smaller necessaries of life, which was the mark of an inartistic age. Good handwriting, being within the reach of everyone, was popular art, and to find a desire for such an ideal becoming general was a very hopeful sign. It was owing to the labours of the authors and their predecessors, such as Morris, Cobden-Sanderson, and Emery Walker, that a book, well printed in good type on good paper and well bound, could easily be bought, which was a pleasure to hold and read, and which, at the same time, fulfilled the commercial requirements of being within the reach of the most modest purse. There was still a considerable gap between the calligraphy which the authors of the papers had been illustrating and the cacography most generally current. Something of this was due to the instruments in common use, whereas the illustrations shown and described were generated from the goose quill — not a common implement to-day, and only in use amongst people who had the will as well as the leisure to sacrifice to the art of good handwriting. He thought that the modern scribe might do something—by inventing pleasant and intelligent contractions—towards helping the writer who is in a hurry. People nowaday sent each other short communications, as breathless as telegrams, which were scarcely decipherable by reason of the contractions as well as the unfinished forms of the letters. Another thing which he expected to see come within the illuminator's province, and more especially within the province of the scribes, was the writing of shorthand. Even in the way now used, with a pencil point and with no variety in the thickness of the strokes, a decorative page was obtained; but if some contrast in the density of the lines could be given, the writing might then compare with the Persian and Oriental inscriptions which made such a splendid decoration to their buildings. Lettering was a most effective form of wall decoration, and he would like to see large masses of it displayed on the walls of churches and public buildings, as well as private. With the use of shorthand, as well as lettering at full length, a great deal of useful and appropriate information could be presented on what are now blank spaces, and the buildings enriched in this way would gain in usefulness as well as beauty.

Mr. T. J. COBDEN-SANDERSON thanked the authors for their presentment of a most beautiful subject, both in its detail and in its general conception. In the first place, he wished to allude to what he might call the ideal types of which Mr. Johnston spoke at the outset, and the ways, materials and methods that had conspired to the introduction of an ideal alphabet. It must be borne in mind that alphabets were suitable to the material by means of which they were to be presented, and that there was hardly one only type in existence. They might abstract from the details of types which had been presented in the photographs, but obviously the stone-chiselled type was necessitated by the material, and by the instrument that was used in its formation. Another ideal form, the rounded form, was generated by the pen, which swept over the surface in a way that the graver could not do, and that gave rise to another type. Again, the material, even when a pen was being used, determined the type. Papyrus, being a fragile material, necessitated careful hand-writing, thin in its lines; and it was really only when vellum came into use much later that the glorious forms of calligraphy came into existence. The writer then felt, like a skater on firm ice, that he was on sure ground, and could give scope to his penmanship; he could press upon the surface and produce a broad line. Hence came the bolder alphabet, which had been illustrated by the authors. Then in later days, towards the tenth and twelfth centuries, paper and cotton were introduced, and, later still, almost too late for calligraphy, linen paper, which gave rise again to another type of writing. They had to bear in mind, in fashioning the writing of the present day, the material and instrument which were used, and must not affect an alphabet which was suitable for other circumstances. Passing on to the development of letters, many causes had been at work

in forming the alphabet. In the first place, there was the material, then the instrument and other influences which were more pertinent to the writer, such as haste and carelessness, both of which had been greatly operative in changing the characters of the alphabet. Again, convenience of space and a desire to compress much upon one page had changed the form of letter from the round form, with its broad and expanded letters, to a compressed; and there was a marked change in the early centuries from the round alphabet to the oval alphabet, in which there was height and very little breadth. Afterwards there came a reform, and the rounded form was reproduced. Associated with the craft and its materials were many delightful memories alike of lands and people. For instance, papyrus took one to Egypt, where they had obtained the beginning of the alphabet in use to-day. Vellum was chiefly associated with the rather decadent and yet noble city of Pergamos, where it was supposed not indeed, to have been invented or brought into use, but to have been more beautifully prepared. Then there were recollections of Italy and the blue Mediterranean; and later, when they came to the Christian times, monks and monasteries and their wanderings; how they went through France to Ireland and the north of England, Scotland, and Northumbria, and south again to France. It was no small craft that the authors had described; it was a world-wide vision which it was a pleasure to hand over to future generations. He rejoiced that the work was growing up again: under the authors' care it was in safe hands, and he trusted that the pupils who grew up under their influence would make the world, in that respect, more beautiful than it was at present. He hoped that the spirit of it would take possession of society as a whole, and instead of the people living a life of national strife and excitement, they would take themselves to more peaceable and beautiful pursuits.

Mr. W. Coldstream thought the subject of the papers was one of world-wide interest. As one who had lived most of his life in the East, he ventured to think that the calligraphy of some of the Oriental nations was well worth the attention of those who devoted themselves to the study of the art. The old manuscripts of Persia and India, such as MS. copies of the Quran in Arabic, the Shah Namah and Gulistan in Persian, and of some of the Hindi and Sanskrit works were often beautiful and very valuable examples of decorative writing. There was a great variety of form in the characters, and some of them were of considerable artistic value. Probably most present were familiar with the Arabic and the cursive Persian characters, but even the massive characters of the Hindi and Sanskrit, and the circular characters of some of the South Indian languages, were not without decorative effect. He often thought a little more might be done with regard to decoration by lettering in this and other European countries. It was well known that the Mahommedans had a religious objection to introducing any copy of living forms, either in sculpture or painting, and in order to make up for that loss of decorative material, the Mahommedans of Persia, Arabia, and India had devoted great attention to the development of various forms of Arabic and Persian writing, to the artistic evolution of forms of letters, and the cultivation of decorative styles, some of which were striking and effective. The Alhambra and other Mahommedan buildings in Spain were well known as beautiful examples of Saracenic architecture; and the façades, arches, and columns of those buildings were often decorated in an effective and artistic manner by the various forms of Arabic writing. The different forms of Arabic writing were distinguished by separate names, such as the Toghra, the Nastalik, and so on, names familiar to Arabic and Persian scholars. He was in entire accord with Messrs. Ricardo and Cobden-Sanderson's suggestion that a good deal more should be done in the way of decorative writing on public buildings. The nation lost a good deal by not writing up, in more or less decorative forms, facts, figures, and inscriptions of eulogy or gratitude on such buildings, a practice which if adopted would add a very valuable and interesting feature to many of them. Further, he thought the familiarising the London public with the script of the various languages spoken in different parts of the British Empire was a question of almost imperial significance. When one considered how world-wide were the dominions of Great Britain, how many peoples and tongues were the subjects of the King, he thought something more might be done in the metropolis of the Empire to familiarise the citizens with the forms of the different characters and scripts which were used by the inhabitants of the various countries over which the King-Emperor ruled. That would be consistent with Imperial policy and carry with it distinct public advantages; because it was natural that when far distant citizens from the remote ends of the Empire came to its centre, their hearts would be rejoiced, and the feeling of common citizenship would be aroused and increased, when they saw sculptured upon columns, arches, and panels on great buildings in London the familiar characters of their mother tongues.

The Chairman said the authors had given not only a dissertation upon writing and the way it was done, but a sort of paean in praise of the pen. It was delightful to hear people speak so enthusiastically of their craft. As scribes and penman the authors had naturally confined themselves almost entirely to the use of the pen. He would like to say something about calligraphy from another point of view. Mention had been made of incising stone carving, which gave the real Roman lettering, where Roman lettering was at its best, and Mr. Johnston showed a slide which he thought compared very favourably with pen work. On the other hand, Mr. Hewitt spoke of it almost sarcastically as glorified scratching. Then, glorified scratching was something very fine.

Mr. HEWITT said he did not mean to convey that it signified a difference in depth; it was only a way of marking the surface.

The CHAIRMAN went on to say that the brush was a writing tool, and it was not, like the stylus and some other tools, a thing altogether of the past. Some of the papyrus writing was done with the brush; but as far as current writing was concerned, although the brush existed still in the East, it was a thing of the past in the West. But that did not apply to decorative writing. There was still a great number of people, lithographers, for example, who preferred the brush to the pen, and who did with it some very remarkable writing, which an ordinary observer would not be able to distinguish from pen work, although it would be plain to a brushman or a penman how it was done. The authors had not said a word too much about the charm, beauty, and fascination of penmanship, and especially about the directness of the pen stroke, which deserved to be insisted upon. But it remained for someone like himself, who was not *par excellence* an expert with the pen, to mention that there were other ways of writing. Granting the pen to be the best of all tools, it was not the only one, and even if it was the best it was not necessarily the best for everyone. In all work into which art entered at all, the question of personality entered, and if someone preferred to write with a brush instead of a pen why should not he? Why should he not use it for Italic as well as for Arabic writing? He insisted on this because he felt very strongly that every decorative artist ought to be master of one kind of writing, at all events, which he could put into his work; and if that was so, surely he had a right to choose the tool he liked, and to work with it. Illumination included both pen and brush work. Personally he preferred the pen or the brush by itself, a remark which probably would not be supported by many present. One enjoyed the beauty, charm and sentiment of the old missals; but that was because one was prepared to take the goods the gods provided, and not quibble with them; it did not seem to him quite the right thing nowadays. He was inclined to think that if there was to be painted illumination in a manuscript it would be just as well to write with brush also. Mr. Hewitt said that illumination was only a kind of carrying further of beautiful writing. He entirely agreed with that view, but in that case there would be all the more reason why it should be done with the instrument employed by the writer. That was a personal opinion, and he knew it was a heresy, but he would like to know what the authors thought on the point. At any rate, he could not see logically how illumination of a manuscript by a brush could be allowable and not also writing done with a brush. There was one place where a brush was preferable, in fact, almost necessary, *i.e.*, where the scale of the writing was so big that a pen would not do it and a brush would; brushes were of all sorts of sizes; and the manipulation of a brush came easier to many who had not facility with the pen. It was quite certain there was many a decorative artist, not a penman, who could put admirable writing into his designs with a brush which he could not do with a pen, even if pen work, however well he did it, would go generally with his design. With regard to the question of gold and colour in illumination, the effect of gold was most sumptuous, there was nothing to compare with it; but partly for that reason it seemed to him there were very few occasions when it could be used. Another heresy of his was not quite to like raised gold. Anything which destroyed the flatness of the book seemed to him wrong in principle, He knew that dugesso made the gold glitter, but it looked like a remnant of barbaric ages. With regard to colour, he would like to ask Mr. Hewitt whether he quite understood him that they should confine themselves to three or four colours. He did not see the reason for that, nor did he understand why the pigments should be used quite pure just as they came from the colourman, nor why they should not be mixed together, and why a separate brush should be kept for each. He also did not see why they should, as people mostly did nowadays in illumination, base themselves entirely on the mediæval illuminations. They should be studied by all means for what they could teach, but once learnt he did not see why they should be followed. Morris certainly did not do this, and he excelled both in penmanship and illumination, and was an ardent mediævalist. Morris departed very widely from tradition both in the design and in the execution of his illuminations; in colouring he did not use the primary colours of the old illuminators. The general effect of his illuminations was that they were rather green in tone than red and blue; he did not remember much gold in Morris's work, but he might have forgotten. With regard to drawing in illumination, he sketched in his ornament, his foliage and so on quite freely, not at all like the mediæval work; in fact it looked to him very often as if he had sketched in his leaves with the brush in colour, and put the outline in afterwards, whereas the mediæval method was always to draw the outline and fill in the colour. Apropos of that Mr. Johnston had shown how to set out an ornament springing from a letter, and had said that the line should be set out first, and the leaves then sketched in, making them grow afterwards. That was quite right, but he did not like the idea of drawing stalks from the leaves to the stem. He thought it was quite right to put in the leaves first, but then he should make the stalk grow from the stem to the leaf; the draughtsmen would get more growth that way. Both he and Mr. Johnston meant exactly the same thing, and only expressed it in a rather different way; but he thought Mr. Johnston's

statement might mislead some of the students present. Apropos of a slide shown, Mr. Johnston had said something which he thought might be misinterpreted with regard to doing the thing quickly. All the disposition of the design ought to be considered carefully before the illuminator put in detail, and then it could be done as "slickly" as he pleased. But anything would not do; it all wanted great consideration. Everybody present must agree about the necessity of legibility of writing. The need was for plain writing, and it was in plain writing unadorned with flourishes that the penman showed what he could do. Even the beautiful uncial writing which had been shown was hardly familiar enough to many people quite to go down with them. But there was a use for lettering of a more ornamental kind than that which had chiefly been referred to. Attention had been called to the beautiful Arabic writing, but the Arabs were allowed very much greater freedom with their lettering than the British philistine would allow present day artists. He wanted everything terribly plain. Lettering ought to be introduced a good deal more into decoration than it was, but it could not be done until people allowed them a little more liberty. He was not arguing against anything that had been said, but simply wished to point out that there was a form of calligraphy on which it remained for somebody else to speak, and he was hoping that what he had said on the subject would draw the authors to say something more. Mr. Ricardo had referred to penmanship, and the authors had insisted upon the quill. He admitted that it was a beautiful and a sympathetic instrument to write with, but there was at least one objection to it, namely, that the cutting of a quill was an art in itself, and one in connection with which the artist was apt to be impatient. It was not altogether unreasonable for a man to prefer an instrument which would not fail him at a critical moment, which he could rely upon, and which would last, not for a line or two, but for the writing of a volume if need be. This was an age of steel pens, gold pens, and fountain pens. There was an advantage in having a pen which was not one minute overflowing and the next minute dry; the fountain pen had been a boon and a blessing to men. The misfortune was it spoiled them for other pens. The nib in common use was not made for calligraphy, but there seemed to be no reason why, if scribes insisted upon having their pens made in a particular way, they should not be of the right "cut," and even if they fell short of some of the qualities of a quill they would have qualities of their own which made up for that. It was not to be supposed that manufacturers would readily, if ever, be able to supply them with a nib which would satisfy enthusiasts of the quill, but he thought such a pen as he had suggested would tempt people to write beautifully where now the quill deterred them. We lived, after all, in the twentieth century. In conclusion, he proposed a very cordial vote of thanks to Messrs. Johnston and Hewitt for their valuable papers.

The resolution of thanks was put, and carried unanimously.

Mr. JOHNSTON, in reply, said that he was in almost entire agreement with the supplement to Mr. Hewitt's and his own paper which the various speakers had given. The whole subject was really a question of time. Being compelled by the shortness of time to give merely the "headings" of a very large subject, he spoke of what he knew best, and, as he did not know much about stone work, brush work, and the like, he did not refer to them. Two or three speakers had referred to the quill. The great virtue of the quill pen was that it could be cut to suit one's hand, and, as everybody knew, no two hands were just alike. Most truly was it an art to cut a quill pen, but once it was cut it would make the letters for the writer, who had no further trouble. With regard to the use of a metal pen, it was just possible that a steel pen might be made, but steel pens had not that beautiful feeling and elasticity. The great difficulty would be to get the requisite slant and shape of the nib, and probably one writer would find he was always digging the pen into the paper, and another would find he could make only part of the nib touch. It was always possible to fit the quill to one's hand and the work required to be done. Something might be done with a gold pen, in fact, he had actually tried a gold fountain pen, sacrificing half a guinea to the experiment. He found that he could write four times as much without sharpening the nib, but that it took him half-an-hour to sharpen the nib when it got blunt. He went to the Swan Fountain Pen Company, who said they would make a nib for him, only it would have to be made in New York, and he would have to pay 9s. for each nib, and he must take a dozen of them, and it would take four months to get them over, so he went back to the humble quill. Perhaps it was hardly right for a mere penman to speak on the question of contractions. Contractions were certainly most useful in mediæval times, and he only wished they could be used now. But he did not think penmen would start the innovation; perhaps the Society of Arts might use its influence in that direction. Mr. Sanderson had referred to the various forms of letters, and stated that there was no specially perfect one, but that each was fitted to its use. Of course he was quite unable to refer to the innumerable perfect forms of letters which had been used; he only referred to the kind which he had been constantly working on himself. Most certainly the material, the instrument, the haste, even the carelessness of the early Roman scribblers on wax tablets, and various other things all contributed to various perfect forms. He did not claim for a moment that the pen gave them everything, but the pen was the one great instrument from which they could get something really definite; it would not let one go wrong, and therein lay its great

educational value. Again, everybody could use pen, ink and paper. Very few people at the present day who lived, say, in a modern flat, could bring in a tombstone and chisels and practice cutting letters in that way; but he thought much could be done by casting little plaster of Paris slabs, and, before the plaster had got so hard that it would chip, cutting inscriptions on them. Some very beautiful work might be turned out in that way; but that would not be strictly practising the chisel form of letter, which required a chisel and mallet and real, practical slab of stone. Oriental calligraphy was exceedingly beautiful, but it was hardly practical enough for modern requirements, considering the terrific haste with which all subjects had to be attacked. Its value might be regarded as more ornamental than useful. Moreover, it did not agree with the Roman letters, which must be adhered to in some shape or other. The Chairman had said something about carefully debating how forms should be written and then working as "slickly" as possible. He entirely agreed with those remarks, but he thought that the early illuminators did not do much as a rule of that careful debating, because they had tradition at their backs, whereas artists at the present day, not having tradition, must naturally proceed with more care, not to say anxiety. He felt most strongly that while they might give all the care and almost painful debating to how work should be performed, especially when it was really great and important work, when it actually came to the doing of the work the quicker it was done the better. As a general rule, the quicker the writing the better; the more direct the work the more absolutely natural and free from artificiality. He very much objected to the habit possessed by a great many students of under-laying their work with a substratum of sketching in pencil. All that debating should be done aside. The student should have made up his mind and screwed up his courage to the sticking place, and *then* get the work done as quickly as he could. It would be a very great pleasure to him if the Society of Arts would allow him, once a week, to tell such an audience a little about what interested him in the kind of work under discussion, but he had only been able to summarise a few points of interest. All that he had said—and he believed that he could also speak for Mr. Hewitt—had to be taken in the sense that *there was a regular way of dealing with regular occasions, and a special treatment had to be adopted on special occasions*, therefore, when it might be thought that they were rather too restrained and had held back from one possibility and another, they only meant that, in the ordinary way, with a view to ordinary legibility, such and such proceedings would be adopted; but, on special occasions, there was no liberty which he would deny the scribe or letter maker.

Mr. HEWITT, in reply, said that the Chairman was an advocate of not mixing the methods of pen and brush work. He humbly agreed with Mr. Day up to almost the end of his remarks, because he thought that if in the process of an illumination one came to a point at which one wanted to spread colour over a surface, it was uneconomical, indirect and inadvisable to use the pen instead of spreading the surface at once with colour from a brush. The remark not only applied to laying in a broad background, but even putting in colour on a large leaf. Apart from that, he thought one was much better advised to keep to one tool; and the students in the classes did confine themselves to one tool, the pen. In the slides shown all the letters were pen letters, with the exception of the final slide, the illuminated part of which was done with a brush. He hoped, therefore, that he would not be accused of mixing up their methods.

The CHAIRMAN asked if Mr. Hewitt would have had any objection to the lettering in the last slide shown being done with a brush if the artist had been so disposed.

Mr. HEWITT replied in the affirmative, for the reason that the brush was such a very awkward instrument. The pen, on the other hand, was a firm instrument, which measured its own pressure. The writer only touched the paper with his pen, and it would keep the same spread of point, and so give a broad downward stroke with equal thickness without any effort. But a brush was very elastic, and was inclined to spread, so that as a line was drawn down it would spread out according to the pressure applied.

The CHAIRMAN remarked that anyone who was facile with the brush could draw a line as straight as if he were using a ruler.

Mr. HEWITT replied that all his remarks naturally referred to the student and the beginner. He particularly emphasised that in his recommendations as to the purity of colour. He almost thought for a moment that the Chairman could never have seen a student working with water, in which flowers had been kept for a week, with a brush which had been used for indigo, and a pen which had ink in it, trying to rubricate with pure vermilion. He only intended to advocate intense care with all materials.

Mr. CHARLES T. JACOBI (of the Chiswick Press) writes:—The two papers read on February 2nd last by Mr. Johnston and Mr. Graily Hewitt respectively on "Calligraphy and Illumination" were admirable in each case, and I was much interested in the slides shown, some of which were I confess a revelation—especially some of those diagrams tracing the evolution of the various forms of letters, as also were the drawings of the different pens and tools used by the modern exponents of what may be considered almost lost arts. I was sorry that I had to leave early and thus missed the opportunity of hearing the discussion

bearing on these two important and relative subjects. As a typographer I acknowledge that the more I see of the old forms of the alphabets the more I am convinced that if the creators of our modern founts of type were to make a greater study of these examples of letterings, and also if our present-day printers were more thoroughly to grasp the general principles which influenced the writing and planning out of the early manuscript books and the first printed volumes, we should I am sure more nearly approach what we might consider the ideal book, and at the same time we should be less inundated with specimens of what may be termed *l'art nouveau* in alphabets. In expressing such opinions I need only say that I am referring more particularly to those volumes which necessitate some amount of artistic treatment, but there is no real reason why the old traditions should not apply more or less to the ordinary run of book-printing, and I would yet go a step further and submit that such traditions should generally influence the whole art of printing. But, alas, commercial considerations prevail too much in this age of cheap literature, and it will require a very great effort to eliminate what is bad in type characters, and to restore those forms which may be considered as being more conventional in their construction.

TENTH ORDINARY MEETING.

Wednesday, February 15, 1905; ROBERT KAYE GRAY, M.Inst.E.E., Vice-President of the Society, in the chair.

The following candidates were proposed for election as members of the Society:—

Barratt, Reginald, A.R.W.S., Arts Club, 40, Dover-street, Piccadilly, W.
Beckett, Henry Barron, Mailla, The Green, Wimbledon.
Bertram, Henry, 1a, Cooks-road, Stratford, E.
Bonnett, Charles, Messrs. F. and C. Osler, Hornby-road, Bombay, India.
Brincker, John Augustus Herman, M.B., B.S., M.R.C.S., the Borough Hospital, Croydon,
Buck, Edward Clarke, Assistant City Engineer, Pretoria, Transvaal, South Africa.
Casey, Mark Patrick, Municipal Engineer, Lucknow, India.
Crosse, L. Arthur, J.P., R.M. Office, Nqutu, Zululand, Natal, South Africa.
Densham, Sidney Charles, 152, Adelaide-road, N.W.
Johnson, Charles Grove, F.R.I.B.A., Apartado 610, Mexico City, Mexico.
Lisbôa, Miguel Arrojado Ribeiro, M.Am.I.M.E., Rua Costa Gama, Villa Japurá, Petropolis, Rio de Janeiro, Brazil, South America.
Perry, George A., 13, Carlton-road, New Southgate, N.
Redwood, Iltyd I., Bantry-house, Belvedere, Kent.
Sparrow, Reginald George, Lenton-avenue, The Park, Nottingham.
Vidyasagar, Panjabbhudana Pandit Bulakirama Sastri, M.R.A.S., Mayo College, Ajmer, Rajputâna, India.

The following candidates were ballotted for and duly elected members of the Society:—

Ahrlé, F. H. C., 82, Cavendish-road, Harringay, N.
Basden, Rev. George Thomas, B.A., Church Missionary Society, Onitsha, Southern Nigeria, West Africa, and 112, Caversham-road, Reading, Berks.
Black, Captain John Cameron, A.M.I.N.A., The Scottish Shipmasters' and Officers' Association, 128, Hope-street, Glasgow.
Doe, Austin, 42, Claremont-road, Forest-gate, Essex.
Gyles, Nathan, 8, Young-street, Doncaster, Yorkshire.
Hasluck, Paul N., "Ebor," Redhill, Surrey.
Heath, Henry, 2, St. Swithin-street, Worcester.
Kelly, Major Arthur D. D., Weston, Duleek, Co. Meath, Ireland.
Leggatt, Mrs. E. O., 15, Savoy-court, Strand, W.C.
Macfadyen, John Beith, 65, Apollo-street, Bombay, India.
Mackenzie, Alexander, 19, Greenhill-gardens, Edinburgh.
Robertson, Duncan, Forres-park, Trinidad, West Indies.
Skinner, George, A.M.I.Mech.E., 19, Russell-street, Bolton.
Smith, Vincent, Sheffield-road, Chesterfield.

The paper read was—

THE DECLINE OF THE COUNTRY TOWN.

By ARTHUR HENRY ANDERSON.

There are probably few people possessing any extended acquaintance with the rural districts of England who cannot, from their own experience, bear witness to signs of decay in some one or more of the older and smaller towns of the country. Almost everyone must be familiar not only with single instances of declining towns, but also with the special causes to which decay may be attributable. But though it is true that in this limited fashion most people are acquainted with the spectacle, it is no less true that there is an almost total ignorance as to the real extent and gravity of

a melancholy feature of the modern shifting of population. It is a remarkable fact that in every county the smaller towns are declining—in numbers and to a degree quite surprising. What is equally remarkable, however, is that this important fact has not yet been realised by the country at large.

In saying this, I am not losing sight of the extraordinary amount of attention bestowed upon rural problems at the present time. It is, perhaps, only natural that the period following the publication of the census results should witness a revival of interest in all such matters, and the suggested alterations in our fiscal policy have only served to augment that interest. In every direction the problems suggested by "the rural exodus,"—the many questions of rural depopulation—are being discussed with an intensity and liveliness of conviction that indicate a general recognition of their importance. In political speeches, in reviews and leading articles, in newspaper correspondence, at meetings and conferences, the many aspects of this wide and vital question have been discussed by the expert and the layman. Though there may be wide diversities of opinion as to the significance of the facts, and as to the remedies proposed, there is no room for difference as to the facts themselves, that the depletion of the villages is a process that nothing seems able to arrest. In view of this widespread knowledge of the depopulation of agricultural districts it seems perhaps not a little surprising that concerning a subject closely related—though in many respects quite independent—the general public should be almost wholly ignorant.

The reason for this ignorance is to be found largely, I think, in the form of the census returns. In many respects the reports of the Registrar-General are of course beyond praise. They are admirable in their comprehensiveness. They supply, in a multiplicity of tables, a mass of detailed information of the highest value, but curiously enough there is one point of really national importance concerning which information is not tabulated or summarised. In the tables of population for urban and rural districts comparison with the previous enumeration is, of course, supplied, and the respective increase or decrease shown. In the tables of aggregates, however, the total decreases do not appear, and in the summaries affording comparison with the preceding census the net result of the variations is alone disclosed. For purposes of convenience, the towns are classified into groups according to their population. In each class the Census of 1901 shows an increase, varying from 23·15 per cent. in towns with a population of 50,000—100,000, to 4·6 per cent. in towns with a population of less than 3,000. But, as in these tables the increasing and decreasing towns are taken together, the resulting total increase is merely the balance of increases over decreases. It is obvious that the importance of the results must depend upon the respective proportions of increasing or diminishing units. This is exactly where the census returns fail to present the true state of affairs. Indeed, the tables serve to mask the real condition, which can only be ascertained at the cost of considerable trouble in analysis and collation. Turning aside for a moment from our main purpose, we can realise the extent to which this method of presentment obscures the facts by examination of the tables of population of the rural districts. Out of 666 districts, no less than 421 (or 63·21 per cent.) show a diminution as compared with 1891, yet the net result of the figures is an increase on the whole class of 2·9 per cent. The value of such an increase must of necessity be very materially affected according as it represents a fairly general rise of population throughout the whole area, or large increases in comparatively few districts outweighing decreases in many districts. As a matter of fact the latter is the case, though there is nothing in the summaries to suggest this, and it is only brought to light by a closer examination of the detailed tables. Thus one discovers—what is really the case—that rural districts bordering upon large towns are in the main increasing, while exclusively rural districts are declining. Though this does not affect our present enquiry as a fact, it illustrates the method by which certain aspects of the census figures are needlessly obscured.

Coming now particularly to the towns, the following tables will show how entirely the official presentment omits the point of importance to which I am drawing attention.

Table No. I. is the summary of the population of urban districts as given in the preliminary report.* Table II. supplies information which is, of course, obtained from the census returns, but which is nowhere therein presented in tabular form. In preparing this table I have

* The summarised figures throughout are taken from the preliminary report, where they are more conveniently grouped. Although the figures are liable to correction in the completed county returns, the alterations are infinitesimal and do not affect the result.

altered the division of the classes, showing separately the towns with populations between 5,000 and 10,000, and between 2,000 and 5,000. This sub-division seems to afford a fairer view of the matter, and as places with a population below 2,000 can hardly be considered as towns, they are left out of account.

TABLE I.

Urban Districts with population of :—	No. of Districts.	Aggregate Population.		Mean percentage of increase.
		1891.	1901.	
250,000 & upwds	9	7,293,005	7,972,790	9·32
100,000–250,000	24	2,987,836	3,517,912	17·74
50,000–100,000	42	2,448,704	3,015,571	23·15
20,000 – 50,000	141	3,683,501	4,433,823	20·37
10,000 – 20,000	219	2,538,281	3,006,280	18·44
3.000 – 10,000	472	2,396,204	2,693,230	12 40
Under 3,000	215	396,446	414,664	4 60

TABLE II.

Urban Districts with population of :—	No. of districts.	No of districts showing decreasing population.	Per cent. of decrease.	
			In Nos of districts	In population.
250,000 & upwds.	9	—	—	—
100,000–250,000	24	—	—	—
50,000–100,000	42	2	4·76	1·65
20,000 – 50,000	141	10	7·09	3 94
10,000 – 20,000	219	21	9·59	3·58
5,000 – 10,000	271	40	14·76	5·05
2,000 – 5,000	351	114	32·48	5·74

A comparison of these tables quickly brings to light important points of difference. The official table is, at first sight, a very encouraging document. In every class there is an increase—in all classes but one, a large increase. The natural assumption is that all is well with our towns; that there is a satisfactory general increase. How little this assumption would be justified is shown by the second table, which reveals the astonishing facts that:—Of towns with a population of 10,000–20,000, *one in ten is decreasing.* Of towns with a population of 5,000 - 10,000, *one in seven is decreasing.* Of towns with a population of 2,000 - 5,000, *one in three is decreasing*; and 187 towns with populations varying from 2,000 to more than 50,000, had declined in population in the decade ending 1901. The decrease in many cases is small, but in the aggregate it is a serious item. Its proportion can perhaps best be realised by calculating the effect upon the total population of a corresponding decrease all round. Instead of an increase in England and Wales of more than three and a-half millions, the Registrar-General would have had to report a decrease of one and a-half millions in the decade ending 1901.

It is clear, of course, that this represents at most but a shifting of the population. These figures demonstrate, however, that the smaller towns are now feeling, with the villages and hamlets, the terrible suction of the great cities. They suggest that occasional instances of decaying towns, such as come within the experience of all who know the country, are no mere isolated cases, but that they fall into line as part of a movement that seems to threaten all of our smaller towns, and that has already affected almost every county in the kingdom. It seems hardly too much to say that the complete elimination of the small country town is threatened, and the future of these little local centres seems bleak indeed. The remarkable feature is that of this astonishing state of things the census reports should take practically no heed, and that the collation of the details necessary for its presentation should be left untouched. Yet in many of these towns decreases have been registered in three or four successive enumerations, and in other cases where there is not this continuous decrease, the figures for 1901 are the lowest recorded within a period of thirty years.

When the character of the towns involved is taken into account, the matter becomes almost more serious, for figuring in this list are the names of places that have borne a gallant part in our long and chequered history. Cathedral cities and county towns, seaports famous in the past, centres of agriculture and of local industry, towns full of ancient memories, still cherishing visible reminders of past glory, towns famous in literature and history, and those that have been illumined by their connection with some national hero—all of these appear in the long and melancholy list. Here are a few of them—old towns all. Chosen almost at haphazard they stand as towns that have sturdily played their part in the rough-and-tumble sport of the centuries, only to show signs of failing before the more unkindly pressure of the modern spirit. There is Launceston, in the far West; Tavistock, that gave to England in her hour of peril, the admiral who, "nor devil nor Spaniard

feared," and returned as her member the first great leader of the House of Commons; Crediton, seat of a Saxon bishopric; Glastonbury, the town of ancient ruins among the apple-orchards; Shaftesbury, throned on its eyrie, far above the fair vales of Wessex, and linked imperishably with the work of a modern master of literature; Blandford, with its long roll of honoured sons; Bradford-on-Avon, the tiny town that has yielded its old industrial fame to its northern namesake, and lives among its memories of the past; Tenterden, in Kent, with its ancient privileges of the Cinque Ports; Stroud, the town of the Cotswolds, with an Elizabethan Town Hall; Chepstow, where the ruins of Fitz Osbern's mighty castle still guard the junction of Wye with Severn; Monmouth, the Saxon stronghold, whose very appearance to-day is almost of the middle ages, proud of its honour as birthplace of the great Henry V.: in the East:—Ely, the jewel of the fens; Huntingdon and Godmanchester, the twin-boroughs that join hands across the sedgy Ouse, in whose streets the great Protector played—if he ever played at all—in his schooldays; Stamford, town of many churches and centre of scholastic life in medieval days; on the Welch marches:—Flint, whose keep still guards the Dee, as it did in those far-away days when Percy of Northumberland there betrayed Richard II.; and so on to those northern heights where the ruins of Richmond—"the warder silent on the hill"—front the glorious dales of Yorkshire. All of these, and they are but a few of many, have been towns of importance in their day. Almost all of them have been Parliamentary boroughs until recent times. Now they seem to stand as mute reminders that the amazing development of city life, consequent upon the industrial expansion of the nineteenth century, is altering the whole economy of our country. From broad acres and fertile valleys, from village and farmstead, the great cities have drawn their toll of recruits. It would seem that already the same process of absorption is depleting our smaller towns, and the figures here submitted seem to confirm the fears of those who hold that the population of the future is likely to be confined almost exclusively to cities. At all events here are the signs of a tendency that suggests a future state with a sparsely-peopled countryside as one extreme and huge aggregations of humanity as the other, and lacking the connecting links so happily supplied at present by the quiet old country towns.

Here then are the facts. It can hardly be other than a surprising and disquieting circumstance that so large a poportion of our smaller towns should be diminishing in population, many of them to a serious extent. While it is probably true, as I suggested at the outset, that everyone can recall from his own experience some single instance of a declining town, it is hardly conceivable that there is any general knowledge of the fact that so many as 165 English towns with populations varying from 2,000 to 20,000, are on the down-grade. But though this is the case it would be foolish to generalise as to the causes of decay. If some machinery were brought into play that could elicit from persons competent to judge, an authoritative opinion as to the cause or causes of decadence in every instance, it would almost certainly be found that in no two cases would the reasons offered be identical, and for this if on no other ground generalisation would be absurd. But it is almost equally certain that out of the clash of divergent opinions there would emerge certain clear causes common to many instances. Indeed, it is hardly too much to claim that certain laws applicable to groups of towns might be found to be tolerably stable in their operation. The question thus arises whether it is not desirable to set on foot some national inquiry for the consideration of this important matter in all its bearings. It is no obscure or trivial circumstance: it is rather matter for national concern.

This suggestion is reinforced by a knowledge of the many things that are bound up with the main question. It requires but little thought to perceive that certain forces are in operation to produce this state of affairs in definite instances, and as little to perceive that remedial measures must conform to certain conditions; but it is quite clear that, as enquiry came to be pressed, unsuspected relations would flash into light; the interdependence of this great question and others of no less gravity would gradually be realised. It is highly important, therefore, that any enquiry to be successful should be comprehensive and authoritative.

As an instance of the questions that are inextricably involved with this, one may mention the general question of railways and road traffic. There are many instances of arrested growth because a town has been left aside by the railway, while, on the contrary, mere villages have developed astonishingly as soon as they have been brought by the

railway into closer connection with the industrial life of the kingdom. These opposing influences do not, however, represent the whole of the power of railways, and it is by no means an uncommon thing to hear the suggestion seriously put forward—especially in country districts—that the coming of the railway has been the precursor of decay; that convenience of access to larger towns has served, not to bring prosperity, but to divert business. Thus while amid these varying opinions, it is futile to dogmatise as to degree, it is certain that the questions of railway expansion and, the shifting of population are most intimately related.

Following up this idea it will be seen that the present forms an appropriate time for enquiry on account of the recent development of light railways. Since the passing of the Light Railways Act of 1896, many supplementary lines have come into existence. Some, at least, have justified their creation, and though there may be as yet hardly sufficient evidence in the success of existing lines to justify private enterprise in netting the country with light railways, yet there does arise the question as to whether the opening up of fresh channels of business in purely rural districts, would not bring about the revival of life in those towns favourably situated as centres of local life and interchange, a position at present denied to them because they lack that facility of communication vital to prosperity in these days. It may fairly be urged in objection to this view, that practically all the decaying towns are even now reached by the railway. That is true, but in many cases these towns represent the termination of a railway. Instead of being themselves the centre of a nervous system, they are the nerve-tips only, and the position might conceivably be vastly different if they were drawing in life instead of being merely drawn upon.

Again the question of the future of our great trunk roads in connection with the development of the motor-car must obviously have a great effect, one way or another, on the distribution of population. Even those who know most about the great change in locomotion are reluctant to express any opinion as to the direction in which the development will exercise its tremendous influence. But most assuredly these influences, whatever form they may eventually take, are bound to affect very materially in some form or other the distribution of our population, and in that respect they establish their right to be treated in relation with the question of our diminishing towns. So, too, with the development of electric tramways, which seems to be proceeding along the lines of linking together town with town. It is impossible to forecast the exact future of this form of transport, but it is easy to see that it will have a great bearing upon the general question of the ultimate settlement of population.

But if these are matters whose relation to the specific question though certain are yet somewhat obscure in their ramifications, there are at least two matters of quite direct connection and importance that might well occupy attention in any such investigation as I have suggested. Without in any way reverting to such measures as are frankly protective in their operation it is surely possible to bring about a greater correspondence between needs and opportunities in the matter of particular industries. The modern tendency to remove some classes of manufacturing businesses outside the radius of great cities is in many respects beneficial. This tendency has operated to revive the prosperity of certain towns, without in any way impairing their amenity. There are industries that are not dependent upon a position within one of the large cities, trades that can be more heathily and profitably carried on in smaller towns, and the removal does by no means imply the introduction into quiet country towns of the worst features of city life. Here there is a definite line of enquiry that could hardly fail of profitable results for such an investigation as I have shadowed forth.

But there is yet another aspect of the case that in one respect at least is more urgent than those already mentioned. It is just in the small towns of England that we find the fullest material evidence of the past history of the country. With but few exceptions the larger cities and towns have come to present a wholly modern appearance. This was of course inevitable. The demands of traffic and industry are imperative. Where modern claims and ancient interests clash, it is but rarely that the latter can be considered. Therefore there has been in the last century or so, as an inevitable accompaniment of expanding city life, an enormous destruction of ancient buildings. As a consequence, it is to the smaller towns that we must turn for those material records that enable us to reconstruct the life of the past and to understand its bearing on our history. The names of towns mentioned earlier in this paper as specific instances illustrate

my meaning. By reason of their position in the past and of their corporate entity, they have been adorned with many buildings of significance and interest. Because the towns have not kept pace with the march of modern development, they have been enabled to retain the buildings that in greater cities become an anachronism and an obstacle to growth. It is just in these smaller towns then that we find in abundance the great church establishments, abbeys, priories, nunneries, churches, hospitals, schools, shrines, guest-houses and tithe-barns, and the finest surviving examples of public and domestic architecture—palaces, castles, guildhalls, town gates, fragments of walls, market halls and market crosses, manor-houses, inns, bridges, and mills. But, while these relics of the past have survived the dangers incident to city life, they seem to be threatened with another danger no less grave. If, as seems likely to be the case, many of the towns most richly endowed with ancient memorials, continue to decrease decade by decade, is there not a very real danger that waning prosperity and diminishing population may lead in time to inability properly to safeguard the invaluable treasures of these towns? This may arise not alone from such a lack of funds as might follow commercial decay, but also from the subtle workings of those feelings of hopelessness engendered in whole populations by a perpetual fight against dwindling opportunities and accumulated misfortune. Of all the dangers arising from the presence of large numbers of declining towns this is, in one respect, the most important. It is so because any injury caused by neglect of the old buildings is irreparable. Once damaged, they can never be restored to their original condition. Once destroyed, they can never be replaced, and this I regard as one of the strongest arguments in support of a national enquiry into the wide questions raised by the spectacle of so many declining towns. I think it is also clear that the work to be done is of such a character that it is worthy to occupy the attention of the ablest men of the day. Royal Commissions have often been appointed to investigate matters less wide in their bearings, less important to the welfare of the State, and it hardly seems too much to claim that here is a subject that calls for the patient investigation and authoritative report of a specially appointed commission. There is one respect, at least, in which such a Commission would find itself favourably situated as compared with a similar body dealing with the depopulation of the villages. With regard to the latter there is a melancholy agreement among the chief authorities on this subject, that even if the tide of population could again be turned towards the villages, the housing question would form an almost insuperable barrier. It seems impossible to build cottages in consonance with present-day standards that can be made to pay for their erection out of the scanty sum available for rent from agricultural wages. But in the towns this difficulty is not an insurmountable one. The return even in the smaller towns is such as always to ensure the erection of sufficient houses to meet the demands of any increase in the population. Such a Commission would start, therefore, with one very important point in its favour, and whatever might be the result of its deliberations or the measure of its success it could not fail to secure an amount of information that would be of incalculable benefit to the country and of illumination for the problems of the future.

If, unmoved by practical considerations, the nation should take no steps to arrest a decay that seems to be settling down into a prominent feature of our national life, then those who love the country best can but give expression to an unavailing regret. From the sentimental point of view it is only possible to understand the position of the country town by imagining the English landscape bereft of the little towns. It would be to withdraw from our fairest views one of the most delightful elements of beauty. Of all the sons of Britain sent out across the seas to labour under alien skies there can be few to whom almost the dearest thing in retrospect is not their memory of some loved old town, and there can be none save those born of the city—most hateful of fates—who have never experienced the kindly associations that cluster round the country towns. Nowhere else in the wide world have the little towns the same sense of enduring identity with the landscape. In their peace and charm, in their attraction and beauty, we find a haunting—a perennial interest. In all the diversity of English landscape, they take their place unchallenged. Framed and fashioned out of the hills around, coloured and weathered by the winds that sweep the insentient earth, they stand serene and beautiful. There are towns on windy cliffs whose church tower stands a beacon by day, whose lights flash signals across the encircling deep by night, towns that nestle in some corner

of sheltering hills, the red roofs peeping from "orchards bedewed with spray-drift," towns that stretch out quaint arms from old quays and harbours, towns that slumber in the clear air of the fens, whose roofs are outlined with magic beauty when the sun floods the wide flats at his setting, towns that lie within the fold of a winding river valley to mark the ford that has been used for centuries, towns that are hidden from sight till one drops upon them all unsuspecting, and towns that crest the ridges and dominate a county. They are all dear in their infinite charms, and if before the imperious pressure of modern claims they should be compelled to give way, and no hand be stretched out to save them, then the lover of English scenery, and the student of the past, would together mourn an irreparable loss.

DISCUSSION.

The CHAIRMAN, in proposing a vote of thanks to Mr. Anderson for his interesting paper, thought those present would agree that the author was a man who loved the country, and his descriptions of it showed a power which many would like to possess. But the question had to be considered from a matter of fact rather than from a poetical point of view. The decline of the country and small towns was entirely due to the desire of the people to get something they thought was better than what they already possessed, and there was no doubt that people went from the country to the larger towns purely and simply because of their many attractions. In considering the Tables given by the author, he had been struck by the fact that apparently the most popular size of town was one with between 50,000 and 100,000 inhabitants, that size of town showing respectively the largest and smallest increase and decrease in the Tables. The author had very truly said that many of the manufacturing industries in this country were finding their way into provincial towns which were suitable for such industries. He ventured to say that that inclination would go on increasing, because at the present moment many things tended in that direction. If such a development took place, the country, which the author so much loved, would be destroyed by smoky chimneys. The chief point of consideration, however, was to find employment, under the best conditions, for the large number of people there were in the country; and in that connection the decentralisation, which at present was taking place, was a very wise step. The question of inter-communication was also a serious one; railway communications must be good; and fairly cheap labour was essential. In certain industries with which he was intimately connected Rugby had been chosen as a suitable town embracing those advantages. There was one thing which was having an important effect in regard to the repopulation of the country, viz., the enormous increase in local rates and taxes. This was having a most prejudicial effect on all manufacturing industries. In particular industries of which he had intimate knowledge, the direct and indirect effect of the rates raised by the municipalities from industrial undertakings was to take away about 50 per cent. of their earnings. Moreover, they had no representation on the body which spent the money. The paper showed that there existed a great want of population in the country towns; those who governed the destinies of the people on the municipalities were doing their best to supply the want.

The vote of thanks having been carried unanimously,

Mr. ANDERSON, in replying to the Chairman's remarks with regard to the rates and the general future of municipalities, said that Mr. Wells recently read a paper before the Fabian Society in which he suggested that the present system of life led one to suppose that the municipalities of the future would have to be very much larger than they were at present; for instance, he suggested that Guildford, because it was the residence of a great many London people, was just as much a part of London as Battersea or Holborn; and that in the future, in order to adjust all the anomalies of taxation and rateability, it would be necessary for the municipalities of the country to make a much wider sweep. He thought that would be a very suitable subject of enquiry for the Commission he had suggested. With regard to the question of manufactures, he knew of instances where certain manufactures had been carried on in small country towns without in any way making them approach the worst features of city life. The whole question at present was left to private enterprise; but a national Commission might be able to make suggestions with regard to that introduction of industries, and the responsibility of carrying them on; and by benefiting certain constituent parts of the nation the country as a whole would be benefited.

ADULTERATION OF ARTIFICIAL MANURES.

In the course of their inquiry into the working of the Fertilising and Feeding Stuffs Act, 1893, the Departmental Committee appointed by Lord Onslow, whose report has just been issued, found that various frauds are practised by sellers. One method is grimly ingenious. It is to sell manures and cakes of poor quality at an exorbitant price, *i.e.*, many times above the price usually charged by the trade for stuff containing the same amounts of the various constituents. Farmers often judge of the value by

the price, and are apt to assume that a higher-priced cake is richer. In Anglesey a favourite device is the addition of sand to a 25 per cent. superphosphate so as to reduce the percentage to, say, 13 only. The mixture is sold with a guarantee of 13 per cent., so that no action can be taken, but it sells for little less than genuine superphosphates with twice the amount of phosphates. Then, again, a material is sometimes sold as a fertiliser when it really requires to undergo some treatment before it is ready to be applied to the land; feeding stuffs are sometimes adulterated with ground oat husks; invoices sometimes bear a notice that "all feeding stuffs, notwithstanding their trade name, are prepared from more than one substance or seed, unless the contrary is specifically stated." This last notice, it is thought, would not protect the vendor under the Merchandise Marks Act, although it is sufficient to do so under the Fertilisers and Feeding Stuffs Act.

The Committee have come to the conclusion that "the Act of 1893 can in no sense be described as a failure." It has acted as a beneficial deterrent against carelessness and fraud, but it has not been so entirely successful in the suppression of fraud as the framers of the Act of 1893 anticipated. And those who most required protection have benefited least. "The larger and more intelligent farmers," says the Report, "can, as a rule, take care of themselves.". Their operations are conducted on a considerable scale, and they are usually in a position to obtain their supplies from merchants in a large way of business, or even from the manufacturers direct. Moreover, being a man of greater general education, the large farmer is better able to discover whether there is anything wrong with a consignment. In the case of small men the relations between buyer and seller are a frequent bar to their taking action. Either the purchaser is, in many cases, a personal friend of the merchant, and does not like to appear to cast a doubt upon him by having his goods tested; or the farmer obtains his manures upon credit, and, being indebted to the merchant, is afraid of offending him. And there is the general unwillingness to incur the cost of analysis, or the responsibilities connected with litigation.

The Committee point out that under the Act of 1893 the seller is not required to give any statement of the constituents of a fertiliser where the sale is of less than half-a-hundredweight. It was strongly urged upon the Committee that this minimum should be abolished, and they concur in the recommendation. They say that "considerable quantities of worthless manures are sold in parcels of a few pounds, often in tins, principally to occupiers of allotments and small gardens in the neighbourhood of towns, the price charged being frequently exorbitant. Our evidence has shewn that the opportunities for, and practice of, fraud are proportionate to the smallness of the amount sold, and to the poverty of the purchaser." The Committee recommend that the section of the Act of 1893 exempting sales of less than half-a-hundredweight from its provisions should be omitted, and, among other things, that powers shall be given to Local Authorities to appoint persons, with the approval of the Board of Agriculture, to act as official samplers.

INDIAN WHEAT EXPORTS.

Attention was lately directed in the *Journal* (16th December last, 1904, p. 105) to a striking passage in the second article by the Military Correspondent of *The Times*, on "Our Warning from Manchuria," in which some figures relating to the imports of wheat into England during the past two years were quoted, and the conclusion was arrived at that, with the cessation, in case of war, of Russian exports by sea, "India stands out as our first and most important source of supply," and has become "the granary of the Empire." In a recent issue of *The Anglo-Indian Review*, Mr. Herbert Birdwood adduces statistics of Indian wheat exports since 1872-73, which strongly enforce this view. In the five years which ended with 1872-73, the annual average of exports, though swollen by an unusually large export in 1871-72 to Persia, where there was widely prevailing distress, amounted only to 326,664 cwts. (or 16,332 tons), worth £127,702. But in January, 1873, on the representation of the Bombay Chamber of Commerce, the seven per cent. *ad valorem* export duties on Indian wheat were repealed by Lord Northbrook's Government; and in the very first year after the repeal exports rose to more than 1¾ millions of cwts., the bulk of the increase being due to trade with the United Kingdom. The exports have not since, as pointed out by Mr. Birdwood, fallen below a million cwts., except in 1900-01, though "there have certainly been violent fluctuations in the trade in the last 30 years which may be ascribed generally to variations in the seasons. When the Indian crops are poor, India can spare but little; and again, when crops in the West, and the far West, are abundant, and prices are depressed, the Indian exports are only, as might be expected, moderate, but when the yields in Eupope and America, or in America alone, are moderate, then India finds an opportunity and exports huge quantities of wheat; and to enable her to do this it is not improbable that she has, at times, as has been conjectured, drawn largely from her buried stores. Any way, the net results obtained have served to place in a clear light the foresight and sagacity of Lord Northbrook's Government in adopting so readily the proposals of the Bombay Chamber of Commerce, and thus securing most material benefits for the people of India. As early as in the third year after the repeal of the duties (that is, in 1875-76) the exports rose to 2½ millions of cwts., then in 1876-77 to more than 5½ millions, and in 1877-78 to more than 6 1-3rd millions. Then

there were two comparatively lean years, as there have been also within the past decade, but in 1880-81 the figures rose to nearly 7½ millions, and in the following year to nearly 20 millions. In some subsequent years the figures went as high as 21 and 22 millions and higher, and in 1891-2 they reached nearly 31 millions of cwts. (or about 1,542,000 tons) valued at nearly 14¾ millions of £ (Rx). In the year 1903-4 the exports amounted to nearly 26 millions of cwts. (1,297,000 tons) or considerably more than double the exports of the preceding year, and about 2 3-5th times the annual average of the preceding five years. The exports for the current year will probably exceed even these figures."

"For the six quinquennial periods which have elapsed since 1872-73 the following figures show the total exports in tons for each period and the annual average for each period:—

Periods. Five years ending with—	Tons Exported.	Annual Average (Tons).
1877–78	172,000	34,400
1882–83	446,000	89,200
1887–88	936,000	187,200
1892–93	4,603,824	920,764
1897–98	1,815,830	363,160
1902–03	2,493,693	498,736

The sterling value of the exports of the last quinquennial period amounted to £19,076,694, or nearly £4,000,000 per annum, notwithstanding the comparatively poor export of 27,368 tons in 1900-01, the value of which was only £258,933. It is scarcely necessary to go on multiplying figures and facts all tending to the same conclusion—that India may now be safely regarded as the destined "Granary of the Empire"; and as increasing exports mean wider cultivation (even though, at times, resort may have been had to buried stores), and also a perceptible addition to the comfort and resources of cultivators, there can be no question as to the advantage which has accrued to India from the wise policy inaugurated by Lord Northbrook. In the Punjab alone, the area under wheat, which was less than 7 millions of acres in 1877-78, increased to more than 7¾ millions in 20 years."

The answer to the important question whether, with a larger output, the quality of Indian wheat has been maintained at the highest possible level, is, in Mr. Birdwood's judgment, disappointing. "The same quality of grain," he says, "is not, of course, to be expected in all districts where it is grown. Wheat is the principal crop on irrigated lands extending over a wide tract of country; and the conditions of soil and climate necessarily suit the crop better in some places than in others. Yet even in some districts where the best crops are not generally expected, excellent results have been obtained by special attention, especially as regards the keeping of the wheat clean for the market. A high authority, a Revenue officer of long experience, tells me that this has been the case in the Ankleswar district of the Broach Collectorate in Guzerat, where the wheat is excellent, although in the Wagra district of the same Collectorate it is only fair in quality. He classes the Bombay wheat generally (except that grown at Ankleswar) as moderate, almost poor. In the Ahmedabad Collectorate, also in Guzerat, some of the Dholka wheat is good, but it is not great in quantity. In the Dekhan and Southern Mahratta country a hard yellow grain is produced, and is preferred to any other in the older provinces of the Bombay Presidency, and is also in demand in the Mediterranean countries for macaroni, but is not liked in England; and is of inferior value to the wheat grown in Sind, and to the Punjab wheat, white and red. The soft red wheat of Guzerat, which is classed as good, is not so good as the soft white wheat of the Nerbudda Valley, which is, indeed, the best in India. Some years ago experiments were made in Guzerat in growing soft white grain; but in three years the produce was undistinguishable from the soft red wheat. An expert on wheat, Sir John McDougall, writing to Lord Cross in 1889, gave it as his opinion that Indian white wheats, 'when separated fro m all admixture,' were of very fine quality, and 'equal to the finest in the world.' It is the admixture of foreign substances, whether earth, or the seeds of other crops grown along with the wheat, according to the favourite Indian fashion, which has brought a slur on Indian wheat, which apparently will not be altogether removed so long as the form of contract in force between the Indian exporter and the English purchaser is maintained, whereby a certain 'refraction,' whether 5 per cent., or 4 per cent., or 3 per cent., is provided in respect of such admixtures, any excess above such percentage being paid for by the exporter, whereas he receives no better price if the wheat contains less than the percentage. Thus no encouragemant is given to the cultivator or the middleman to supply the exporter with cleaner wheat. On the contrary, the temptation, at all events to the middleman—for the cultivator in this matter can scarcely be held to be responsible—is to adulterate to the full extent of the refraction. It would not pay him, for instance, to sell grain to the exporter with only 2 per cent. of refraction, if the exporter himself accepts a higher rate. It has been said over and over again that if merchants insist on clean grain they will get it. If the consuming countries wish to receive cleaner wheat and will pay for it, exporters will adapt themselves to their requirements. Indeed, so far as exports from Bombay are concerned, the exporters, as represented by their Chamber of Commerce, long ago pressed for a reduction of the refraction to two per cent., with the express object of improving the character of the wheat, but their views have not as yet prevailed. The necessity for improving by mechanical means the quality of the wheat before shipment has not, however, been lost sight of in India, and the matter is indeed one demanding earnest attention. In 1889, Sir John McDougall insisted

on it as one of national importance, inasmuch as, in case of war, all sources of European wheat might be stopped, and it would be desirable that wheat should be shipped to us from our colonies in a condition fit for immediate use. He said that it would be quite impossible to grind for human food the dirty wheat then shipped from India, so long as it was uncleaned. All other Indian products were shipped in a better condition. In the same year, Lord Cross, in addressing a Conference on Indian wheat impurities, said that the percentage of dirt amounted, in some of the Indian wheats, to 7, 8, and 10 per cent., and that we were incurring the useless and foolish expense of importing a million cwts. of dirt every year from India. An expert who speaks with authority on this subject gives me as the result, at the present moment, of an adherence to the old form of contract and the refusal to accept 'mutual allowance contracts,' that freight will have to be paid in the current year 'on some 30,000 to 40,000 tons of dirt.'"

ADVANTAGES OF COAL-CUTTING MACHINES.

Among the subjects touched on by the Royal Commission on Coal Supplies, the final report of which has just been published, is that of coal-cutting machines for the working of thin seams. According to several witnesses, the chief advantages of coal-cutting machines are:—(1) That an increased percentage of large coal is obtained, and the coal got is in a firmer and better condition. (2) A more regular line of face is obtained, which facilitates ventilation, and leads to more regular and systematic timbering; and, the weight being more regular and uniform, the roof can be more easily kept up. The greater rapidity of working also tends to keep down the cost of repairs, and causes less damage to overlying seams and to the surface by reason of the subsidence being more even. (3) The regular and systematic working tends to increase the safety of the workmen. (4) Seams which either by reason of their thinness or hardness, or both, could not be worked at all, or could only be worked at a profit in times of high prices, can be worked profitably by machines. (5) Holing is less frequently done, and when it is, there is much less small than in the case of holing by hand. (6) The output is increased and is more regular, and the work is more easily superintended. Fewer explosives are used for getting down the coal, while machine work is less costly than hand work, particularly in thin seams. Under certain conditions, however, coal-cutting machines cannot be worked to advantage; these are where the roof or floor is bad, where there are numerous faults or dykes, or where the seams are highly inclined, or where the coal is very soft. One effect of the introduction of electrically-driven coal-cutting machines on a large scale has been the extensive introduction of electricity, which is invaluable from the point of view of economy and general efficiency. It is said to be well adapted for every requirement of mining and for all the general purposes of a colliery.

RURAL HOUSING.

In a late number of *The Times* Mr. Cumming Macdona, M.P., had an interesting letter, in which he pointed out that all risk from destruction by fire may be eliminated by a simple process that makes wooden structures as incombustible as stone and iron, the process that Mr. Yerkes has applied to the carriages and platforms of his newly constructed subways. Mr. A. R. Steening has since reminded those interested in the subject that in the metropolitan area, under the London Building Act, 1894, section 201, wooden houses can be erected. Prior to 1894 this could be done under the Building Act of 1855, which has the same section as the 1894 Act. It may be noted, too, that where rural authorities are content to adopt the last new by-laws for rural districts, there is no obstacle to the erection of wooden houses. By-laws 4 and 5 are the only clauses proposed affecting the walls of buildings. In other respects, as to size, material, position, strength, &c., the builder is entirely unfettered. Clause 4 makes it obligatory upon the builder of a new dwelling-house to have "a proper damp course of sheet lead, asphalte, and slates laid in cement, or of other durable material, impervious to moisture, beneath the level of the lowest floor, and at a height of six inches above the surface of the ground adjoining such wall." And clause 5 confines itself to directions as to walls of buildings when carried up above any roof, flat, or gutter, so as to form a parapet. Of course, if a district council is not content with the powers suggested by the Local Government Board in its model by-laws, it can apply for urban powers which give the right of interference so bitterly complained of.

The conditions which should influence a District Council in applying for urban powers are clearly indicated by the Local Government Board when it says "Portions of many districts are distinctly urban in character, and the development of building is constantly changing the aspect of the country, and it devolves on rural District Councils to endeavour to apply to the several parts of their districts such regulations as the circumstances may, from time to time, seem to require." Unfortunately, the District Councils are not inclined to differentiate. A series of by-laws may be made for part only of a contributory place where the circumstances justify this course, but the councils prefer powers over the whole district, with the result that the village housing problem is made much more difficult of solution than otherwise it might be. It is hoped that in the coming session time may be found to deal with this very important question.

ADMIRALTY CHARTS.

The following is the official list of charts issued by the Hydrographic Department, Admiralty, in November and December last:—

New Charts.—2287—Tidal streams round the British isles. 2498—Scotland, west coast:—Southern part of the sound of Raasay and Inner sound. 3441—Scotland, west coast:—Gairloch. 3422—Scotland, Hebrides:—East loch, Roag. 3444—Ireland, south-west coast:—Crookhaven, Ballydivlin and Toormore bays. 3467—Iceland (plans on the north coast):—Kalshamarsnes. Blondaos, Selvig, Hagenesvig, Sandvig, Husevig, Snerstastadir, Thorshavn. 3462—British Columbia:—Southgate group and anchorage. 3464—Alaska; harbours and anchorages in. 3477—Africa, west coast:—Port Forcados. 628—Africa, west coast; Bight of Biafra:—Opobo river. 839—East Indies; Andaman islands:—Port Meadows and Kotára anchorage. 3471—Sumatra:—Banka strait. 3463—Philippine islands, Mindanao, south coast:—Dumankilas bay. 3449—China, east coast:—Amoy, outer harbour. 1260—China, north coast; Ching tsu shan to Chifu bluff, including Chifu or Yentai harbour (plan, Chifu or Yentai landing). 3468—China, north-east coast (plans on the coast of Shantung:—Malan and Lungyen coves; Yangyuchih bay; Litau bay; Ayleu bay). 3457—China, north coast:—Litau bay to Chutau, including Wei hai wei harbour. 3019—Japan, Kiusiu; north-west coast:—Imari wan and approaches (plan:—Hibi Suido). 2441—Japan, Tsugaru strait. 3455—Japan, Nipon, south coast:—Aikuchi bana to Yeboshi bana, including Nagashima wan and Kanzaki wan, Nishiki wan. 3460—Japan, Nipon, south coast:—Ino hana to Aikuchi bana, including Kada wan and Owashi wan; Kuki ura. 3458—New Guinea, plans of anchorages on north-east coast:—Buna roads; Oro bay; Port Harvey; Anasari harbour; Pusi Pusi harbour; Wamnea anchorage; Kitava island anchorage. 3436—New Zealand, east coast:—Plate island to Cape Runaway. 1103—North Pacific ocean:—Palao or Palew islands; Korror harbour; Helen reef; Mapia island; Los Martires. 3461—Pacific, Tubuai islands:—Vavitao or Ravaïvaï. 87—Spain and Portugal, west coasts (plan added:—Sines bay). 1128—Mediterranean sea, Sardinia; ports in (plan added):—Arbatax road. 2634—Mediterranean Sea, Syria; Ras En-Nakura to El Arish (plan added):—Yafa anchorage. 369—Cape Verde islands (plans added):—San Filippe and Encarnaçao anchorages; Port St. Jago (new plans):—Porto Praya; English road (Mayo I.). 3004—Iceland, places on the south and east coasts (plan added):—Vastmannaeyjar. 652—Africa, east coast (plan added):—Mozambique anchorage. 1809—Africa, east coast: Mozambique to Ras Pekawi (plans added):—Port Duarte Pedroso; Belmore harbour; Port Nakala. 764—South-west Pacific, New Hanover, &c. (plan added):—Peter haven. 55—South-west Pacific, New Ireland, &c. (new plan):—Nusa harbour.

Charts that have received additions or corrections too large to be conveniently inserted by hand, and in most cases other than those referred to in the Admiralty Notices to Mariners:—1167—England, west coast:—Bury inlet. 1543—England, east coast:—Yarmouth and Lowestoft roads, &c. 1625—England, east coast:—Seaham harbour. 2296—Baltic:—Gulf of Bothnia, sheet 1. 2646—France, west coast:—Bourgneuf to Ile de Croix. 2989—France, west coast:—Entrance to the Loire river. 2664—France, west coast:—Point d'Arcachon to Pointe de la Coubre. 92—Spain, west coast:—Cape St. Vincent to Gibraltar. 1567—Africa, north coast:—Approaches to Bona. 308—North America:—Gulf and river of St. Lawrence. Plans in. 2818—United States, east coast:—Hampton roads. 969—South America:—Pernambuco roads. 551—South America, east coast:—Port San Antonio. Port St. Elena. 461—Africa, west coast:—Wari and Benin rivers and creeks. 622—Africa, west coast:—Bonny and New Calabar rivers. 1810—Africa, east coast:—River Zambesi to Mozambique harbour. 665—Africa, east coast:—Zanzibar harbour and its approaches. 1235—Persian gulf:—Mouth of the Euphrates. 1419—Bay of Bengal. Andaman islands:—Long island to port Blair. 1348—Borneo:—Natuna islands. 1180—China, east coast:—Approaches to Hongkong. 2618—China sea. Formosa, north coast: Ke lung harbour. 1798—China, north coast:—Kwang tung peninsula, &c. 1259—Korea:—Fusan harbour. 2875—Japan. Naikai (Seto uchi). 2924—Australia, east coast:—Cape Grafton to Hope islands. 2923—Australia, east coast:—Hope islands to Turtle group. 939—New Guinea:—Cape Nelson to Hercules bay.

These charts are issued by Mr. J. D. Potter, 145, Minories.

OBITUARY.

Sir George Cotton, J.P.—Sir George Cotton, one of the leaders in the building up of the cotton-spinning industry in India, died suddenly on the 5th inst., at the Langham Hotel. He was born in Ireland in 1842. In 1863 he went to Bombay as manager of the East India Cotton Agency, and at once became prominent in the business and public life of that city. In 1870 he started, with Mr. James Greaves, the firm of Greaves, Cotton, and Co., Bombay, and J. Greaves and Co., Manchester. A correspondent of *The Times* says—in course of time the firm started or secured the agency for ten or twelve mills, and now it has under its control some 300,000 Indian spindles. Sir George Cotton took a most active part in the formulation of local com-commercial opinion, and in the civic and philanthropic life of Bombay, serving for years on the local corporation, of which he was twice elected president. He was a Fellow of the University of Bombay, and held the office of Sheriff. The unique influence

Sir George Cotton exercised over the working classes in Bombay was a most valuable factor on the side of law and order in times of public unrest. In the great famines of 1897 and 1900 Sir George took a leading part in administering the charitable relief funds locally collected and those assigned to Western India from the large amounts subscribed to the central organisation in Calcutta from Great Britain and various parts of the Empire. Sir George Cotton's standing in Western India was stated in a farewell address presented to him at the town-hall by his fellow citizens when he finally transferred his home to Manchester four or five years ago. "You will carry home with you to England," said the address, "the affectionate regard of many races and creeds, who will long remember you as a just, broad-minded, and public-spirited citizen." He was elected a member of the Society of Arts in 1891, and received the honour of knighthood in 1897.

A. C. Cronin.—Mr. Alfred Charles Cronin, solicitor, died on the 6th inst., at Assouan, Egypt, aged 64 years. Mr. Cronin was elected a member of the Society of Arts in 1899. In the same year he served as Master of the Clothworkers' Company, of which company he was an active and influential member.

GENERAL NOTES.

Nobel Peace Prize.—The Board of Education have received through the Foreign Office an intimation that, in order to be eligible for the Nobel Peace Prize, which will be awarded in December, 1905, candidates must be proposed to the Nobel Committee of the Norwegian Parliament before February 1st next. The following persons alone are qualified to recommend candidates:—1. Members of the Nobel Committee of the Norwegian Parliament. 2. Members of the Legislatures and Governments of different countries. 3. Members of the Conseil Interparlementaire. 4. Members of the Commision du Bureau International permanent de la Paix. 5. Members and Associates of the Institut de Droit International. 6. Professors of Law and Political Science, of History and of Philosophy in the Universities. 7. Persons who have received the Nobel Peace Prize. The Nobel Peace Prize can be granted to an institution or an association, not only to an individual. Inquiries for further information should be addressed to the Comité Nobel du Parlement Norvégien, Victoria Terrasse 4, Kristiania, Norway.

Beet Sugar.—A late circular of the West India Committee contains some figures throwing light on the enhanced price of sugar caused by the shortage of the beet crop:—On October 1, 1903, the visible supply of sugar of all kinds was 1,879,031 tons, and the beet crop of the season 1903-4 yielded 5,864,938 tons, the cane crop 4,423,800 tons, and the American beet crop 210,000 tons—making a total supply for the season of 12,377,769 tons. The total supply for the season 1904-5 is estimated at no more than 10,917,532 tons, arrived at as follows:—Visible supply on October 1 last, 1,434,532 tons; estimated beet crop of 1904-5, 4,685,000 tons; cane crop, 4,607,000 tons; American beet crop, 191,000 tons. Deducting the visible supply on October 1 last from the total supply of the 1903-4 season, it will be seen that the consumption of that season was 10,943 257 tons—25 725 tons more than the estimated total supply of 1904-5. Thus the total amount available will be short of the consumption, even assuming the consumptive demand to be no greater than in 1903-4, whereas the cheapening of sugar in Europe through the abolition of the bounties and kartels has largely increased the demand there. There is a slight increase in the cane crop, and a considerable development of cane sugar cultivation in the various tropical and sub tropical countries which are adapted to its growth, is expected.

The Sub-division of Australia.—The New South Wales Department of Lands has just published an interesting statement illustrated by diagrams. It shows the sub-division of Australia into separate colonies between 1787 and 1863. The facts are opportune at a time when the question of Federal capital territory is being discussed. In 1787 the Royal Commission to Governor Phillip declared the territory of New South Wales and its dependencies to be about half of all Australia. In 1825 Van Diemen's Land (Tasmania) was separated from the mother colony, who in 1836 had a big slice taken from her and named South Australia. In 1850 a portion was taken to form Victoria, and in 1859 the mother colony gave half of her then possession to form Queensland. In 1863 more than half of the half left was given to South Australia, and New South Wales shrunk to about a fifth of what she was in 1787.

The American Forestry Congress.—This Congress, recently held in Washington, was the largest of its kind since 1883. The interests represented included railway, mining, lumbering, agricultural, stock raising, and irrigation. Of the interesting facts brought out one was that the Pennsylvania railroad, owing to the scarcity of timber in the country it covers, is planting trees along its tracks, and along several abandoned tracks, to be used in the future for the making of ties. Another was that the mining industry of the United States uses more timber than the railroads.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, at 8 o'clock:—

February 22.—"Some Misconceptions of Musical Pitch." By John E. Borland. (*a*) *Visual*—due to conventional but inaccurate notation;

(*b*) *Aural*—volume of tone mistaken for depth, brightness for height. Illustrated by voices, instruments and diagrams. SIR WILLIAM PARRATT, M.V.O., will preside.

MARCH 1.—"The British Art Section of the St. Louis Exhibition." By ISIDORE SPIELMANN, F.S.A. SIR EDWARD POYNTER, Bart., P.R.A., will preside.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

MARCH 16.—"Manipur and its Tribes." By T. C. HODSON (late I.C.S.).

COLONIAL SECTION.

Tuesday afternoons at 4.30 o'clock:—

FEBRUARY 28.—"The Manufactures of Greater Britain.—I. Canada." By C. F. JUST, Canadian Government Service in London. The RIGHT HON. VISCOUNT RIDLEY will preside.

APPLIED ART SECTION.

Tuesdays, at 4.30 or 8 o'clock:—

FEBRUARY 21, 8 p.m.—"The Queen Victoria Memorial as compared with other Royal Memorials Abroad." By MARION H. SPIELMANN, F.S.A. JOHN BELCHER, A.R.A., President of the Royal Institute of British Architects, will preside.

CANTOR LECTURES.

Monday evenings, at 8 o'clock:—

DUGALD CLERK, M.Inst.C.E., "Internal Combustion Engines." Four Lectures.

LECTURE II.—FEBRUARY 20.—*Indicator Diagrams and Power Tests*—Diagrams from engines using coal gas, producer gas, blast furnace gas, petrol and heavy oils—Practical efficiencies and limitations in large and small motors for constant volume and constant pressure engines—Brake tests—Irregularities in diagrams, pre-ignitions, back ignitions, exhaust explosions, missed ignitions.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, FEB. 20...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Mr. Dugald Clerk, "Internal Combustion Engines." (Lecture II.)—Indicator Diagrams and Power Tests.

Society for the Encouragement of Fine Arts, 6½, Suffolk-street, Pall-mall, S.W., 8 p.m. Mr. Charles E. Keyser, "The Churches of Sparsholt and Childrey in the County of Berks, an Architectural description with Lantern Illustrations."

Imperial South African Association, Caxton-hall, Victoria-street, S.W., 8½ p.m. Sir Gilbert Parker, "South Africa and its Problems of To-day."

British Architects, 9, Conduit-street, W., 8 p.m. Mr. R. Blomfield, "Architectural Education."

Camera Club, Charing-cross-road, W.C., 8½ p.m.

Medical, 11, Chandos-street, W., 8½ p.m.

Victoria Institute, 8, Adelphi-terrace, W.C., 4½ p.m. Colonel G. Mackinlay, "Biblical Astronomy."

TUESDAY, FEB. 21...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Applied Art Section.) Mr. Marion H. Spielmann, "The Queen Victoria Memorial as compared with other Royal Memorials Abroad."

Royal Institution, Albemarle-street, W., 5 p.m. Prof. L. C. Miall, "The Structure and Life of Animals." (Lecture VI.)

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Discussion on papers by Mr. E. F. C. Trench, "Alfreton Second Tunnel," and by Mr. Dugald McLellan, "The Reconstruction of Moncreiffe Tunnel."

Statistical, in the Theatre of the United Service Institution, Whitehall, S.W., 5 p.m.

Pathological, 20, Hanover-square, W., 8½ p.m.

Zoological, 3, Hanover-square, W., 8½ p.m.

WEDNESDAY, FEB. 22...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. John E. Borland, "Some Misconceptions of Musical Pitch."

Geological, Burlington-house, W., 8 p.m. 1. Rev. John Frederick Blake, "The Order of Succession of the Manx States in their Northern Half, and its Bearing on the Origin of the Schistose Breccia." 2. Mr. Francis Edward Middleton, "The Wash-outs in the Middle Coal Measures of South Yorkshire."

British Astronomical, Sion College, Victoria-embankment, E.C., 5 p.m.

United Service Institution, Whitehall, S.W., 3 p.m. Col. Lord Raglan, "The Militia in 1905."

Royal Society of Literature, 20, Hanover-square, W., 8½ p.m.

THURSDAY, FEB. 23...Tramways and Light Railways Association (at the HOUSE OF THE SOCIETY OF ARTS), John-street, Adelphi, W.C., 8 p.m. Mr. Herbert Jones, "The Waterloo and City Railway."

Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

Royal Institution, Albemarle-street, W., 5 p.m. Prof. J. J. H. Teal, "Recent Work of the Geological Survey." (Lecture II.)

Electrical Engineers, 25, Great George-street, S.W., 8 p.m. Discussion on Mr. G. L. Addenbrooke's paper, "The Value of Overhead Mains for Electric Distribution in the United Kingdom."

Camera Club, Charing-cross-road, W.C., 8½ p.m.

FRIDAY, FEB. 24...Cyclist Touring Club, John-street, Adelphi, W.C., 8 p.m.

Royal Institution, Albemarle-street, W., 8 p.m. Weekly Meeting. 9 p.m., Dr. Marshall Ward, "Fungi."

Civil Engineers, 25, Great George-street, S.W., 8 p.m. (Students' Meeting.) 1. Mr. F. D. Flint, "Morecambe Sewerage: Method of Laying a 15-inch Cast-iron Sewer under the London and North-Western Railway." 2. Mr. H. M. Rootham, "The Reconstruction of Bow-bridge over the River Lea."

Architectural Association, 18, Tufton-street, S.W., 7½ p.m. Mr. F. J. Osborne Smith, "Country Houses and Accessory Buildings."

Clinical, 20, Hanover-square, W., 8½ p.m.

Physical, Royal College of Science, South Kensington, S.W., 5 p.m. 1. Dr. C. V. Drysdale, "The Curvature Method of teaching Geometrical Optics." 2. Mr. R. J. Sowter, "Exhibition of Dr. Meisling's Colour Patch Apparatus." 3. Mr. J. Schofield, "A Method of Illustrating the Laws of the Simple Pendulum, and an Exhibition of Strong Models of Optical Systems."

SATURDAY, FEB. 25...Botanic, Inner Circle, Regent's-park, N.W., 3¾ p.m.

Royal Institution, Albemarle-street, W., 3 p.m. Mr. D. G. Hogarth, "Archæology." (Lecture I.)

Journal of the Society of Arts.

No. 2,727. VOL. LIII.

FRIDAY, FEBRUARY 24, 1905.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

NOTICES.

NEXT WEEK.

MONDAY, FEBRUARY 27, 8 p.m. (Cantor Lecture.) DUGALD CLERK, "Internal Combustion Engines." Lecture III.

TUESDAY, FEBRUARY 28, 4.30 p.m. (Colonial Section.) C. F. JUST, "The Manufactures of Greater Britain.—I. Canada."

WEDNESDAY, MARCH 1, 8 p.m. ISIDORE SPIELMANN, "The British Art Section of the St. Louis Exhibition."

Further details of the Society's meetings will be found at the end of this number.

CANTOR LECTURES.

On Monday evening, 20th inst., the second lecture of his course on "Internal Combustion Engines," was delivered by Mr. DUGALD CLERK, M.Inst.C.E.

The lectures will be published in the *Journal* during the summer recess.

APPLIED ART SECTION.

Tuesday, February 21st; JOHN BELCHER, A.R.A., Pres.R.I.B.A., in the chair.

The paper read was "The Queen Victoria Memorial as Compared with other Royal Memorials Abroad," by Marion H. Spielmann, F.S.A.

The paper and report of the discussion will be published in a future number of the *Journal.*

PROCEEDINGS OF THE SOCIETY.

ELEVENTH ORDINARY MEETING.

Wednesday, February 22, 1905; JAMES E. MATTHEW in the chair.

The following candidates were proposed for election as members of the Society:—

Bacon, John Henry Frederick, A.R.A., 33, St. John's Wood-road, N.W.
Dickson-Brown, S., M.A., 31, Regent-square, W.C.
Earnshaw, Henry, 14, St. Mary-axe, E.C.
Evans, William Bailey, 20, West-parade, Huddersfield.
Fergie, George, Copiapó, Chili, South America.
Lello, Montague Nodes, 100, Belsize-road, South Hampstead, N.W.
Little, Robert, Singapore, Straits Settlements.
Minett, Richard, F.S.A.A., Municipal Offices, Cheltenham, and Cedar-lodge, Cheltenham.
Rolfe, William, 3, Adelaide-street, Charing-cross, W.C.
Steuart, James, 205, Clay-street, Baltimore, Maryland, U.S.A.
Tosh, William, J.P., M.I.Mech.E., P.O. Box 1132, Johannesburg, Transvaal, South Africa.
Williams, D. Neziah, 29, Tudor-terrace, Merthyr Tydfil, Glamorganshire.

The following candidates were ballotted for and duly elected members of the Society.—

Allen, Caleb J., Hillside-house, Lancaster.
Allis, Edward Phelps, jun., Palais Carnoles, Mentone, France.
Bingham, Charles Henry, 13, Great Brunswick-street, Dublin.
Cloud, John W., 82, York-road, King's cross, N.
Colabawalla, Dinshaw D., opposite Chira Bazar, Bombay, India.
Johnson, Edward, 605, Salisbury-house, E.C.
Kelly, Alexander, 100, Hyde-park-street, Glasgow.
Llanos, E duarde, 56, Leadenhall-street, E.C.

Parish, William Francis, jun., The Vacuum Oil Company, Ltd., 4, Norfolk-street, Strand, W.C.
Polden, Francis C., A.M.I.E.E., The Rhodesia Railways, Limited, P.O. Box 420, Bulawayo, Rhodesia, South Africa.
Schumacher, Harry A. P., 333, Calle Echaurren, Santiago, Chile, South America.
Sprague, Thomas Bond, LL.D., 29, Buckingham-terrace, Edinburgh.
Stuart-Fox, Julius J. S., The Western Telegraph Company, Ltd., Rio de Janeiro, South America.
Welbury, William, Middleton-crescent, Leeds.

The paper read was—

SOME MISCONCEPTIONS OF MUSICAL PITCH.

By John E. Borland, Mus.B.

Definition of Subject.

It is desirable to preface the following paper with a definition of its scope. Negatively stated, it has no concern with *standards* of pitch, such as the Diapason Normal, the new or the older English Philharmonic pitch, the Society of Arts pitch, the Scientific pitch (C 512) or the many unauthorised varieties, ranging from two or three semitones below any of these standards — to be found in suburban and country places where the rounds of the pianoforte tuner are as rare as angels' visits—to the extreme military pitch which is a semitone higher than the present orchestral pitch. We shall assume that there is but one existing standard, and this is equivalent to saying that, for the sake of argument, we shall endeavour mentally to realise a musical millennium.

Stated affirmatively, this paper will draw attention to two aspects of the pitch question which are of vital importance to music-lovers who desire to form a clear conception of the real height or depth of musical sounds, whether presented to the eye in musical notation or to the ear in actual tone. We must try to keep distinct these two aspects of the subject, though a little overlapping is inevitable because at least some of the mistakes of the ear are due in the first instance to the deception of the eye.

Limits of time, it should be added, make necessary the use of a somewhat dogmatic method of stating conclusions which have in all cases been arrived at after full consideration of proved facts.

(A) VISUAL MISCONCEPTIONS.

The stave-notation which has been in use, with modifications, for about five centuries, is commonly spoken of with pride as a pictorial representation of musical sounds. In a sense, this is true; but the picture which the unaided notation now offers to us is far from complete, and the power to read intelligently a full orchestral score, much more to write one, postulates the possession of a perfect memory, a wide knowledge of musical history, and an intimate acquaintance with the uses of many instruments. A simple vocal score is not without its pitfalls, and even the two pianoforte-staves present anomalies in extreme keys, and in chromatic music, with which we could well dispense.

Musicians have a great affection for the notation which has served for the recording of the masterpieces of the past, and it is extremely difficult to put one's self, as it were, outside one's life-work, and to criticise calmly and dispassionately so venerable an institution as the stave-notation. But when once this step has been taken, it is impossible to remain blind to the fact that, however well the fundamental principle of the notation may have suited the simple, diatonic vocal music of Palestrina, it had already become somewhat of a hindrance to the art by the time of Bach, still more so for Beethoven, and a perfect mass of incongruity and ambiguity in the hands of Richard Strauss.

The Clef System.

This was designed to present varying groups of lines and spaces fit for simple vocal music, which was short in compass and sedate in movement. By altering the positions of clefs, C or any other note was made to appear in any position; and so long as music remained simple this offered little inconvenience to the eye. But with the growing complexity of musical design the full use of the clef system became impossible, and at the present time only two forms of clef are in common use for voices, viz., the G clef on the second line, and the F clef on the fourth. The diagram A (p. 351) shews some of the various ways in which "Middle C" has been written for voices.

Modern composers have already admitted tacitly the inconvenience of this variable system, and the result is the virtual disappearance of the C clef from vocal scores. The Alto part can be fairly well accommodated on the lower ranges of the Treble stave, but the

Tenor part offers a serious difficulty. It is too high, usually, for the Bass stave, too low for the Treble, while the use of its own C clef has been abandoned by common consent of singers, composers, and publishers*. The result is that the Treble clef is now used for Tenor parts, with the notes written an octave higher than they sound. Sometimes the printer records this fact at the beginning of a piece, but if an intermediate page is opened there is nothing to show which is the Tenor stave, or which of the Treble clefs is to be read literally, and which an octave lower. Mr. McGranahan, the compiler of a book of Revivalist hymns for male voices, uses a C clef in the third space for his Tenors, thus making the stave correspond, as to the names of notes, with the Treble stave. This seems a sensible arrangement; anyone who knows the Treble clef can read from it, while the correct octave is indicated by the form of the clef. But purists would have none of it. Though C had been placed on every line of the stave, the clef had never been seen in a space before, therefore it must not be. So we use a Treble clef instead, which indicates sounds an octave higher, and think we are valiant defenders of historic accuracy. Mr. Otto Goldschmidt, in the "Bach Choir Magazine," introduced a double Treble clef for Tenor voices, but his example has not been much followed.

* This change dates from the time when choral singing passed into the hands of *amateur* vocalists. The Tonic Solfa Notation was another outcome of the Victorian era—another amateur protest against complexity.

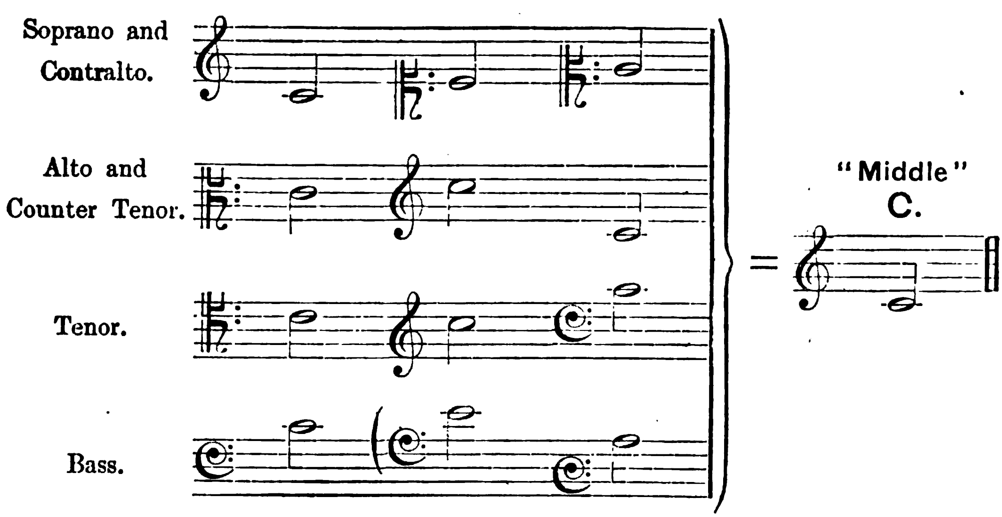
The Alto voices, as already mentioned, can be accommodated on the Treble stave at their accurate pitch, but this has not invariably been done. Old oratorio scores, published during the transition stage when the C clefs for voices were passing out of use, give the Alto part on a Treble stave an octave higher than the real sounds, and a good deal of male-voice part-music followed the same undesirable custom.

Assuming that it is the desire of musicians to make their art of the greatest possible service to the race, it is easy to see many ways in which its notation could be greatly simplified, and a reform of the clef system is one of them. Of course, to such as love mystery and confusion for their own sakes, it is useless to appeal; and it is equally futile to address those to whom Professionalism stands before Art. The latter class is interested in making the doors of Art hard to open, like members of another profession who are said to make a farthing's worth of cinnamon and water become chargeable at half-a-crown by writing the prescription in abbreviated dog-Latin and illegible calligraphy.

Looking at the matter with an open mind, is there any reason beyond tradition why all staves should not have C in the same position?

The middle line would be a good place for C (as the present Alto clef). This arrangement would give us an extra note upward for Trebles, and an extra note downward for Basses, and the middle stave would serve

DIAGRAM A.—VOICES.



equally well for Tenor and Alto voices. The clefs would then show merely the octave in use, and it would be better still to discard the fancy signs altogether and use numerals so that the series could be extended upwards indefinitely.

TRANSPOSING INSTRUMENTS.

The inconsistency and irregularity of our Notation, as used for instruments, put entirely into the shade the troubles of the vocal score. "Transposing-instruments," it may be desirable to explain for the benefit of those to whom an orchestral score is unfamiliar, are instruments which give sounds quite different from those noted down. The simplest form of transposition is that of an octave, and has arisen mainly because of the limited compass of the three clefs (which were originally designed for vocal music), as compared with the wider range of the orchestra, from the low E or D of the double-bass in the 16 ft. octave, to the top notes of the piccolo, which reach the upper extreme of the pianoforte keyboard. The double-bass occupies most of its time in producing sounds which are below the ordinary bass-stave, while the piccolo would find only three or four of its notes on the treble stave if the actual sounds were written. Hence the custom has arisen of writing the bass part an octave higher, and the piccolo part an octave lower, to the confusion of many a budding composer, who, though he knows these facts in the back of his mind, is not always practically conscious of them, as his scores indicate.

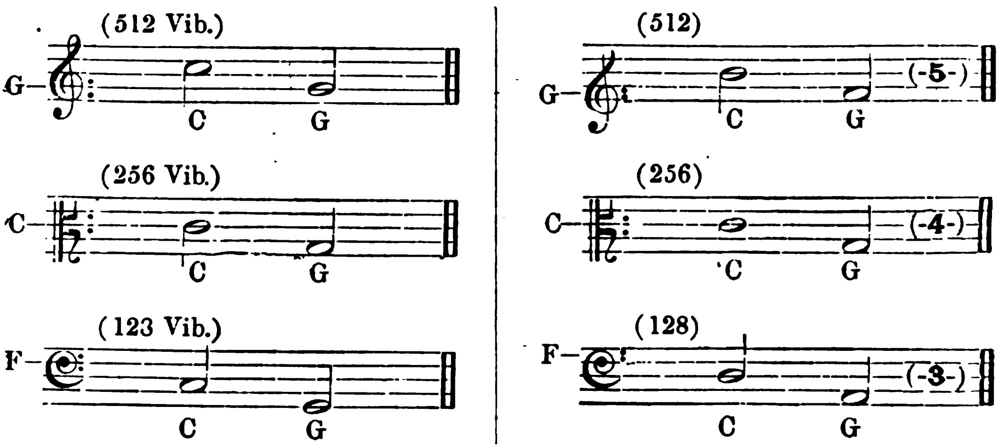
But this octave-transposition, due to the lack of expansiveness of our clef system, is as nothing compared with the chaos of other transposing-intervals which the orchestral developments of the last two centuries have brought about. Under this system a given note on paper may sound at any pitch within about two octaves and a half. Could anything be more subversive of a clear conception of musical pitch on the part of composers, players or listeners? The three following diagrams show something of the state of affairs. (See Diagrams C, D, and E.)

How has this confusion come about? The octave intervals included in these diagrams are mainly due, as before shown, to the limitations of the clefs. The other intervals (seconds, thirds, and so on, in addition to the octave in some cases) are due to former imperfections of mechanism on the instruments themselves. From the seventeenth century until early in the nineteenth, the wind instruments could only produce with difficulty anything beyond a diatonic scale in two or three keys, and the trumpets and horns could not do even that. If any proof be needed to show that this kind of transposing is wholly due to former incompleteness of mechanism and has no more rational basis, it may be found in the history of the slide-trombone, which, possessing a complete chromatic scale from an early epoch, has always had its real sounds indicated.

So long as the transposing instruments in the orchestra were few in number and their music was simple, the inconvenience was but slightly felt. But although instrument

DIAGRAM B.

PRESENT USE OF THREE CLEFS. A POSSIBLE SIMPLIFICATION.



makers have now removed the original reason for transposing, and composers are now writing parts of increasing complexity and number, the old system is maintained, without rhyme or reason except custom, the fear of criticism, and possibly the sort of laziness that will sometimes blunder on with an untidy workshop, or writing desk or music cupboard, rather than tackle the problem of putting things straight. We again hesitate to suggest a fourth cause, *i.e.*, deliberate intention to keep the art of music in the hands of a close corporation. Antiquarianism is all very well when kept to its proper sphere, viz., the *study* of past things, but it is a nuisance when it endeavours to compel us to do twentieth century work with the tools of the seventeenth century.

[Quotations from the scores of Haydn, Berlioz, Brahms, Mackenzie, and Richard Strauss, were at this point brought forward to illustrate the growth of the present confusion.]

Is there *anything* to be said in favour of the maintenance of the transposing system? We reply without hesitation in the negative—with a possible mental reserve in the case of the clarinet family. Owing to some mechanical difficulties which have not yet been fully overcome, it may be desirable for a few years to maintain the use of clarinets (of each compass) in two keys (not more); but this must be looked upon as a temporary expedient, a concession to their imperfection, which time and the makers' skill may be trusted soon to remove. Speaking broadly, the whole transposing system could be swept away to-morrow if composers and publishers would but undertake the task, and the gain to the art would be enormous. There is commonly said to be a serious technical difficulty for players who have to use several instruments of different pitch, if the actual sounds are shewn in their copies; but this is much exaggerated. Flute players (on the modern concert flute) play quite well the rare passages written by Spohr and others for the flute in F, or E flat. Clarinet-players voluntarily discard the C clarinet, and sometimes the A clarinet, and play everything on their favourite B flat instrument rather than change it. Trombonists read and play actual pitch without difficulty on instruments pitched in E flat, B flat, and G respectively. Horn and trumpet players, having now complete chromatic scales at their disposal, read any part and reproduce it on any of their numerous crooks which they may prefer. The Euphonium and the Bass Tuba (of the "Sax" tribe) use actual pitch, and

DIAGRAM C.—INSTRUMENTS OF HIGH PITCH.

players find no difficulty in changing to other members of the same family of instruments; while a last illustration may bring the point home to a larger number of hearers, viz., violinists do not look for a part transposed a fifth higher, and try to imagine they are still playing a violin, when they take up a viola.

With one word more, we pass from this part of the subject. The confusion in the orchestra is bad enough, but in a brass band it becomes positively laughable. In some bands not a single instrument gives the sounds indicated in the parts. The Treble clef alone is used, even for the bass instruments, and everybody transposes besides. Could anything be more stupid? The result is that many a bandsman never acquires any sense of absolute pitch. He has a hazy ideal in his mind, known as "concert" pitch; but it is an abstraction, outside of his daily experience.

Equal Temperament.

Musicians speak with warmth of the achievement of J. S. Bach in the establishment for ever of equal temperament, or the division of the octave into twelve equal semitones, as the basis of music. But Bach has been dead 155 years, and we still stumble on with a notation which is incapable of showing the real facts of music in this respect. Bach, Beethoven, Schubert, Spohr, Weber, Schumann, Mendelssohn, Brahms, Grieg, Wagner, Strauss, and a host of others* have declared in unmistakable terms that C sharp and D flat are the same sound, A sharp and B flat, F sharp and G flat, and so forth, but they have no means of showing it to the eye, and theorists have filled many books with explanations of the supposed differences between these pairs of notes. The subject is too vast for the present occasion, and I can only refer briefly to it and to an admirable attempt which has been made to remove the difficulty, viz., by Mr. W. H. Thelwall in his semitonic notation. There are many musicians who refuse even to consider any radical reform of the existing notation, and to such it is useless to speak. They look upon it almost as an inspired thing, or at least as an historic growth, to be preserved with veneration and awe. This attitude would invite more respect if it did not form such a bar to progress, and if it were more in conformity with the procedure of artists and scientists in other walks of life. The vital question is, are we to maintain at all costs a form of notation which no longer represents the facts of music, because it once did so? Should a gardener leave dead or non-productive branches on an apple-tree because they once bore fruit?

There can be no doubt that primarily our notation was intended for purely diatonic music. For this it was well fitted; but it is only poorly adapted to record modern developments since Bach's time. F sharp and G flat are not essentially connected with either F or G; they are separate sounds, or in equal temperament one separate sound, owning no allegiance to either F or G. The lack of prophetic foresight on the part of seventeenth century musicians with regard to possible developments is indicated by an extract from Playford's "Introduction to the Skill of Music" (1654). After describing the ordinary keys, with few sharps or flats, he says: "There may be more thought on to puzzle young beginners, but not of any use, here being variety enough to please the ear." Later, speaking of clefs as well as keys, he says: "I would advise you at the first to get

---

* Some Authorities, on Equal Temperament.

"It is certain, evident, indisputable, that the 21 signs of the enharmonic scale contain really nothing more nor less than the 12 degrees of the chromatic scale . . . . D flat is neither flatter nor sharper than C sharp; these notes have the same meaning, they express the same sound. Sameness of meaning for different signs—that is, enharmonic equivalence—is the source of all the wealth in modern art. Suppress the tempered system, suppress enharmonic equivalence, the sameness of meaning for different signs, and by the same act you suppress the most beautiful inspirations of composers, you suppress music itself."—(Report of Conference of French experts, including Auber, Halévy, Berlioz, Gounod, and Ambroise Thomas; quoted by Helmholtz.)

"In all cases the scale is an artificial product contrived for particular artistic ends. The old scale, with a limited number of available notes, was sufficient for the purposes of the old church music, because the aims of the art were different. The growth of modern music brought new aims into men's minds, and they had to contrive a new scale system to satisfy them. The division of the octave into twelve equal intervals, to which Bach gave his full sanction, is now a commonplace of every musical person's experience."—(Sir Hubert Parry, "The Art of Music," p. 188.)

"An ideally-tuned scale is as much of a dream as the philosopher's stone, and no one who clearly understands the meaning of art wants it."—(Ibid., p. 46.)

"This duodecimal division of the octave (equal temperament) was known to the Greeks, but its modern revival, which dates from about the sixteenth century, has been one of the happiest and most ingenious simplifications ever known in the history of music, and has had the effect of advancing the art to an incalculable extent."—Dr. W. Pole, Grove's "Dict. of Music and Musicians," article, "Scale.")

"The greatest amount of patience and perseverance must be expended on section IV. (part II.), in which the foundation should be laid of pure intonation . . . . Let it be remarked that by pure intonation is meant that which is according to equal temperament; for modern music no other exists."—(Spohr, Preface to the "Violin School," Eng. trans.)

any song you meet with put into one of the Natural Keys; also I would have you make use of the Treble Cliff, being always placed on the second line from the bottom of your five; the Bass Cliff is not so common as that, although it's as certain as the other; but the Tenor Cliff is very uncertain, for you may find it placed upon every line of the five, except the uppermost."

representing music itself, in its broadest and most scientific aspects. Modern music, which becomes impossible without equal temperament, is here represented exactly as its composers conceive it. Not only are the supposed differences between F sharp and G flat and similar pairs of notes ignored, as all composers since Bach have ignored them, but all the confusion of clefs is abolished, so that a given

DIAGRAM D.—INSTRUMENTS OF MEDIUM PITCH.

In presenting before you two diagrams of Mr. Thelwall's "Note for Note Notation" (pp. 357-8), I would draw careful attention to one point; it is not especially adapted for any one instrument, like some other attempts have been (based, in fact, upon the pianoforte keyboard, a thing which is itself of a fortuitous and unscientific origin), nor for voices, like the Tonic Solfa; but this notation aims at note in each octave appears in the same stave-position, while the octaves are indicated by figures.

In Diagram F we see the scale of G in its semitonic major and two minor forms. No sharps or flats are required as a "signature," because actual pitch is indicated by the notation without any such qualifying signs. Whole tones proceed from space to space or

line to line, semitones from line to space or space to line.

Diagram G shows the emancipation of the so-called extreme keys under this system. There is no valid reason why the keys of F sharp or C sharp should be penalised as they are by the established notation. It ought to be as easy to read and to play in these keys as in the so-called natural key of C, but owing detract from the merit of his invention. Its universal employment would save a large amount of the time which it is now necessary to devote to the overcoming of the mere notational difficulties with beginners. Amateur musical opinion is quite capable of carrying this new thing to a successful issue even in the face of professional opposition, if its advantages are once appreciated.

DIAGRAM E.—INSTRUMENTS OF LOW PITCH.

to imperfections of notation and of instruments this is far from being the case. Mr. Thelwall has removed the difficulty from the notation, and is to be congratulated upon the scientific attitude he has adopted towards musical theory and upon his method of applying his deductions in his notation. There are enormous obstacles in the way of its adoption, chief of which stands vested interest, but this does not

(B) AURAL MISCONCEPTIONS.

In this second part of our subject, which deals with misconceptions of pitch, due to natural defects or imperfect training of our ears, it is impossible to speak quite so strongly as in the former part, because here the personal equation has to be reckoned with. We do not all hear the same sounds in the

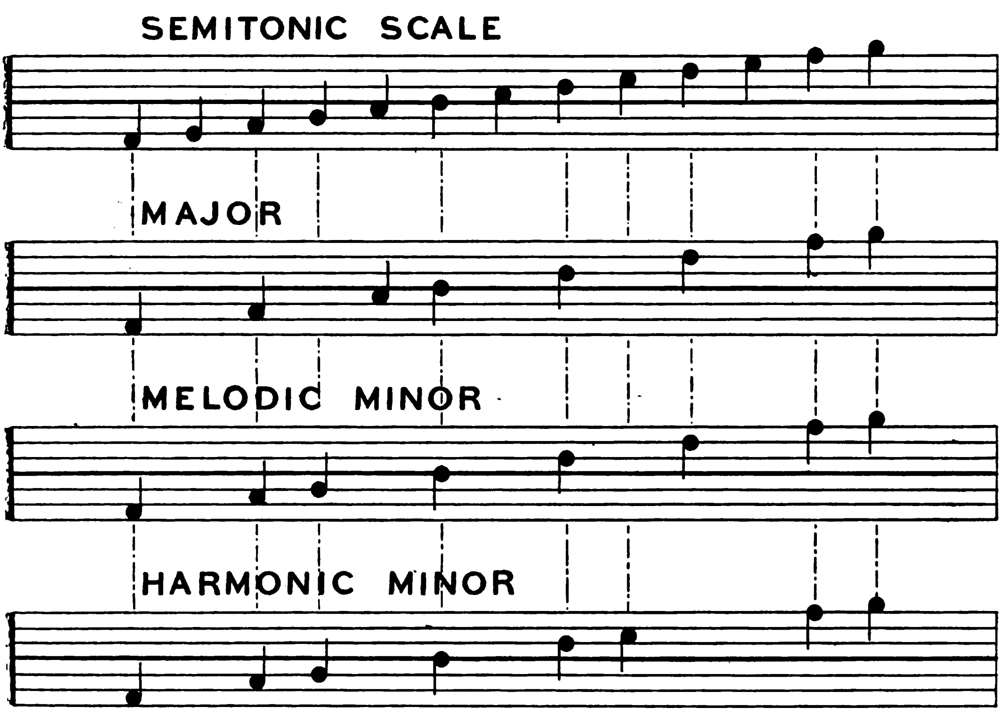
same way. Some ears are keen, others dull; others again are long, in the proverbial sense, so that their possessors never appreciate what they may actually be hearing.

Misconceptions are also due to external circumstances. Our power of estimating the actual height or depth of a sound is frequently discounted by the proximity of other sounds which are higher or deeper. For example, the low C of a violoncello seems quite a fine deep bass note in a string quartet; in company with the double bass or with organ pedals it seems a very ordinary tone, not particularly full, and not very deep. The resonance, or otherwise, of buildings has also much effect upon our hearing of sounds.

Scientifically stated, height or depth of pitch depends upon the number of vibrations in a given time. Thus, middle C is said to have 256 vibrations in a second, treble C 512, and so forth. But in practice we seldom hear a pure and simple musical tone, even the simplest of the ordinary sounds being combinations of many overtones with the prime sound. The extreme harshness of some dissonances in modern choral music is largely due to this cause. The result is that the ear often judges a bright tone to be higher in pitch than it really is, owing to the presence in considerable strength of its upper octave and other harmonics. By the kindness of Messrs. J. W. Walker and Sons, whose organs are famous for their varied and delicate tone-quality, I am enabled to demonstrate this with some organ pipes. These, and other experiments, I present with the full consciousness that they may not be convincing to all listeners equally, owing to differences of ear. We have before us a pipe sounding Tenor C, of a dull fluty tone. This gives us an impression of depth which is quite absent from another pipe, of the Gamba class, of which the fundamental sound is the same. This reedy tone suggests to the ear that at least some other sounds are present with the fundamental, and this is indeed the case. In extreme instances it is possible to make a tone

DIAGRAM F.

THELWALL'S NOTE FOR NOTE NOTATION



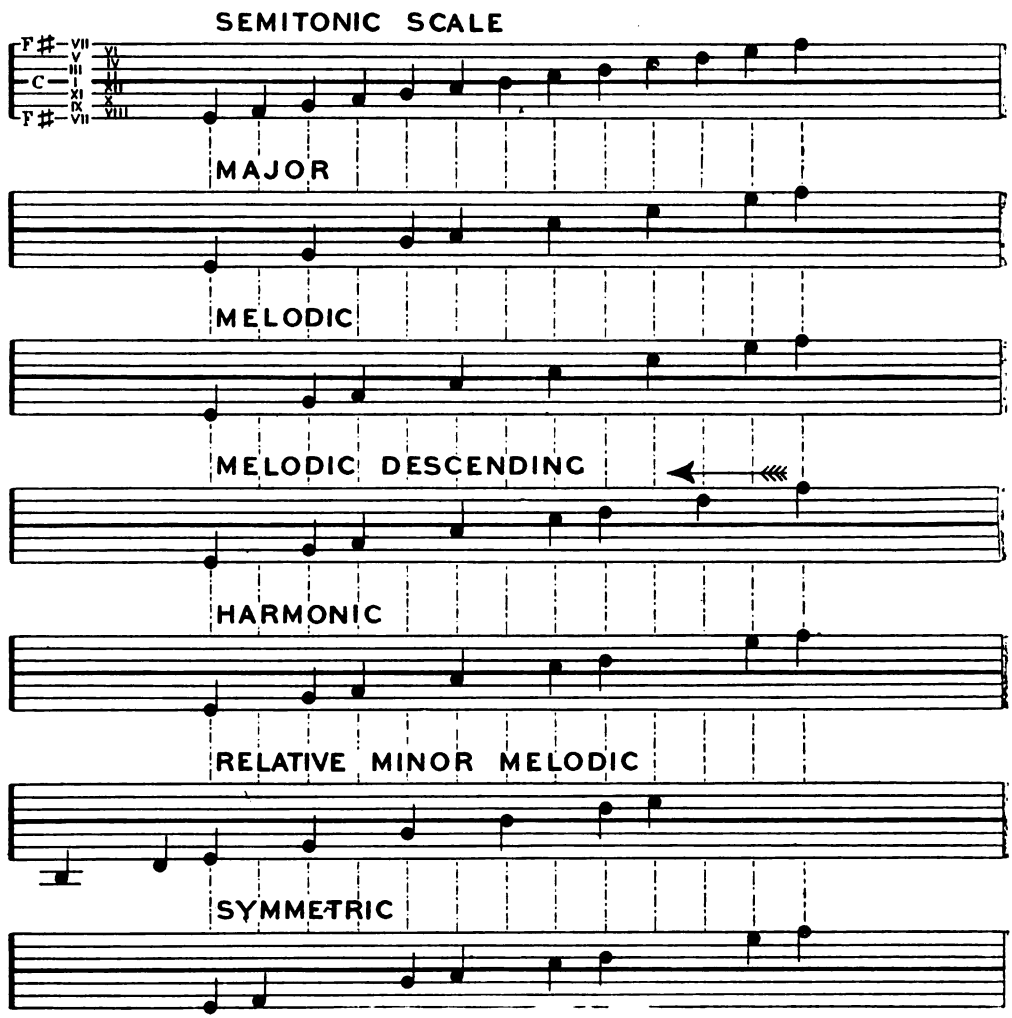
so reedy that the fundamental sound seems to have disappeared altogether or can only be heard with effort. An interesting experiment can be made by adding smaller and higher tones in proper proportions to a fluty fundamental sound, and obtaining by the combination an effect which is identical with that produced by the single pipe of bright reedy tone.

In addition to the difficulty of judging pitch which is caused by the presence or absence of harmonics, our ears are limited in their ability to distinguish extremely high or extremely low sounds. Of this also Messrs. Walker have kindly provided two illustrations. In the one case a large organ-pipe of soft tone can be used as a basis for an extemporisation in almost any key. In some keys it may sound not quite satisfactory as a tonic pedal, but the average ear is incapable of saying what is wrong. In the other case an extremely small pipe, which goes almost beyond the range of useful musical tones, can practise a similar deception. Many experiments of this kind can be made conveniently upon a pianoforte: even when the extreme treble and bass strings are accurately tuned and give good tone it is very difficult to judge the actual pitch.

There is a good deal of misconception as to

DIAGRAM G.

THELWALL'S NOTE FOR NOTE NOTATION



the real pitch of voices, owing mainly to differences of quality. There is a small but very persistent group of vocal trainers that is firmly convinced that the adult male voice covers the same range as the female and not the octave below. One lecturer recently undertook to sing the high soprano C; after painfully climbing up the scale through the tenor octave he reached the high tenor C, and stopped. The audience called on him to finish his task but he said he had already done so, and nothing would convince him that he was not really giving the C of 1024 vibrations. He was no doubt deceived partly by the inaccurate, conventional notation, and partly by the overtones of a tenor voice in its bright top octave. A well-known concert vocalist who fills important engagements to-day labours under the same delusion; and another tenor known to myself has such a peculiarly brilliant top A that it is difficult for a listener to believe sometimes that there is not a treble-voice sounding the upper octave at the same time. The effect of bright reedy tone can be tested with choir-boys. If the choirmaster sing the C of 256 vibrations with his ordinary full voice and asks them to give the same sound they will almost invariably sound the octave above; but if he hum the same note very softly on the vowel "oo," they will most probably pitch upon the proper octave.

Hazy conceptions of pitch obtain currency in many other connections. Few people are aware how high a boy whistles. The pitch of large bells is usually thought to be lower than the reality, while, on the contrary, there are bells of bad tuning which give the impression of being higher than their true pitch. Mr. W. W. Starmer, who has devoted much time to the subject of bells, kindly furnishes some measurements and weights of well-known bells, with their accurate pitches. After stating that a bell weighing as much as two tons, if made on the most satisfactory proportions, will produce a sound no lower than middle C, Mr. Starmer quotes the following particulars of existing bells:—

Famous bell of Erfurt, diameter, 8 ft. 4 in.; weight, 15 tons 15 cwt.; note, tenor E. Lavenham bell, diameter, 4 ft. 4½ in.; weight, 24 cwt.; note, middle D. Beverley bell, diameter, 5 ft. 1 in.; weight, 41½ cwt.; note, middle C. St. Saviour's, Southwark, diameter, 5 ft. 6 in.; weight, 52 cwt.; note, middle B flat. Big Ben, diameter, 9 ft.; weight, 13 tons 11 cwt.; note, about tenor E. It has probably astonished many listeners to hear that such large bells have so comparatively high pitches.

The orchestral timpani have also been misjudged as to pitch. These drums, as all musicians know, give definite notes, unlike the bass drum, which only makes an earth-shaking noise. But a good many listeners are of opinion that the kettledrums sound an octave lower than they really do.

Amongst the wind-instruments there are some which are deceptive by reason of their brightness, others on account of their dullness of tone. In the former category we find most of the brass, while on the other hand some of the large-bore brass instruments, when played softly, give an impression of depth even beyond that which they undoubtedly possess. It is not commonly realised that the tube-length of the French horn in F is the same as that of the mighty-toned bass-tuba. The volume of tone produced by the latter certainly gives cause to imagine its pitch to be different from that of the former even when they play exactly the same notes. The low notes of the clarinets, and especially of the tenor and bass varieties, also give a fine impression of depth beyond the actuality. If time permitted there is hardly a limit to the interesting comparisons of this kind which might be drawn, but I must refrain.

CONCLUSION.

I reserve to the last a brief appeal that if possible we may secure some tangible result from to-night's discussion on the first half of the paper. I have spoken strongly about the transposing instruments, because the matter is really one of the greatest importance in musical education. If I have not succeeded in convincing you of the feasibility as well as the desirability of abolishing the present system, or want of system, I must plead lack of time as the excuse. There is no lack of proofs ready to hand, if more are needed to back up my statements. Having been mixed up with orchestras and orchestral players from early boyhood, my convictions have been formed by practical experience, and are by no means the result of mere theorising. Dr. Saint-Saens and other composers are already making tentative experiments in the direction of treating some of the wind as non-transposers, but there is really no need for such caution, and this distinguished Society, as an impartial body, would perform a notable service if it could see its way to inaugurate a conference to discuss the situation. Without attempting at

once any radical change in the notation itself, an agreement to use the notation only in a rational and unambiguous manner would be an achievement for which musicians would owe to the Society of Arts a debt of the deepest gratitude.

DISCUSSION.

Mr. BLAIKLEY thought all that Mr. Borland had said with regard to the difficulties incidental to the customary way of writing for transposing instruments was perfectly true. But, as regards musicians clinging to the system from a desire to make the musical profession a close corporation, he felt that Mr. Borland was in error, and that the transposing system had come about through the desire to make music easy to the actual performer. It must be remembered that the thing the player wished his written part to show was not the particular pitch in the general scheme of the notes allotted to him, but signs for fingering, and by the transposing system he was relieved from the confusion of learning various sets of fingerings for the same written sign. There was a great deal to be said on both sides.. He noticed that Mr. Borland, in his remarks with respect to absolute pitch as it stood at the present day, said that the military pitch was a semitone above the present orchestral pitch. He understood, of course, that Mr. Borland referred to the philharmonic pitch of the year 1896, which roughly corresponded to the diapason normal. The present military pitch was certainly not a semitone above that. He was speaking, of course, of the authorised military or Kneller Hall pitch. That was about two-thirds of a semitone above the present concert pitch. That this pitch was often exceeded he must admit; but that excess was not authorised. There was no authorised pitch in this country above the Kneller Hall pitch. Mr. Borland, no doubt, knew all these things.

Mr. BORLAND said that he had the permission of the Chairman to reply to that point at once. There were many unauthorised varieties, but the word "unauthorised" was in the paper already. Of course, he was fully aware that the Kneller Hall pitch was not a full semitone above, but they were always going up.

Mr. F. W. FLETCHER said that he should like to support Mr. Borland's suggestion that the Society of Arts might very well arrange a conference both as regarded notation and the question of pitch. In the Exhibition of 1887 there were very many examples exhibited of various notations. With regard to the notation, one of the greatest difficulties appeared to him to be the change from a minor to a major key. If they were playing in B minor and they got a sudden change into B major that seemed to be as difficult in tonic solfa as in the ordinary notation; and in the tonic solfa they had the changes coming one after another, whereas they could overcome many of the difficulties in the old-fashioned notation. As regarded the illustrations that had been given he saw the same difficulty. There would be just the same difficulty in reading rapid changes of key in the new method as in the other. He should like Mr. Borland to explain how various changes of key in this notation were shown. As far as concerned orchestral notation, he thought that there might be a very great improvement in that. The paper had been very instructive, in giving them some idea of the difficulties which they must encounter in arranging a score.

Mr. W. H. THELWALL wished to thank Mr. Borland for the assistance and sympathy which he had given him in bringing forward his musical notation. Musicians were very conservative, and did not like the idea at all of any change of notation. With regard to the question of change of key he might illustrate what he had to say in this way. Of course in every key all the twelve notes of the octave were freely used by composers, and if they wished to give a definite idea of what the key was they must confine themselves for a bar or two to the notes of one of the diatonic scales. Of course, in the notation which had just been shown, each major scale had its own particular lines and spaces on the stave, and directly the performer found that those particular lines and spaces were prominent he knew what key he was in. But, beyond that, by an exceedingly simple device, the tonic for the time-being could be shown so that anyone could recognise it. As each line and each space represented a definite note of the octave, all that was necessary was to put a particular mark on the line or the space that happened to be the tonic for the time being. What he proposed was that a large square mark should be put upon the line or space which was the tonic when the composition was in the major mode. When the composition was in the minor mode he put a triangular mark. If the composition began in the key of F sharp, the mark would be put on the lowest line. If it then went into C sharp the mark would be put on the fourth space. Thus by this system they had, he believed, the advantage of both relative and absolute pitch being shown far more clearly than in any other system. He might refer to ledger lines. Lines which were apparently ledger lines occurred in his system, but they were really lines borrowed from the next stave; and the signification of the notes on the ledger lines was exactly the same as that of the notes on the stave. The particular stave intended would always be shown by putting

a figure on the middle line, the octave of which middle C was the centre. Then they could write for any instrument in the orchestra in its true position by simply putting the right figure for the octave. From his point of view the present system involved an enormous waste of time. The new method was so simple that the pupil might learn the way in which every note in music was represented in a couple of hours fairly well, or certainly in a very short time. He had only to learn the position of twelve notes and the meaning of the numbers of the octaves. In the old notation the pupil had to become absolutely familiar with four or five hundred different signs before he could read. He had found plenty of cases of notation which practically no musician could read. If those pieces were written on the new system they could be read with perfect ease. Of course the notation was a large subject, and the author could not deal fully with it in the time. It had been very carefully thought out, and had been submitted to a number of very eminent musicians, and the representation of equal temperament was considered by them perfectly satisfactory.

Mr. George Langley said that as a professional musician he should like to throw what little weight he could into the scale in favour of the change with regard to the simplification of scores. It was very confusing when there was a chord to have to look at the different keys of the transposing instruments to realise what were the actual notes. It might be argued that in many cases the notation for the transposing instruments might be necessary to the players themselves, but that was no reason really why the notation should be retained in the scores. Therefore, he would say that in that case they might have the actual notes as they sounded. With regard to the question of realising the twelve chromatic notes under the system, he did not quite go with Mr. Borland. Let them take one chord. Take the following notes, reading upwards: A flat, C, E flat, and G flat. That was a well-known chord of the dominant seventh. They would play in the key of D flat, and all at once they changed that enharmonic G flat to F sharp, which made a chord of the augmented sixth. They resolved it into the key of C minor, and the mental effect was quite changed. This showed that the F sharp and the G flat, although absolutely the same notes on the piano, were different notes in theory, and that was his contention. Although they had equal temperament they translated mentally every note. He had much enjoyed Mr. Borland's paper, and he hoped that the points which he made with regard to the score would be enthusiastically received.

Mr. T. R. Croger said that as the greater part of the paper was devoted to orchestral matters, he should like to refer to two or three points. The great offenders in the score, or the transposing instruments that gave so much trouble, were the clarinets. The flute, the piccolo, and the oboe were all right, for they were octave instruments. They sounded note above note in the octave, but the clarinet being a straight tube, instead of a parabola, gave twelfths. Therefore they did not get the octave rise, but a rise to the twelfth. This made it exceedingly difficult for clarinet players to play in keys which had a great number of flats and sharps, and that was why several instruments were used. If they could play always with a C clarinet, there would be no difficulty in transposition; but it was not satisfactory in notation to play many sharps or flats with an instrument with long keys. The consequence was that there were three of the instruments in the orchestra. The reason why they had to be changed was that, for some peculiar reason, the B flat was very much better to play upon, but if they had to play a lot of sharps it was difficult. If the strings were played in two sharps the B flat clarinet had to be played in four sharps with an awkward fingering. People wrote in the good old days, say, in the key of G, but now the player did not know where he was from bar to bar. He did not know the tonality of a work which was constantly changing, and the clarinet player was constantly picking up one instrument and putting it down and picking up another. If all the clarinets could be put in C, there would be no transposing. But the worst offenders were the horns. The trumpets were in a similar case, but not nearly so bad. The horn was originally a hunting horn, and they played a few open notes; but now the moderns treated it as a chromatic instrument with all the semitones in it. With regard to the clefs, he had a communication yesterday from a man in the north of England who belonged to a brass band, and he played an instrument which curled round his shoulder from the treble clef, and thousands of brass players did that. With regard to the organ pipe yonder, when Mr. Borland played the low C, he (Mr. Croger) failed to hear that note at all, but he heard F. If anybody could devise a means by which a horn could be rendered a non-transposing instrument, he would do more to settle the difficulties of the score than anything else.

The Chairman said that he was sure that they would all agree with him in thanking Mr. Borland for his excellent paper. Those who occasionally consulted a score knew how complicated it was, but probably none of them had had such a dreadful picture before them as Mr. Borland had held up to-night. Of course, notation was a great difficulty, especially to young musicians. There was a story of an eminent musician of modern times who was almost self-educated, and he conducted a band in his village, and then he was induced to write something for his band, which he did. But the result was horrible, for he did not know that the instruments transposed. This composer

was Dvorák! Of course it must be borne in mind, for the comfort of Mr. Thelwall, Mr. Borland, and many others, that the art of notation had been one gradual development, and it had gradually gone on till it had got to the present system, or what he might call the vernacular. Mr. Borland had said that there was probably a professional wish to keep the art close, but he (the Chairman) could not say that he agreed with that view, for the art of music had a much simpler notation now than it had many years ago. Probably notation was still in a state of development, and they might live to see Mr. Thelwall's method adopted. The great difficulty was that there was a large amount of music which had something more than antiquarian interest, which would be shut away from people in a generation or two if the existing notation was abolished altogether. To follow this music people would have to learn, in fact, two languages. Then there was the question of the expense of bringing out works in the new notation. He had the pleasure of a long interview, a few weeks ago, with Mr. Thelwall, who was good enough to explain his system, and he made a very ingenious remark. He said that the pianola was getting very common, and it answered the purpose of a musical instrument maker to make copies of all the standard works for the pianola. No doubt, directly they got into the new notation, Beethoven's symphonies would be published in it. As to transposing instruments, they did not number their staves as Mr. Thelwall would do, but it was perfectly understood what pitch a piccolo, for instance, was playing in.

The vote of thanks having been carried unanimously,

Mr. BORLAND, n reply, said that what had been said about the clarinet was also in his paper. It was for makers to devise some system whereby a clarinet would play in any key in the same way as an oboe. In fact, a few accomplished players played everything on the B flat, that in C being hardly seen in the orchestra now. The A natural instrument was also disappearing. He fully realised that for less accomplished players the transposing system was desirable; but still it need not be kept in the scores. The question of the pitch of Kneller Hall he had already mentioned. Mr. Langley had referred to the augmented sixth and the dominant seventh. The difference was no more than the difference between D in the key of D, and D in the key of G. They were totally different things. We called them D simply because that special note had not usually any other name. With regard to musicians keeping music a close corporation, he knew, of course, that in a general way it wes not so, bat there was a little of it sometimes. He heard a distinguished man say that he thought it a good thing to have some stumbling blocks to keep dabblers out. On the other hand there was so much difficulty in the real music itself, after they had got past notation, that they did not need to invent other difficulties to make the subject still more difficult than it would naturally be. That would be like building a high wall round Charing-cross Station, so that they could judge of the earnestness of travellers by requiring them to climb over the wall. Sufficient difficulties already existed. He was sorry to differ from Mr. Croger, but he thought that the horn was not the difficulty. The clarinet was the real difficulty in the score. The horn having a chromatic scale and very simple mechanism, there was no need that it should be treated as a transposer. As to the reference which Mr. Matthew had made to the music now existing and the new notation, it was certain that, if there was a demand for the existing music the publishers would print it in the new system. The question was whether the new notation was all that was desired, or would do all that was wanted. That could be only judged by practical experience. It must have the test of time, the same as everything else.

DISTRIBUTION OF THE WORLD'S INDUSTRIAL POPULATION.

Quite apart from their value in relation to the fiscal question, the Blue-books numbered Cd. 1761 of 1903 and Cd. 2331 of 1904, are of considerable value as affording to the student of industrial questions a compilation of information on various subjects. The sociologist will in the pages of the second book find much that is of interest concerning the consumption and cost of food in workmen's families in the United Kingdom, course of house rents, cost of clothing, fuel and lighting, and so forth, and an examination of the fluctuations in employment recorded will interest both employers and employed. The course of pauperism in some of the chief commercial countries and its relation to emigration are also important subjects which are dealt with. Of wide general interest is the section devoted to the distribution of population engaged in the principal industries throughout the chief countries of the world. The notes and tables given throw a useful light on the industrial composition of the populations of various countries, and on recent changes in such compositions. It must not, of course, be assumed that the distribution of output corresponds accurately to the distribution of producers, because of the differing productive value of the artisan in different countries; for instance, the Lancashire cotton operative is a very different unit as regards output from the cotton operative in a backward country like Russia, or the negro operative in the factories springing up in the cotton growing districts of the United States. It must also be borne in mind that a unit of population does not represent a constant unit of output over a period of

years. With improvements in mechanical devices, and their extension into common use, the output per head of population is continually increasing, though more rapidly in progressive than in unprogressive countries, and more rapidly in some groups of trades than in others.

Taking the industries in the order given in the Tables, and collecting for each industry the numbers of people engaged, we get the following figures for the principal countries, the year given in brackets being that of the latest year of computation :—

Cotton Industry.

	No. of Operatives.
United Kingdom (1901)	606,200
Russia (1897)	360,928
German Empire (1895)	254,546
France (1896)	186,900
Italy (1901)	171,126
United States (1900)	331,473
British India (1903)	178,444

In regard to the United Kingdom, there has been a decrease of 17,400 since 1891, Russia shows an increase of over 108,000 since the 1887 census, Germany an increase of 44,000 since 1882, France a decrease of 90,000 since 1866, and the United States an increase of nearly 95,000 since 1890. In regard to British India, the increase has been over 57,000 during the last ten years. In all these countries, including those in which the number of operatives has declined, there has been a continuous increase in the consumption of raw cotton.

Woollen and Worsted Industry.

United Kingdom (1901)	252,400
Russia (1897)	150,620
German Empire (1895)	262,260
France (1896)	213,900
Italy (1901)	79,391
United States (1900)	135,185

The figures for the United Kingdom again show a decrease since 1891 (its amount is 51,300 persons), while Russia, Germany, and the United States again show increases during the period intervening between the last census and its predecessor.

Flax and Linen Industry.

United Kingdom (1901)	108,700
Russia (1897)	52,560
German Empire (1895)	105,716
France (1896)	127,200
United States (1900)	3,411

A numerical decline in the case of the United Kingdom again occurs; the Russian figures show an increase, the French are stationary, while the German figures show a decline greater than the British.

Silk Industry.—So far as silk is concerned, the British and German figures show a decline, the Swiss and American an increase, while French figures are stationary. Very little value should be placed upon the French returns, as owing to the length of the period between the censuses quoted, important intervening fluctuations are probably omitted. The latest returns as to the number of workpeople engaged in the silk industry, are as follows :—

United Kingdom (1901)	40,490
Russia (1897)	38,229
Germany (1895)	69,801
France (1896)	159,500
Italy (1901)	184,164
Switzerland (1901)	33,506
Austria (1900)	23,602
United States (1900)	72,438

In regard to all these textile industries, the figures would have been of greater comparative value had it been possible to compute the average consumption of raw material per worker.

Mining Industry.—As regards the occupation afforded by the mining of coal and metals, the returns are considerably fuller than those given relative to the textile industries. In many cases the figures are given for several years. In the following table the numbers given are generally more up to date than in the previous Table, the latest year of computation being cited in each case :—

United Kingdom (1903)	871,889
Russia (1900)	376,541
German Empire (1902)	608,872
Belgium (1902)	135,749
France (1902)	180,658
Spain (1902)	87,508
Italy (1902)	63,270
Austria (1902)	157,322
Hungary (1902)	73,713
United States (1902)	518,197

In all these countries there have been marked increases. Taking in each case the last ten years, the increases have been as follows :—United Kingdom 133,000, Russia 173,000, Germany 186,000, Belgium 15,000, France 34,000, Spain 32,000, Italy 3,000, Austria 25,000, Hungary 18,000, and the United Stases 176,000.

Iron and Steel and Manufactures thereof.—In this case we have to fall back upon figures collected from miscellaneous reports in place of yearly returns :—

United Kingdom (1901)	1,248,940
Russia (1897)	432,497
Sweden (1901)	59,705
German Empire (1895)	1,114,509
Belgium (1901)	22,919
France (1896)	573,058
Italy (1901)	100,613
Austria (1900)	369,595
Hungary (1898)	75,942
United States (1900)	1,149,762

The only countries challenging the British lead in this section are Germany and the United States, both of whom have much larger populations. The increases in the chief of the above mentioned countries have been as follows:—United Kingdom, 267,000, since 1891; Russia, 168,000, since 1887; Germany, 307,000, since 1882; Austria, 86,000, since 1890; and the United States, 354,000, since 1890. This section, in its minutiæ, deserves special study by those interested in engineering industries generally. Not only are the numbers employed in specific branches of the industry given in most cases, but also their apportionment between different states or difficulties. In the case of the United States 34, in France 82, in Germany 12, and in the United Kingdom 18 sub-divisions are providing. Their contrasting in the pages of the *Journal* is, we fear, impossible (even were space available), on account of the different scopes of the various classifications. The figures already quoted suffice to shew the importance of the engineering industries to Great Britain, especially when it is borne in mind that the only two countries in which over a million citizens are so employed, contain vastly larger populations.

Leather Trades.—Under this heading are included saddlery, boot, shoe, and glove making. The following are the figures of the leading countries:—

United Kingdom (1901)	384,096
Russia (1897)	36,990
Holland (1899)	39,638
German Empire (1895)	555,438
France (1896)	322,900
United States (1900)	328,613
Italy (1901)	407,490
Austria (1900)	237,610
Australasia (1902)	17,709

The following are the chief gains and losses in the numbers of artisans employed. United Kingdom, loss of 22,000 since 1891; Russia, increase of 15,000 since 1887; Germany, increase of 13,000 since 1895; United States, increase of 47,000 since 1890; and Austria, decrease of 15,000 since 1890.

Paper Trades.—The heading includes paper manufacturers, stainers, envelope makers, paper-bag makers. The following are the chief figures:—

United Kingdom (1901)	74,150
Russia (1897)	46,190
Germany (1895)	85,104
France (1896)	51,600
United States (1900)	72,159

In this industry the British figures include an increase of 16,000; Russia, an increase of 27,000; Germany, an increase of 27,000; and the United States an increase of 31,000. In each case the increase stated is that which has happened since the preceding censuses, the dates of which have been several times recited.

Glass Industry.—The following are the principal figures:—

United Kingdom (1901)	32,929
Russia (1897)	37,543
Germany (1895)	58,221
Belgium (1900)	22,780
France (1896)	38,500
Austria (1900)	43,069
United States (1900)	61,164

The comparative gain or loss since the previous enumerations has been as follows:—United Kingdom, 4,000 increase; Russia, 16,000 increase; Germany, 20,000 increase; Belgium, 2,000 increase; Austria, 3,000 increase; United States, 11,000 increase.

Brick, Tile, and Pottery Industries—The comparative figures are as follows:—

United Kingdom (1901)	135,618
Russia (1897)	88,178
Germany (1895)	306,919
France (1896)	80,100
United States (1900)	122,227

There have been the following increases since the previous collecting of figures:—United Kingdom, 26,000; Russia, 49,000; and Germany, 80,000; in the United States there has been a decline of 9,000.

Chemical Trades.—The following are the figures of the leading chemical manufacturing countries:—

United Kingdom (1901)	58,232
Russia (1897)	33,148
Germany (1895)	97,470
France (1896)	42,900
Italy (1901)	15,958
United States (1900)	140,515

In none of the above-named countries has there been any decline in the number of artisans employed in the chemical industries. The increase in the United Kingdom has been 17,000; in Russia, 12,000; in Germany, 40,000; and in the United States 62,000.

Agriculture.—No detailed Tables are given in this respect, but in regard to the United Kingdom, Germany, and the United States the following estimated figures are given:—

	Number of Persons.	Number per 10,000 of population.
United Kingdom—		
1901	2,054,000	495
1891	2,266,000	601
1881	2,479,000	711
Germany—		
1895	8,045,000	1,554
1882	8,064,000	1,783
1875	not stated	not stated
United States—		
1900	10,187,000	1,348
1890	8,380,000	1,338
1886	not stated	not stated

The above Table shows that the proportion which the agricultural population bears to that of the entire country is three times greater in Germany, and two and three-quarter times greater in the United States, than is the case in Great Britain and Ireland.

Summary of Preceding Specified Manufacturing Industries.—From the summary Tables given on

pages 436-438 of the Blue-book, the following totals have been compiled, giving the estimated populations engaged in these industries at three different dates:—

	Number of persons.	Number per 10.000 of population.
United Kingdom—		
1901	4,914,000	1,185
1891	4,249,000	1,126
1881	3,866,000	1,109
Germany—		
1895	4,694,000	907
1882	3 686,000	804
1875	2,535,000*	573*
United States—		
1900	4,240,000	562
1890	3,356,000	536
1880	2,082,000†	415†

* These figures are incomplete because of the omission of the building trades.

† These figures do not include proprietors and members of firms.

Proportionately to population, manufacturers provide more employment in the United Kingdom than in either of her two chief commercial rivals. This proportion has latterly increased at a slower rate than in Germany or the States. Nevertheless, an increase has taken place, so far as the twelve specified industries are concerned. For a complete comparison other smaller industries need to be enumerated and included. On that account too great a reliance should not be placed upon this last Table.

EDUCATION IN IRELAND.

The Irish people have suffered greatly from the want of an efficient national system of education. Religious and racial feuds have retarded reforms, and the Imperial Parliament has been slow to take the necessary steps to ensure a rational and adequate education of the people. But, as the seventieth report of the Commissioners of National Education in Ireland, just issued, shows, there is progress, slow but distinct, towards the standard of more advanced countries. At the time of the appointment of the Commission in 1831, Irish primary education was at a very low ebb. There were comparatively few schools, few trained teachers, no suitable school books, and no general, or approved system of instruction. Twenty years later, the condition of education had improved but was still very backward. The population of Ireland was then 6,552,385, and 47 per cent. of the inhabitants of five years old and upwards, could neither read nor write. In 1891 the population had fallen to 4,458,775, and only 14 per cent. of its inhabitants of five years old and upwards could neither read nor write. Nor must it be forgotten that it was the younger and better educated who emigrated to the number of 2,000,000 during this period, while the illiterates were persons who were too old to leave their homes. Again in 1871, of children of five years and under ten years of age, only 20 per cent. could read and write. In 1901, the per centage was 53·5. The growth of the national schools and attendance are shown in the following tables:—

	1861.	1901.
Population	5,798,967	4,458,775
National schools	5,830	8,692
Average attendance	284,726	482,031

And so with the national teachers—

	1861.	1901.
National teachers	6,500	11,897
Partially trained	3,048	5,588
Fully trained	3,452	6,309

Of the teachers now serving in such national schools 57 per cent. are trained, a much larger percentage than is found in England and Wales.

The number of illiterate voters who presented themselves at the last General Election showed that the condition of elementary education in Ireland was still very defective, and it was sought to diminish illiteracy amongst these classes by modifying the rules for evening schools so as to admit adults. The experiment has been more successful than was expected. In 1900 there were only 21 evening national schools, in 1903 there were 1,263.

But if there has been improvement in these ways in recent years much remains to be done in other directions. One of the most serious defects in the national system is the wretched condition of a large number of the school-houses. For many years past the Commissioners have been urging successive Governments to make adequate provision in the annual estimates for this purpose. As a result of these representations an Inter-departmental Committee inquired into the whole question in August, 1902. "This Committee," says the Commissioners, "reported to the Government, but up to the present neither a copy of their report, nor the decision, if any, arrived at by the Government and the Treasury has been communicated to us; and nothing has been done by the Executive to give effect to the recommendations of the committee. This inaction has not merely been indirectly injurious to the provision of suitable school houses, but it has actually brought to a standstill in hundreds of cases the work of building, owing to the desire of managers to await the publication of the new plans and scales of grants, and it has caused us to refrain from compelling managers of unsatisfactory schools to apply for building grants." The Commissioners are strongly of opinion that unsatisfactory school buildings are largely responsible for the slow rate of educational progress, and for the irregular attendance of pupils. The arrangements for heating, lighting, and cleaning the school houses are, as a rule, unsatisfactory except in the case of the model schools, schools vested in the Board, convent schools, and other large schools. In very many schools, especially those situated in remote or impoverished localities, these matters are almost entirely neglected.

The average daily attendance at these schools as compared with the number of pupils on the rolls is

low. It is only 482,489, or about 65 per cent. of the number on the rolls, as compared with 85 per cent. in Scotland. The attendance is, however, slowly improving from year to year, and it must be remembered that while attendance is compulsory throughout Scotland, only a comparatively small portion of Ireland is under the operation of the compulsory law. Moreover, the school houses in Scotland are better maintained than in Ireland, and the regularity of attendance of children is stimulated by prizes. In Ireland there are no funds for the awarding of school prizes, and local interest in education is much less keen.

The religious denominations of the pupils on the books on the 31st December, 1903, were as follows:—Roman Catholics, 74·2 per cent.; Episcopalians, 12·1 per cent.; Presbyterians, 11·5 per cent.; Methodists, 1·3 per cent.; the rest, 0·9. In his recent book on "Rome in Ireland," Mr. Michael McCarthy says that "Education has become almost entirely sectarian in the Irish primary or national schools," and the official figures show that there is substance in the statement. The percentage of schools having Roman Catholic and Protestant pupils in attendance steadily dwindles. In 1893 it was 45·5, and year by year without a break it has grown smaller until in 1903 it was only 33·1. And although there are in Ireland 2,853 schools attended by pupils of both denominations, 2,000 of these schools are under exclusively Roman Catholic teachers, and only a trifle over 5 per cent. of the pupils are Protestants. The remaining 853 schools are under Protestant teachers, and the percentage of Roman Catholic pupils is a little over 9 per cent. There are only 30 schools under conjoint Protestant and Catholic teachers, the attendance at which is 30 per cent. Protestant and 70 per cent. Roman Catholic. The following table is instructive:—

Religious Denominations.	Clerical.		Lay.	
	No. of Managers.	No. of Schools	No. of Managers.	No. of Schools
Roman Catholic	1,190	5,773	146	175
Late Established Church	707	1,063	247	409
Presbyterian	394	711	163	212
Methodist	62	90	11	15
Other Denominations	11	19	30	36
Total	2,364	7,656	597	847

These figures show that there are 5,948 Catholic national schools in Ireland, and of these 5,773 are under priest-managers, and only 175 under lay-managers, the priest having more than thirty-nine times the power of the layman. With the Protestant schools the lay element is much stronger. There are 2,555 non-Catholic national schools, and of these 1,883 are under clergymen-managers, and 672 under lay-managers, the cleric being less than thrice as powerful as the layman.

AUTUMN RAINFALL AND YIELD OF WHEAT.

The following memorandum prepared by Mr. Shaw, the secretary of the Meteorological Council, on the relation on the yield of wheat to the rainfall for the last 21 years, has been communicated to *The Times*, by Sir Richard Strachey, G.C.S.I., Chairman of the Meteorological Council:—

In the course of an inquiry into the distribution of rainfall and other meteorological elements in the seasons of the last 21 years, a relationship has been disclosed between the autumn rainfall and the subsequent yield of wheat which is so remarkable that it deserves special notice. For the purpose of this comparison "autumn" must be understood to mean the period from the 36th to the 48th week (both inclusive) of the year as dealt with in the *Weekly Weather Report*. The 13 weeks cover approximately the months of September, October, and November, and the rainfall is that given in the *Weekly Report* for the "Principal wheat-producing districts." The figures for each year are shown in the following table; the year given is the year in which the crop was gathered, the corresponding rainfall is that of the previous autumn. The figures for the yield of wheat express in bushels per acre the average yield for England as given in the annual returns of the Board of Agriculture, rounded off to the nearest half-bushel—

Year.	Yield of Wheat.	Previous Autumnal Rainfall.
	Inches.	Inches.
1884	30	8·5
1885	30·5	5·2
1886	27	10·2
1887	*32	7·8
1888	*28	7·0
1889	30	7·0
1890	31	6·5
1891	31·5	6·6
1892	26	9·7
1893	*26	9·0
1894	30·5	6·9
1895	*26	7·9
1896	*34	7·9
1897	29	10·0
1898	35	5·0
1899	*33	7·5
1900	28·5	8·0
1901	31	7·2
1902	33	5·8
1903	*30	5·5
1904	26·5	10·4
1905	—	4·2
Mean	30·0	7·3

* Anomalous years.

The obvious general conclusion to be drawn from this table may be briefly stated; disregarding for a moment the figures marked with an asterisk, the yield of wheat goes up as the autumn rainfall goes down, and *vice versa*.

But the relation indicated is much more specific than a mere general statement would imply. It may be put into a more precise form, as follows:—With certain exceptions every inch of autumn rainfall involves a diminution of the yield of wheat for the following year by a bushel and a quarter per acre. It may be premised that the extreme variation of yield was from 26 bushels in 1892, 1893, and 1895, to 35 bushels in 1898. If the yield be computed from the autumn rainfall by subtracting from the *datum* of 39·5 bushels per acre a bushel and a quarter for every inch of autumn rainfall, the "computed yield" obtained in this way shows an astonishing agreement with the actual yield given in the official returns.

In seven years out of the 21 the agreement is within half a bushel. But perhaps the general accuracy of the relationship is more strikingly manifest if the years when the calculation fails most signally to give the yield are considered. In seven of the years the actual yield differed from the computed yield by as much as 2·5 bushels or more, on the one side or the other. These are the years marked with an asterisk in the table. Two of the seven years were 1888 and 1903, when the crops were flooded by summer rains amounting to upwards of 10 in., and the yield fell below the computed value by 2·5 bushels in each case. The two exceptional years 1887 and 1899, when the crops exceeded the computed yield by 2·5 and 3 bushels respectively, are very interesting, for, although the autumn rainfall came up to the average as regards amount, it was so irregularly distributed that there were eight weeks out of the thirteen in the one case and ten weeks in the other, when the rainfall was less than the 20 years' average, the amount for the quarter being brought up to the average by exaggerated rainfall in a few weeks. These might, therefore, be called dry autumns from a certain point of view, in spite of their having the average total rainfall, and the yield corresponds with the results for dry autumns rather than one with average rainfall. The two consecutive years 1895 and 1896 are also interesting; 1895 is memorable as the year of the extremely cold February, a truly anomalous year. Its yield of wheat was 3·5 bushels below the computed amount, but, strange to relate, the following year, which had in addition the advantage of a very dry winter, gave a yield above the computed return by 4·5 bushels per acre, as though the unused productive power of 1895 had not been lost in consequence of the exceptional cold, but stored. The two years taken together would agree admirably with the rule. The remaining exception year is 1893, a year of phenomenal drought.

Thus every year when the difference between the computed and actual yield is more than two bushels is otherwise conspicuously anomalous, except the years 1887 and 1899, and for those years the divergencies have been already, to some extent, explained. In the remaining seven years the computed yield differs from the actual yield by an amount between half a bushel and two bushels. An examination of the details of the statistics does not diminish the evidence of correspondence between the two sets of figures, but we need not consider the details here.

Various reasons may be given for regarding the autumn rainfall as likely to influence the yield of wheat; the washing of nitrates from the soil by the rain or the postponement of sowing to the spring on account of the wet are, no doubt, effective, but that all causes should combine to make the dryness of autumn the dominant factor in determining the yield, as it clearly is, is very remarkable.

The averages both of yield and of rainfall are taken over large areas; the figures are, in fact, the only ones immediately available for the purpose of such a comparison in the returns of the Board of Agriculture and the Meteorological Office respectively. What modification the induction would suffer if the inquiry were to be pursued for separate districts or individual fields has yet to be determined.

In the meantime the relationship clearly indicates a clue to such phenomena as the deficiency of yield in 1904, after the favourable seasons of that year, in the excessive autumn rainfalls of 1903; and it is sufficiently remarkable that when I first compnted the yields on the principle of deducting from 39·5 a bushel and a quarter for each inch of autumn rainfall, and extended the calculation to the years 1904 and 1905, without knowing at the time the wheat yield of either year, the computed yield of 1904, 26·5 bushels per acre, was subsequently found to agree with the actual yield, which is entered at 26·52 bushels in the official returns. This agreement at once raises the interesting speculation whether the exceptionally large yield of 34·5 bushels per acre for 1905, computed from the small autumn rainfall of 1904, will be borne out to the same degree of accuracy. At any rate, it seems clear that in the absence of some extraordinary abnormality of the seasons between now and next September the yield of wheat for England must be unusually large.

W. N. SHAW.

THE GROWTH OF LOCAL EXPENDITURE.

The growth of expenditure by local authorities has of late years been very rapid, and the Local Taxation Returns just issued give no indications of slower expansion. They afford much occasion for thought and even anxiety. In the financial year 1884-5 the total expenditure (including expenditure defrayed out of loans) was £44,053,904, in 1902-3 it had risen to £92,882,545; that is to say in less than twenty years it had much more than doubled. But this rapid growth is slow as compared with that of expenditure defrayed out of loans. In 1884-5 this expenditure was £9,853,795, in 1902-3 it had risen to £36,968,198; in less than twenty years it had nearly quadrupled. The total expenditure which stood at £53,907,699 in 1884-85, had risen in 1902-3 to

£128,968,743. Examination of the details of loan expenditure show the main increases to be as below:—

	1884-5. £		1902-3. £
Electricity Supply	—		4,161,794
Highways and Street Improvements	2,399,688	..	6,228,760
Lunatic Asylums	260,858	..	1,124,244
Works, Open Spaces, &c.	92,200	..	804,540
Public Buildings and Offices	170,773	..	386,604
Schools	1,385,508	..	2,312,051
Sewerage	985,385	..	2,502,611
Tramways	108,517	..	4,675,591
Waterworks	1,231,598	..	4,304,959

The amount of the outstanding loans has more than quadrupled in the last thirty years, standing at £92,820,100 in 1874-5, and at £370,607,493 in 1902-3. The returns distinguish as far as practicable authorities acting for areas which were—(1) Metropolitan, (2) extra-metropolitan but wholly urban, (3) partly urban and partly rural, and (4) wholly rural. Taking 1874-5 and 1902-3 as the years of comparison, the increases under these several heads are as follows:—

	1874-5. £		1602-3. £
Metropolitan	21,007,799	..	67,518,225
Extra-metropolitan, but wholly Urban	61,516,173	..	270,042,566
Extra-metropolitan, partly Urban, partly Rural	10,113,975	..	28,621,641
Wholly Rural	182,163	..	4,428,061

It will be seen that the increase in the "Wholly Rural" expenditure has been comparatively much more rapid than elsewhere, and that there has been an increase in "Extra-metropolitan, but wholly Rural" of no less than £208,526,403.

Gross estimated rental and rateable value show remarkable increases, but nothing like the growth of expenditure:—

England and Wales.	1874 75. £		1902-3. £
Gross estimated Rental	136,408,462	..	231,089,809
Rateable Value	115,646,631	..	191,106,528

In the metropolis the growth has been proportionately larger:—

Gross estimated Rental	25,148,033	..	48,895,764
Rateable Value	20,672,765	..	40,677,589

It follows from the foregoing figures that the burden of the rates has become much heavier. In 1874-5 the estimated population of England and Wales was 23,724,834, and the average amount per head of population of public rates raised was 16s. 2d., in 1902-3 it had risen to £1 10s. 6d. In the same period the average amount, per head of population, of loans outstanding had increased from £3 18s. 3d. per head to £11 4s. 8d. If London alone is taken the figures show that London has relied less upon loans than the Provinces. The Londoner pays nearly three times as much in rates as he did thirty years ago, as from £1 4s. 11d. in 1894-5 to £3 0s. 5d. in 1902-3; but the average amount per head of population of loans outstanding has not very much more than doubled, as from £6 2s. 7d. to £14 14s. 11d. If Government grants and Local Taxation Duties and other sums received from Imperial funds by local authorities are considered, it will be found that the average amount per head of population in London has increased from 2s. 11·3d. in 1874-5 to 9s. 5·0d. in 1902-3, and in the rest of England and Wales from 1s. 1·9d. to 7s. 6·3d., whilst the average amount per fund of rateable value has increased in London from 5·9d. in 1874-5 to 1s. 0·7d. in 1902-3, and for the rest of England and Wales from 3·0d. to 1s. 5·1d. The principal purposes for and in respect of which the local authorities of England and Wales received moneys from Imperial funds, and taking the greatest increases in the thirty years, are shown below:—

	1874-5. £		1902-3. £
Administration of Poor Law and Relief, &c.	178,271	..	1,061,873
Maintenance of Lunatics	180,536	..	766,066
Education (elementary and others)	69,677	..	5,234,959
Police	1,187,399	..	2,393,514
Salaries of Medical Officers, Sanitary Inspectors, &c.	50,572	..	154,326
In respect of the deficiency caused by the Agricultural Rates Act, 1896, in the produce of rates	—	..	1,328,019
Under provisions of Local Government Act, 1888, in aid of rates	—	..	1,815,823

The total grants incurred in the period advanced from £1,681,399 to £12,849,284. It will be remembered in connection with the outstanding loans of the local authorities that the majority of those owing for harbours, piers, and docks are not charged on the rates. Others, such as those incurred for waterworks, gas works, and markets are primarily charged, in many cases, on the revenues of the undertakings for which they have been raised, and constitute a charge on the rates only in the event of such revenues proving insufficient to meet the amounts payable as interest on the loans, and the amounts required to be provided for the repayment of the loans.

PAUPERISM IN TOWN AND COUNTRY.

The pauperism returns for 1904 show that the increase of indoor pauperism, both actual and proportionate, in the year was considerable, and that for the quarter ended December 31st, it was higher than at the corresponding date in any of the preceding forty years. But the most striking fact to be learned

from the tables is the comparative growth of London pauperism. If the country—that is to say England and Wales—as a whole, is taken, we find that although pauperism has increased in the last three years—as from a ratio per 1,000 inhabitants of 21·8 in 1901, to 24·2 in 1904—taking indoor and out-door combined it was lower in 1904 than in any year earlier than 1890. If the paupers had borne the same proportion to estimated population at the end of December in 1904, as they did in the same period in 1874, 1884, and 1894 respectively, the numbers would have been—in the same proportion as 1874, 1,067,935, instead of 816,216; 1884, 907,564, instead of 816,216; 1894, 821,557, instead of 816,216. But if we limit the review to London, much less satisfactory figures are revealed. Taking indoor and out-door pauperism combined, the ratio per 1,000 inhabitants—26·7—is higher than for any year since 1874. And if the paupers had borne the same proportion to estimated population in the last week of December, 1904, as they did in that week in 1874, 1884, and 1894, it would be found that the position has worsened instead of bettered as is the case with the country as a whole. The numbers would have been as follows:—In the same proportion as in 1874, 132,065 instead of 124,409; 1884, 110,965, instead of 124,409; 1894, 111,371, instead of 124,409.

A large part of the increase in the last quarter—71,904—was, however, attributable to a few districts only. The net increase in London (chiefly in the Poplar and Wandsworth Unions) at the end of the quarter was 10·4 per cent. In the Croydon Union it was 78·2 per cent., and in the West Ham Union, where the numbers rose during the quarter from 14,655 to 29,776, the increase was 103·2 per cent.

The growth in indoor pauperism is very marked. Taking England and Wales as a whole, the ratio per 1,000 inhabitants—7·6—was higher in 1904 than for any year covered by the tables, that is to say, during the last forty years. And so with London, where the ratio per 1,000 inhabitants for 1904 was 16·5. In 1864 it was only 10·3. It is very noticeable, too, that whilst taking the whole country, the ratio of indoor paupers in 1904 was 7·6 and of outdoor 16·6; in London the figures are respectively 16·5 and 10·2. Turning to outdoor paupers, the figures show a decrease in the country as a whole from 37·9 in 1864 to 16·6 in 1904, and in London from 23·3 to 10·2; but whereas the ratio in 1904 for the country at 16·6 was lower than for any year prior to 1896, the ratio for London at 10·2 was higher than for any year since 1887.

WEST INDIAN AGRICULTURAL CONFERENCE, 1905.

The fifth West Indian Agricultural Conference was held at Port-of-Spain, Trinidad, from January 4th to 13th. The representatives included the principal officers connected with the chemical, botanical and educational services in the West Indies, aud the scientific officers on the staff of the Imperial Department of Agriculture, as also delegates from the Agricultural Boards and the chief Agricultural Societies.

The Conference was formally opened on January 4th by the Governor (Sir Henry M. Jackson, K.C.M.G.). In his opening address the President of the Conference (Sir Daniel Morris, K.C.M.G., the Imperial Commissioner of Agriculture) reviewing the agricultural situation, expressed the opinion that marked progress had taken place in regard to the sugar-cane, cacao, cotton, and other industries, and referred to the hearty manner in which the planters and the scientific men were working together for the welfare of the West Indies.

In the proceedings of the Conference a prominent position was assigned to the sugar-cane industry, the first subject on the agenda being the "Results of recent experiments with seedling canes and manurial experiments in the West Indies." A paper on the sugar-cane experiments in British Guiana, by Professor J. B. Harrison, was read. Professor J. P. d'Albuquerque then presented some of the results of the experimental work in Barbados, who was followed by Dr. Watts, who dealt with the experiments in the Leeward Islands. A paper showing the excellent results that had been obtained with seedling canes on a group of estates in Trinidad was presented by Dr. Urich.

The next subject brought up for discussion was the Cane-farming Industry. The discussion was opened by the Hon. B. Howell Jones (British Guiana) and Professor P. Carmody (Trinidad). Sir Henry Jackson described a very satisfactory system of cane farming in vogue in Fiji.

Other papers that were presented to the Conference in connection with this industry included reviews of the principal insect and fungoid pests of the sugar-cane, the field treatment of cane "tops" for planting, and the polarometric determination of sucrose.

Trinidad being the foremost cacao-producing colony in the West Indies, considerable interest attached to the discussion of important subjects relating to that industry. Mr. Hart read a paper dealing with experiments that are being carried on with the view of improving the health and productiveness of cacao trees. This was followed by a paper prepared by Mr. J. G. de Gannes, one of the leading cacao planters in Trinidad. Among the points raised in the discussion which received considerable attention was that of shade for cacao trees. It was apparent that widely-divergent views were held in this connection in the various islands. In Trinidad, it was considered that shade trees were indispensable; in Grenada, cacao trees did not appear to require shade; while in other islands cacao was grown both with and without shade. It was suggested by the president that a series of experiments might be carried out in Trinidad by the Agricultural Society with a view to obtaining definite information on the subject.

The attention of the Conference was next turned to the fruit industry. Mr. J. R. Bovell (Barbados) read

a short paper upon the efforts to establish a fruit industry in Barbados. The president briefly reviewed the situation, pointing out that the conditions in the different islands as regards the export of fruit were very dissimilar. Barbados enjoyed an advantage over the other islands in this matter, since Barbados was the last port of call. Experience had shown that fruit could be satisfactorily shipped from Barbados to England for eight months of the year in the ordinary holds of the vessel, without cool storage, provided the ships were adequately ventilated. Two of the ships of the Royal Mail Company had been fitted with cold storage, and, in the case of shipments by these vessels, there had been no difficulty as to the condition of the fruit on arrival. The industry could not be in an entirely satisfactory condition until all the ships had been fitted up in the same manner.

The subject of the recently established cotton industry was next brought forward. Brief statements were made by Mr. J. R. Bovell (Barbados), Dr. Watts (Leeward Islands), and Mr. W. N. Sands (St. Vincent).

Attention was also devoted to matters connected with agricultural education. The results of the efforts that have been made to introduce the teaching of the principles of agricultural science into colleges and secondary schools were reviewed by Mr. Horace Deighton and Professor d'Albuquerque (Barbados), and Professor Carmody (Trinidad). Mr. J. H. Collens, Inspector of Schools, read a paper on school gardens and school shows in Trinidad.

AUSTRALIAN PRIMARY EDUCATION.*

If there is any one point on which the Australian people are unanimous it is the right of every child to have the means of education placed within his reach, and it is very rarely that exception is taken in the State Parliaments to the cost of popular instruction, which, so far as the public schools were concerned, amounted in 1902-3 to £2,002,391, or more than 10s. per head of population. Each State has its own educational system, but all are on a secular basis, and ample provision is made for enabling children in the most remote parts of the Commonwealth to obtain a fair share of instruction. In New South Wales a public school may be established in any place where a regular attendance of not less than twenty children is guaranteed. Where the number is less a provisional school may be formed. There are also half-time schools, where twenty children, within a radius of ten miles, can be assembled in groups of ten each; and, in addition, house-to-house schools, where three or more groups are placed under an itinerant teacher. In the case of these two latter, the residents have to provide the necessary rooms, but all other charges are borne by the State. Private tutors, or governesses, are subsidised to the extent of £5 per head on an average attendance up to a maximum of £25 per annum, subject to the condition that two families share in the tuition, and that there is no State school readily accessible. In Victoria the conditions are much the same as in New South Wales, but it is not customary to start a full-time school unless there is a reasonable chance of an average attendance of at least fifteen children being maintained. Where the number of children is less, the schools are either made half-time, or the parents are paid for the conveyance of their children to school. This is found more economical than having separate schools for a dozen or less children each. Where there is railway communication the fares for school children are largely reduced. In Queensland, there must be an average attendance of thirty children to secure the opening of a State school, which may not, however, be too near one already established. In addition the residents must be prepared to pay one-fifth of the cost of erecting and furnishing the necessary buildings. A provisional school may be established where the average attendance will not be less than twelve, and the nearest existing school is not less than twelve miles distant, but the residents are required to defray one-fifth of the cost of erection and furnishing. There are also a few half-time provisional schools. In South Australia a public school may be established where an average attendance of twenty children can be maintained; and a provisional school where the attendance is under twenty, but not less than twelve. There are also half-time and special schools, the latter giving full-time instruction, although the attendance is less than twelve. The whole of the cost is borne by the State, which also pays a fair rental for any buildings provided by residents for use as provisional or special schools. In Western Australia an average attendance of twenty children is necessary to secure the establishment of a public school. Half-time schools are allowed where the aggregate attendance at the two divisions numbers sixteen. Provisional schools may be established where there is no other school within four miles and where an average attendance of from ten to nineteen children can be secured. In sparsely-populated districts house-to-house schools are permitted. Special schools may be established in places too remote from the metropolis to be regularly inspected. In these the teachers are paid salaries higher than those given in ordinary State schools of the same size. In Tasmania, a State school must have an average attendance of not less than twenty children. In thinly-populated districts, provisional schools may be formed, and itinerant teachers employed where the families are so scattered that the children cannot be gathered into a single school. Occasionally, where there is a falling off in the standard attendance, the schools receive special assistance. There are night schools in several of the States, but the number is rapidly declining. At the close of 1902 there were 7,218 State schools in the Commonwealth, with an average enrolment of 597,935, and an average

* Communicated by Mr. J. Plummer, of Sydney, New South Wales.

attendance of 455,343; the average annual cost per scholar in average attendance being £4 2s. 9d., or including cost of school premises, £4 12s. 8d. The cost is highest in Western Australia, and lowest in Tasmania. In return for this expenditure, school attendance has been made compulsory in the various States, but the law is not always stringently enforced. These figures do not include the private schools, of which there are a large number, with an attendance of several thousand children. This widely-spread diffusion of popular education explains the fact not only why Australians are such extensive readers, but also why almost every township, however small, boasts its local paper, sometimes two or more, where the population is not much larger than that of a good-sized English village.

JAPANESE INDUSTRIES.

According to recent returns there are 840 factories in Japan in which the services of chemists are permanently engaged. This number does not include only chemical factories in the narrow sense of the word, but also gas works, paper works, ceramic and lacquer works; sugar factories and breweries are not comprised within them. Of the 840 works above mentioned, steam and water-power are used in 190. There are only two establishments employing more than 500 workpeople; 86 more than 100; 207 more than 50; and in 348 more than 30 operators are engaged. Among the joint stock companies comprised in the above enterprises there are 75 for the production of salt, 43 for the production of pharmaceutical products, 95 for illuminating oils, 40 for matches, 49 for the manufacture of indigo, 4 for other colours, 4 for gas, 6 for the production of incense. The Japanese chemical industry gives employment to 38,591 workpeople, according to a report published recently by the Japanese Government, of whom 12,966 are in establishments run by steam and water-power, and 25,625 in the remaining factories. In the match factories there are five women operatives to each man. The average number of hours worked is twelve, while in the more important factories this number is reduced to ten. The average wages of the men are about 7d., and of the women about 5d. In match factories the women over 14 years of age receive from 2½d. to 6d. a day, and below that age from less than 1d. to 3d. a day. According to the latest statistics of production, the output of lighting oils in 1899, in Japan represented a value of about one million sterling; sulphate of potash, in 1898, £26,000; sulphate of soda, £86,000, and sulphuric acid, £90,000. The Japanese Government takes a very keen interest in industrial progress, and endeavours to promote it by means of industrial associations, periodical literature, and numerous educational establishments, where technical instruction is given, *inter alia*, in dyeing, lacquering, gilding, metallurgy, and brewing.

THE PEARL OYSTER FISHERY OF CEYLON.

A recent report of Mr. James Hornell, the marine biologist to the Ceylon Government, deals with the decrease among the fishable oysters since March 1902. It seems that the factors which tend to reduction in the number of oysters in any bed fall under two categories: (*a*) those which affect spat, and oysters under one or two years of age; and (*b*) those which militate against the well-being of those in or approaching the pearl-producing stage. In one particular quarter, sand disturbances effected a great deal of harm. In 1900 the whole area was thickly spread with oysters, but with every recurrent period of stormy weather these oysters suffered thinning by encroachment and overwash of sand. A subsidiary cause of destruction was the ravages of the boring sponge, *Clione indica*, which was specially active in one section, riddling the valves and sapping the vitality of the oyster by the drain it causes upon the nacre-secreting glands. Out of 400 specimens examined, 310 were affected by *clione*, leaving less than 23 per cent. as the proportion free from infection. In another case overcrowding had serious results, on account of the huge deposits of spat which fell upon the older oysters. In the first year the effects were very little marked, but "little by little, as the myriads of newcomers flourished and increased in size, the well-being of the older generation was affected, a result that showed itself first by arrest of the growth of the shell, and then by starvation, lowered powers of reproduction, and wide-spread mortality." Owing to the exceptional activity of the pearl oyster during six or twelve months of its existence, the younger generation has a great advantage over the older in the struggle for existence. The young ones mount on the topmost parts of the older ones, and intercept food particles which would otherwise pass to the latter.

Mr. Howell looks to a break in the fishery cycle in 1907, a more or less prolonged blank cycle, whereof the duration will be largely dependent upon whether large measures of transplantion be resorted to, seeing that in certain districts no fall of spat has taken place for two years.

GENERAL NOTES.

CULTIVATION OF TEA IN THE CAUCASUS.—A recent Diplomatic and Consular Report (No. 628, Miscellaneous Series), contains a memorandum by Mr. P. Stevens, His Majesty's Consul at Batoum on the cultivation of tea in the Caucasus. The industry seems to be progressing very satisfactorily, about 810 acres being under cultivation. The crop in 1902 amounted to 36,900 lbs., and increasing slightly yielded 38,700 lbs. in 1908. The prices obtained from 1s. 3d. to 5s. per Russian lb. (or 0·9 English lbs). The

cheapest qualities are purchased by the Russian Government for the use of its troops, while the medium qualities find a ready market in Moscow, Kharkoff and other towns where they are purchased by the municipalities for use in hospitals, asylums and kindred institutions. It is feared that with the increase of the area under cultivation, a great scarcity of labour will be experienced, especially at the picking seasons. At the present cost of labour, assuming an average selling price of one rouble per Russian pound, each dessiatine (2·7 acres) of properly cultivated land should yield a clear annual profit of 400 roubles, no allowance being made for administration expenses, It is pointed out that a rise of 25 per cent. in the price of the labour needed for hoeing and picking in the summer would increase the annual expenses by 65 roubles per dessiatine, proportionately reducing the profit.

RAPID TRANSIT FOR PRODUCE.—The efforts of the Italian Chamber of Commerce in London to induce Italy to accelerate the speed of trains carrying fruit and agricultural produce generally from Italy to the northern ports of Europe seem likely to be successful. It is proposed to despatch a train twice weekly from Milan to Antwerp, the trains from the rest of Italy concentrating at Milan, and covering the journey thence to Antwerp in 48 hours. The goods will then pass *viâ* Harwich to the London and provincial markets. France has already established a service of the kind from her warmer latitudes to her northern ports, and the transit trains from Vienna reach London (nearly 1,000 miles in a direct line) in 48 hours. The new railway through the Simplon Tunnel must relieve the traffic on the Mont Cenis and St. Gothard lines, and will be the fourth trans-Alpine tunnel constructed in living memory. These three routes will become more and more competitors for the traffic to the United Kingdom, the Splügen route being reserved for Germany, Russia, and Central Europe.

HIGH TARIFFS AND IMPORTS.—In reviewing the British iron and steel exhibits at St. Louis, Mr. Seymour Bell, the British Commercial Agent in the United States, mentions incidentally that American experience shows that a high tariff does not always prevent a great increase of imports. Thus, the importation of knives to the United States in 1903 showed an increase of 13 per cent. over that of 1902, though the average duty paid was 78·19 per cent., *ad valorem*. Scissors increased 27 per cent., the duty averaging 51·50 per cent., *ad valorem*. That orders are not always looked after by British manuracturers as they might be is instanced by a conversation Mr. Bell had with the representative of an American concern working under British patents. This representative declared that he had received personal inquiries from visitors from Europe for some of their manufactures. He had to refer them to the British house, who were unrepresented at the Exhibition, as his company is prohibited from selling in Europe. This was merely quoted to show how easily orders may be lost when a comparatively small outlay would show the goods to the world.

THE POPULATION OF FRANCE.—According to official statements appearing in the French *Journal Officiel*, the excess of births over deaths in 1903 was 73,106; in 1902, 83,944, or 157,050 in two years, which, added to the population as determined in 1901, namely, 38,961,945, makes the number of inhabitants in France in 1903, 39,118,995. There were 826,712 births in 1903, against 845,378 in 1902, a decrease of 18,666 and a decrease of 24,332, as compared with the average birth-rate of the last ten years. The number of deaths in 1903 was 753,606, a a decrease of 7,828 as compared with 1902, and a decrease of 54,788 in comparison with the average for the past ten years. The number of marriages recorded in 1903 was 295,996, an increase of 1,210 as compared with 1902, and 4,119 in comparison with the last decennial average. The number of divorces is steadily increasing, being 8,919, or 488 more than in 1902, and 1,758 more than the average for the past ten years. The increase in the population is not due to a larger birth-rate, for the number of births in 1903 was the smallest in the last ten years, but to a decrease in the annual number of deaths, the latter in 1903 being less than in any year since 1893, with the exception of 1897.

BRITISH TRADE WITH MOROCCO.—Mr. Vice-Consul Smith's report upon the trade of Tangier and district for 1903 mentions the possibility of furthering trade between Morocco and Great Britain in certain directions. For example, British tanners might do well to give Moorish goat-skins a trial. They are at present being exported in large quantities to America, *viâ* the United Kingdom. These goat skins are sold f. o. b. London at an average price of 9d. per lb. The skins exported from the Tangier district are reported to be the finest in Morocco, and native dealers are paying considerably more attention to the selection and preparation of them than formerly. There is again a large market in Morocco for semolina, in which Mr. Consul Smith thinks British traders should be able to compete favourably, and it might be worth their while to procure samples of the qualities required for the Morocco market. With the rapidly-increasing population at Tangier, the building trade has received a great stimulus and there is a large demand for building material of all descriptions. At present the bricks and tiles are mostly of French origin. The tables of exports and imports show that French trade made more progress in the year under review than that of any other country; German trade too seems to be gradually retrieving its position largely owing to cheap freights on German lines, and cheap handling at the German ports of discharge. But at the ports of Tangier and Laraiche the United Kingdom is still

(saving Spain) well ahead of other nations. It is a matter for regret that the Consular reports for 1903 relating to Morocco are only available to the public in February, 1905. The long delay in their publication deprives them of much of their value.

PREPARATION OF MICA FOR THE MARKET.—A paper recently read by Mr. G. A. Stonier before the Institute of Mining and Metallurgy, on "Mica Mining in Nellore (Southern India)," contained some remarks on the manner in which the material mined is prepared for the market. The mica is carried from the mines to the dressing-sheds in saucer-shaped baskets, 18 inches in diameter and 6 inches deep. The headman selects and personally splits up the good plates with a piece of hoop-iron, or with a cheap knife (with 3-inch blade and 4-inch handle, bought for a couple of annas in the bazaar), into flat pieces, free from flaw or cross-graining, about one-eighth of an inch in thickness. These pieces are passed on to women or children, who, with a knife, and a sheet of tin or zinc as a templet, mark on them as large a rectangle as possible. The cutting along these ruled lines is then done by men with ordinary European garden-shears, of which one end is firmly embedded in a block of wood buried in the ground, so that the cutting edge lies in a vertical plane. The poorer qualities of mica are treated in the same way, and the rectangles are tied into bundles of various sizes and grades according to conditions. In obtaining 143 tons of mica at Nellore, 2,097 persons were employed in 1902.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock :—

MARCH 1.—"The British Art Section of the St. Louis Exhibition." By ISIDORE SPIELMANN, F.S.A. SIR EDWARD POYNTER, Bart., P.R.A., will preside.

MARCH 8.—"Ethics of Japanese Society." By BARON SUYEMATSU. The RIGHT HON. LORD REDESDALE will preside.

MARCH 15.—"Methods of Design in Mohammedan Art." By E. H. HANKIN.

MARCH 22.—"The Present Aspect of the Fiscal Question." By SIR CHARLES MALCOLM KENNEDY, K.C.M.G., C.B.

MARCH 29.—"British Woodlands." By the RIGHT HON. SIR HERBERT MAXWELL, Bart., M.P.

APRIL 5.—

APRIL 12.—"The use of Wood Pulp for Paper Making." By CHARLES PHILLIPS.

Dates to be hereafter announced :—

"The Protection of Buildings from Lightning." By KILLINGWORTH HEDGES, M.Inst.C.E.

"The Supply of Electricity." By JAMES NELSON SHOOLBRED, B.A., M.Inst.C.E.

"Application of Electricity to the Location of Mineral Deposits." By ALFRED WILLIAMS.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock :—

MARCH 16.—"Manipur and its Tribes." By T. C. HODSON (late I.C.S.).

APRIL 6.—"The Prospects of the Shan States." By SIR J. GEORGE SCOTT, K.C.I.E. ("Shway Yoe"), Superintendent and Political Officer, Southern Shan States.

COLONIAL SECTION.

Tuesday afternoons at 4.30 o'clock :—

FEBRUARY 28.—"The Manufactures of Greater Britain.—I. Canada." By C. F. JUST, Canadian Government Service in London. The RIGHT HON. VISCOUNT RIDLEY will preside.

MARCH 28.—The Manufactures of Greater Britain.—II. Australasia." By the HON. WALTER HARTWELL JAMES, K.C., Agent-General for and late Premier of Western Australia.

MAY 11.—"The Manufactures of Greater Britain.—III. India." By HENRY JOHN TOZER, M.A.

MAY 23.—"The Cape to Cairo Railway." By SIR CHARLES H. T. METCALFE, Bart., M.Inst.C.E.

APPLIED ART SECTION.

Tuesdays, at 4.30 or 8 o'clock :—

MARCH 21, 8 p.m.—"West Country Screens and Rood Lofts." By F. BLIGH BOND, F.R.I.B.A. G. F. BODLEY, R.A., will preside.

APRIL 11, 4.30 p.m.—"The Monumental Treatment of Bronze." By J. STARKIE GARDNER. SIR GEORGE BIRDWOOD, K.C.I.E., C.S.I., will preside.

MAY 16, 4.30 p.m.—"Popular Jewelry." By MONSIEUR LALIQUE (Paris). ARTHUR LASENBY LIBERTY, J.P., will preside.

CANTOR LECTURES.

Monday evenings, at 8 o'clock :—

DUGALD CLERK, M.Inst.C.E., "Internal Combustion Engines." Four Lectures.

LECTURE III.—FEBRUARY 27.—*Examples of Internal Combustion Engines in Britain.*—Coal gas and producer gas engines, Crossley, National, Stockport—Blast furnace gas engines, Cockerill, Oechelhauser, Koerting, Crossley, National—Petrol engines, Wolsley, Liddeley, Daimler—Heavy oil engines, Deisel, Hornsby, National, Crossley.

LECTURE IV.—MARCH 6.—*Future Developments*—Suction producers—Blast furnace gas—Producer gas in power-stations—Marine gas and oil engines—Line of advance.

HERBERT LAWS WEBB, "Telephony." Four Lectures.

LECTURE I.—MARCH 13.—*Telephone Instruments.*—The telephone industry—The Bell tele-

phone—Telephone receivers—Telephone transmitters—Evolution of the modern transmitter—Design of transmitters and receivers—Signalling appliances—Complete telephone instruments—Protective appliances—Special forms of telephones—Special uses of the telephone.

LECTURE II.—MARCH 20.—*Telephone Lines.*—Characteristics of telephone current—Necessity for metallic circuits—Overhead lines—Types of telephone line construction—Telephone cables—Evolution of special type of cable for telephone work—Conduits—Distribution—Aerial cables—Means of increasing range of transmission—Long distance telephony.

LECTURE III.—MARCH 27.—*Telephone Exchanges.*—Requirements of a telephone exchange—Early types of switchboard—Evolution of multiple switchboard—Switchboard signals—Automatic signals—Various types of exchanges—Various methods of operating—Common battery exchanges—Distribution of wires—Power plant—Telephone buildings—Automatic exchanges—Conduct of telephone traffic.

LECTURE IV.—APRIL 3.—*Development and Tariffs.*—Supremacy of telephonic communication—Essential features of modern telephone service—Organisation of telephone plant and business—Evolution of telephone rates—Scientific telephone tariff—Effect of area on cost—Varying demands of consumers—Graded classes of service—Telephone development in different countries—Long distance service and rates.

ALAN S. COLE, C.B., "Some Aspects of Ancient and Modern Embroidery." Two Lectures.

May 1, 8.

HENRY WILLOCK RAVENSHAW, Assoc. M.Inst.C.E., Mem.Fed.Inst.Min.Eng., "The Uses of Electricity in Mines." Two Lectures.

May 15, 22.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, FEB. 27...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Mr. Dugald Clerk, "Internal Combustion Engines." (Lecture III.)

Farmers' Club, Whitehall-court, S.W., 4 p.m. Mr. Anker Simmons, "The Heavy Pressure of Taxation on the Agricultural Interest."

Surveyors, 12, Great George-street, S.W., 8 p.m. Mr. Harold Griffin, "Some Proposals for Improving the Law and Practice of Rating Property."

Geographical, University of London, Burlington-gardens, W., 8½ p.m.

Actuaries, Staples-inn Hall, Holborn, 5 p.m.

Camera Club, Charing-cross-road, W.C., 8½ p.m.

Medical, 11, Chandos-street, W., 8½ p.m.

TUESDAY, FEB. 28...SOCIETY OF ARTS, John-street, Adelphi, W.C., 4½ p.m. (Colonial Section.) Mr. C. F. Just, "The Manufactures of Greater Britain—I. Canada."

National Service League, Caxton-hall, Westminster, S.W., 5½ p.m. Admiral Sir Edmund Fremantle and Major Raymond Smythies, "The Naval and Military Advantages of Universal Naval and Military Training."

Colonial, Whitehall Rooms, Whitehall-place, S.W., 4½ p.m. Mr. Hubert Reade, "English Schools and Colonial Education: How can they be linked."

Royal Institution, Albemarle-street, W., 5 p.m. Prof. Karl Pearson, "Some Recent Biometric Studies." (Lecture I.)

Central Chamber of Agriculture (at the HOUSE OF THE SOCIETY OF ARTS), 11 a.m.

Medical and Chirurgical, 20, Hanover-square, W., 8½ p.m.

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Mr. Richard William Allen, "Surface-Condensing Plants, and the Value of the Vacuum Produced."

Anthropological, 3, Hanover-square, W., 8½ p.m.

Horticultural, Vincent-square, S.W., 3 p.m. Hon. J. H. Turner, "Fruit Growing in British Columbia."

WEDNESDAY, MARCH 1...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. Isidore Spielmann, "The British Art Section of the St. Louis Exhibition."

Royal Archæological Institution, 20, Hanover-square, W., 4 p.m.

Obstetrical, 20, Hanover-square, W., 8 p.m.

THURSDAY, MARCH 2...Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

Linnean, Burlington-house, W., 8 p.m. 1. Rev. T. R. R. Stebbing, "Zoological Nomenclature. International Rules and others." 2. Dr. G. Herbert Fowler, "Biscayan Plankton. Part IV. The Thaliacea."

Chemical, Burlington-house, W., 5½ p.m. 1. Mr. J. Campbell Brown, "The Latent Heat of Evaporation of Benzene and some other Compounds." 2. Messrs. F. B. Power and F. Tutin, "The Relation between Natural and Synthetic Glycerylphosphoric Acids." 3. Messrs. W. H. Perkin, jun., and S. S. Pickles, "The Reduction of Isophthalic Acid." 4. Mr. A. W. Stewart, "The Transmutation of Geometrical Isomers."

Royal Institution, Albemarle-street, W., 5 p.m. Prof. H. H. Turner, "Recent Astronomical Progress." (Lecture I.)

Electrical Engineers, 25, Great George-street, S.W., 8 p.m. Discussion on Mr. Donald Murray's paper, "Type Setting by Telegraph."

Civil and Mechanical Engineers, Caxton-hall, Westminster, S.W., 8 p.m. Mr. James F. Reade, "Engineering Expert Evidence."

Camera Club, Charing-cross-road, W.C., 8½ p.m.

FRIDAY, MARCH 3...Royal Institution, Albemarle-street, W., 8 p.m. Weekly Meeting 9 p.m. Chevalier G. Marconi, "Recent Advances in Wireless Telegraphy."

Art Workers' Guild, Clifford's-inn Hall, Fleet-street, E.C., 8 p.m. Paper on "Plaster Moulding and Casting."

Hospitals Association, Charing cross Hospital, W.C., 8 p.m. Mr. Donald J. Mackintosh, "The Control of Hospital Expenditure with Efficiency."

Geologists' Association, University College, W.C., 8 p.m.

Philological, University College, W.C., 8 p.m.

Quekett Microscopical Club, 20, Hanover-square, W., 8 p.m.

SATURDAY, MARCH 4...Royal Institution, Albemarle-street, W., 3 p.m. Mr. D. G. Hogarth, "Archæology" (Lecture II.)

Journal of the Society of Arts.

No. 2,728. VOL. LIII.

FRIDAY, MARCH 3, 1905.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

NOTICES.

NEXT WEEK.

MONDAY, MARCH 6, 8 p.m. (Cantor Lecture.) DUGALD CLERK, M.Inst.C.E., "Internal Combustion Engines." Lecture IV.

WEDNESDAY, MARCH 8, 8 p.m. (Ordinary Meeting.) BARON SUYEMATSU, "Ethics of Japanese Society."

Further details of the Society's meetings will be found at the end of this number.

CANTOR LECTURES.

On Monday evening, February 27th, Mr. DUGALD CLERK, M.Inst.C.E., delivered the third lecture of his course on "Internal Combustion Engines."

The lectures will be published in the *Journal* during the summer recess.

COLONIAL SECTION.

Tuesday afternoon, February 28th; the Right Hon. VISCOUNT RIDLEY in the chair.

The paper read was "The Manufactures of Greater Britain.—I. Canada," by C. F. JUST, Canadian Government Service in London.

The paper and report of the discussion will be published in a future number of the *Journal*.

CANTOR LECTURES ON MUSICAL WIND INSTRUMENTS.

Mr. D. J. BLAIKLEY'S Cantor Lectures on "Musical Wind Instruments" have been reprinted from the *Journal*, and the pamphlet (price One Shilling) can be obtained on application to the Secretary, Society of Arts, John-street, Adelphi, London, W.C. A full list of the Cantor Lectures, which have been published separately, and are still on sale, can be obtained on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

INDIAN SECTION.

Thursday afternoon, February 16th; SIR STEUART COLVIN BAYLEY, K.C.S.I., C.I.E., in the chair.

The CHAIRMAN regretted the cause of his presiding on this occasion, namely, the enforced absence of Lord George Hamilton.

The paper read was—

THE INDIAN CENSUS REPORT, 1901.

By SIR C. A. ELLIOTT, K.C.S.I., LL.D.

In drawing up this paper I have endeavoured to avoid coming into competition with the excellent paper read by Mr. Baines in March, 1903, and entitled "Gleanings from the Indian Census of 1901." He dealt mainly with the statistics then on record, for the report was not published till the middle of 1904. I have called my paper the "Indian Census Report," and in doing this I fear I have taken a rather presumptuous title, for the official report on the Census of 1901 is a vast compilation of statistics contained in three large quarto volumes, besides about 60 subsidiary volumes for the different provinces, and it is also a work of great erudition, enriched with information and speculation on many abstruse subjects connected with the ethnology and the religions and social customs of the people. It is idle to suppose that anyone could, in a short paper to be read before this Society, present anything like a complete sketch or review of so great an argument, and my effort will be simply to offer a few remarks, illustrating the most salient and interesting points, as a sample of the harvest to be gleaned by those who care to pursue the study of this important contribution to Anglo-Indian literature.

The Census of 1901 was carried out under the supervision of Mr. H. H. Risley, C.S.I., who has throughout his term of service shown a special interest in ethnological and social questions, and whose work on the "Tribes and Castes of Bengal," published in 1891, was a valuable addition to general knowledge. When he was promoted, in September, 1902, to the post of Home Secretary to the Government of India, the task of completing the report was handed over to Mr. Gait, who had distinguished himself in conducting the Census of Assam in 1891, and that of Bengal in 1901. Portions, however, of the present report, and especially parts of the chapters on religion, caste, and marriage, are Mr. Risley's own, and we owe the chapter on the 147 vernacular languages spoken in India to the accomplished pen of Dr. Grierson.

The Census of India has a static and also a dynamic side. The scientific man learns from it the actual facts concerning the population on a given date, while the administrator learns also the movement of the population, and the changes which have taken place during the past decade or series of years. The enumeration is a more elaborate business than it is in England or in any European country. It records not only the ordinary statistics as to number and density of inhabitants, age and sex, marriage and widowhood, and infirmities and occupations, but also as regards religion and the various sects into which the chief religions are split up, language and education, castes and the subdivisions of caste. In Mr. Risley's words (Report, p. 2)—

"It enables the rulers of India to take stock of their position, and to see how it has fared with the people committed to their charge. It fixes the statistical data on which all administrative action must be based. It tells the governing body what manner of men they have to deal with; how many will suffer from a failure of the rains, or will benefit by a well-conceived scheme of irrigation; what are the prospects of a new line of railway; what proportion of the population will be reached by a reduction of taxation; to what extent an overworked Government will be relieved by a transfer of jurisdiction, and what interests will be affected by the change."

The Indian Empire contains one and three-quarter millions of square miles, or more than the whole of Europe, excluding Russia. Within this area 294 millions of people were enumerated on the 1st March, 1901, of whom four-fifths were resident in British territory, and one-fifth in Native States. The mean density of the population was 167 per square mile, and it varied from 552 per square mile in the Delta of Bengal, to 150 in the Deccan, and 60 or 70 in Burma. There are many districts in Bengal and the United Provinces in which the density exceeds 500; some in which it approaches, and one in which it exceeds, 1,000 per square mile.

With such figures the spectre of over-population is ever present to the eyes of the Indian Government, and the first question for the solution of which we turn to the Census Report is: What is the rate of the increase? How fast is the flood mounting, and will a time come when it will overtop its barriers, and exceed the limits of food production? We have now had four censuses, more or less complete, in 1872, 1881, 1891, and 1901, and the answer given by the figures of this series is worthy of careful study. In 1872, the number counted was 205 millions, and it is now 294 millions; but we must not assume from this that there has been an increase of 89 millions in thirty years. The Census of 1872 did not include Kashmir or most of the Native States, and since that time Upper Burma, British Biluchistan, and several tracts on the borders of Assam and the Punjab have been added to British territory. Then again, there has been improved accuracy in the carrying out of every census, due both to the larger experience of the officials engaged in the work, and also to the gradual allaying of the fears and suspicions with which the operation was and still is to some extent regarded by large numbers of the people. After making these deductions, the recorded increase works out to the following figures:—

	Increase of Area. Millions.	Improvement of Method. Millions.	Real Increase of Popltn. Millions.	Total. Millions.
1872 81 ..	33	12	3	48
1881-91 ..	5½	2½	20	34
1891-1901	2½	—	4½	7
Total	41	14½	33½	89

The true growth of the population, after making allowances for the larger area of territory, and for greater accuracy in the enumeration, appears to be 33½ millions in 29 years, or 16 per cent.; not much more than ½ per cent. per annum. Such a result gives rise to a feeling of relief. It affords reason to hope that we are not drifting into certain disaster through the increase of popu-

lation up to a figure at which it would be impossible for the land to sustain them. On a survey of the entire conditions of the country, we may rest assured that there is sufficient room for expansion over the area still uncultivated, for improvement in the method of cultivation, and for the increase of artificial irrigation, to provide food and employment for a people increasing in number at this rate, if they will not exceed this rate, for many years to come.

But when we look closer into the causes which have controlled the rate of increase, we cannot feel the same satisfaction. In the period of 1872-81, there was a series of bad seasons, culminating in the great famine of 1876-8, and this kept down the growth of population to the small figure of 3 millions. The next decade was one of general agricultural prosperity, and was marked by no severe drought. As a result, the national increment was 26 millions, or nearly 10 per cent. In the last decade, the sufferings of the people from the two great famines of 1896-7 and 1899-1900 were very severe, and the effect of the mortality thus caused is shown in the small increase of 4½ millions. Had each of the three periods been as prosperous as the middle one, the population in 29 years would have grown, not by 34, but by 73 millions, and the danger of over-population and exhaustion of the soil would have been far more alarming. It is the business of the Government of India to cope with these seasonal calamities, and to draw their sting by measures of prevention and remedy. The more we are successful in doing this, the more urgent will the demand be for measures to increase the productive power of the soil, and to provide new occupations and new means of livelihood.

The total rise of 4½ millions in the population of the whole of India during the last decade is the resultant produced by combining together those areas in which there has been an actual decrease due to famine with those which have enjoyed fairly normal prosperity. The tract which suffered so grievously was about 600,oco square miles, or nearly a third of India, and comprised the whole of the Central Provinces, Central India, Rajputana and Baroda, the greater part of Berar, half of Bombay, two-fifths of the United Provinces, and a quarter of the Punjab. In this tract the population, which numbered 109 millions in 1891, fell to 98 millions, a loss of 11 millions, or over 10 per cent. On the other hand, in the rest of India there was an increase of 15 millions, or 8 per cent. The effect which a famine may produce in crushing out the vitality of a people could hardly be illustrated by more striking figures. It is not to be measured merely by the actual decrease. We must take into account what would have been the normal increase. The 109 millions in the area afflicted by famine would have risen, at the rate which prevailed in the rest of India, to 117 millions. They actually fell to 98 millions, so that to the direct and indirect effects of the two famines must be set down a loss of population amounting to 19 millions.

Perhaps a short account of the famine experiences of two or three provinces will enable you to realise the facts better than the statistics of the whole of India. In the small province of Berar, the number fell from nearly 3 millions to 2¾ millions, a decrease of 143,coo, or 5 per cent. But the vital statistics of previous years justified the expectation that the figure would have been higher by 297,000, so that mnst be considered as the real amount of loss by famine; for not only did the death-rate rise, but the birth-rate fell off materially. The children under ten years of age were in 1901 fewer by 150,000 than they had been ten years before, and the adults over fifty were fewer by 60,000. Between the ages of ten and fifty there was no such large decrease The report says:—

"Excessive mortality among the young, and a high, though less stiking, death-rate among the old, are the inevitable consequences of famine on a large scale."

And yet this great mortality occurred in spite of the most energetic efforts to assist the sufferers. The daily average number of persons relieved in 1899-09 was 265,742, or 9·2 per cent. of the population, and in July 1900 the figures rose to 601,424, or nearly 21 per cent.

The part of India which is the most salient instance of what the effects of famine on the population can be is the Central Provinces, which record not only a heavy actual loss, but also the highest proportional loss of all the administrative units in India. The Census of 1901 records a diminution of 1,071,000 souls, or 8·3 per cent., as compared with that of 1891. The registered death-rate, which had averaged 32 per mille in past years, rose during the famine years to 56 and 69 per mille, while the birth-rate dropped from a mean of 40 to 27 and 30 per mille. In the one good season of 1899 it rose again to 47, and

then in the second failure of 1900 it fell to 32 once more. The Census Report tells us that here, as elsewhere, the chief mortality was among the youngest and the oldest sections of society.

"There can be no question that in 1899-1900 the administration of the Central Provinces was signally successful in keeping alive the large section of the population whose only want was a sufficiency of ordinary food. Children at the breast alone could not be saved; their needs were and always will be of too special and delicate a character to be met by the rough machinery of famine relief."

Bombay is the province which stands highest in respect of the actual decrease of its population. Between 1891 and 1901 it lost a million and a half, or 5 per cent. of its numbers—a startling contrast to the results of the preceding census, which showed an increase of 15 per cent. during the decade. These melancholy figures are the result, not of famine only, but also of plague, which appeared first in Bombay city in 1896, and gradually spread over all the province, causing a heavy mortality, which probably approximates to half a million. But the main cause of the fall in the census numbers was the occurrence of the two famines in 1897 and 1900. During eight years out of the ten, the vital statistics showed an excess of 692,000 births over deaths, but in the years 1897 and 1900 the registered deaths exceeded the births by 92,300. In three of the Gujarat districts the death-rate rose to the enormous rate of 180 to 200 per mille, while the birth-rate fell to less than half the average of the decade. In one district the recorded deaths in 1900 numbered 88,000, or considerably more than in the nine preceding years taken together, and very nearly a third of the population enumerated in 1891.

A part of this mortality was no doubt due to the extensive immigration of famine refugees from neighbouring Native States, who came across the borders in a state of extreme destitution to seek relief in British territory. The chief of these States is Baroda, the conditions of which correspond closely with those of Gujarat. Baroda had enjoyed complete prosperity up to 1899, and the shocking depopulation which has taken place is due entirely to the ravages of that year. The population, which had been counted as 2,415,000 in 1891, fell to 1,952,000 in 1901, a loss of 463,000, or 19 per cent. Greater efforts were made by the official staff of the State to relieve famine than had ever been made before, probably, in any Native State, and yet the results were wholly insufficient.

These statistics show that the mortality resulting from the two famines was more terrible than even the two special commissions which reported on them realised, but they afford no ground for censure of the efforts made to relieve distress, or for crying out against the inevitable. The Census Report is careful to point out that only a small portion of the deaths which occur during a famine is due to actual starvation. A great part is caused by epidemics of cholera occasioned by the collection of a large number of persons in relief works, and the pollution of the scanty water supply. No help can be effectually given to people who refuse to apply for it, and who conceal their wants. Those who know most about the relief measures adopted in India are also those who most admire the energy, the self-devotion, and the zeal of those engaged in the struggle, whether officials or non-officials, whether of the white or coloured races. It cannot be claimed that finality has been reached in these measures. New experience is gained in each famine, and new administrative improvements are introduced. The two great preventive remedies, diversity of occupations and extension of irrigation, must not be lost sight of, and I welcome the recent announcement that the Government of India has sanctioned the construction of a connected scheme of three new great canals in the Punjab which will irrigate about two million acres at the low cost of Rs.40 per acre. But the main conclusion left in the mind by a study of this part of the Census Report is identical with that which has so deeply fashioned the whole train of Hindu thought, the impotence of man before the destructive powers of the elements.

Besides the statistics which I have quoted as to the actual decrease of the population in some parts of India and the check to the natural increase in others, the effects of famine are felt in many ways, and have sunk deep into the social life and condition of the country. I have already referred to the age statistics, which indicate a considerable falling off in the number of children below ten, and a lesser decrease in the number above sixty, these two being the classes among which the pressure of scarcity was most severely felt. In the religious statistics again we find a slight proportional decrease among Hindus and increase among Mohammedans, the explanation

of which is not that there has been any proselytising activity among the Mohammedans, but that the tracts mainly inhabited by them, especially Lower Bengal, Sind, and the Upper Punjab, were not visited by famine, while the area where it was most severe was the stronghold of Hinduism.

The sex statistics tell a similar tale. The proportion of the sexes has always been a perplexing question in India, inasmuch as while in all European countries females outnumber males, in India the reverse is the case, and the recent census shows that there are only on an average 963 females to 1,000 males. The fact that the disproportion varies greatly in different parts adds to the perplexity of the case. In the Central Provinces and Madras the females are in excess, the enumeration showing 1,031 and 1,025 females respectively to 1,000 males; in Bengal the numbers are almost equal; on the other hand, in Kashmir and the Punjab they fall below 900 females to 1,000 males.

But while the average number of women to 1,000 males was 963 in 1901, it was only 958 in 1891, an increase of five women to every thousand men. This relative increase in the number of women during the last decade appears to be closely connected with the prevalence of scarcity and famine. In the parts of Bengal where there was a good deal of scarcity, Bihar and Chota Nagpur, the ratio of women to men has risen. In the Central Provinces, where there was the greatest pressure of famine, the relative increase of the female sex has been greatest of all, and in the United Provinces, Bombay, Baroda and Rajputana, all of which suffered severely, the same result is very noticeable. All the authorities seem agreed in holding that women succumb to famine less easily than men; and the diminution of the birth-rate, with the lessened risk of life from parturition, also tends in the same direction.

A further instance of the working of the same far-reaching cause is to be found in the enumeration of the sufferers from four classes of infirmity—the insane, deaf, blind, and lepers.

	1891.	1901.
Insane	74,279	66,205
Deaf	196,861	153,168
Blind	458,868	354,104
Leper	126,244	97,340
Total	856,252	670,817

Other causes have no doubt co-operated in producing this reduction, such as greater accuracy of diagnosis, improved sanitation, and the larger amount of relief procurable in hospitals and dispensaries. In the case of the blind, too, a special cause has been at work; for there is no operation performed by English surgeons in which the people of India have greater confidence than the operation for cataract. They flock to our hospitals to obtain this relief, and during the last ten years 146,000 persons have by its means recovered their sight. But, putting this aside, the main and most general cause of the diminution in the numbers of those afflicted with these infirmities was undoubtedly the famines, which fell with especial severity on those who generally live by begging, and who are less capable of succeeding in the struggle for life than the mass of the population. The insane and the leper are the two classes which would naturally suffer most; the insanes because they are seldom able to apply for help, and the lepers because they are almost always outcasts possessed of no stores or resources.

Leprosy is a disease which specially arrests attention, on account of its loathsome character and its former prevalence in Europe, and the Report records a decrease in its figures from 56 per 100,000 in 1881 to 33 now. The Leprosy Commission of 1890 reported that the disease is not due to hereditary transmission or to contagion, but originates *de novo* in each case, and that it cannot be connected with any geological conditions nor to temperature or climate, nor yet to any class of food. Nothing has since transpired to increase our knowledge of the question, nor do the census statistics throw any fresh light on the subject. All that they do is to enable us to prepare maps illustrating the areas where the disease is most prevalent, but these areas seem to have nothing in common. In certain districts in West Bengal, centering in Bankura, it is twice as prevalent as in any other part of India; then comes the Goalpara District of Assam, then West Berar, then a tract along the southern face of the Himalayas. The physical and climatic characteristics of these tracts differ as widely as do the races who inhabit them and their food supply. No bacillus causing or associated with leprosy has yet been fouud. The old hypothesis that it may be connected with eating imperfectly cured fish, recently revived by Mr. Jonathan Hutchinson, finds no support in the census statistics. Where science has discovered so much, there is no reason to despair of ultimate success in laying bare the causation of this horrible disease,

and we may hope that the historian of the next census will have some new light to throw on it.

The last instance I have to give of the influence of the famine on the movement of the population, though in this case the influence is more distant and indirect, is the progress of Christianity. The number of Christian natives in India, which was 1¼ millions in 1872, is now 2⅞ millions. Of these two-thirds, or about 1,700,000 are Roman Catholic or Syrians, mostly descendants of the converts made some three centuries ago by St. Xavier and others in Southern India. The Protestant or Reformed Churches number about 850,000, or one-third of the whole, and they are mostly the product of missionary enterprise during the latter half of the last century. During the last decade they have increased over the whole of India by 75 per cent., but in several provinces the progress has been even more striking. Their numbers have trebled in the United Provinces and Central Provinces, and they have doubled, or more than doubled, in the Punjab and Assam.

The Census Report deals with admirable fairness and sympathy with this question of the evangelisation of India. The influences which combine to favour the spread of Christianity are discussed, and it is admitted that the motives for conversion are not always wholly spiritual, but it is shown that the charge that many change their religion merely from hopes of material gain is refuted by the mere largeness of the numbers, as it would be impossible for the missionary bodies with their scanty resources to contribute materially towards the support of many converts. That conversions are most frequent among the lower castes of Hindus is easily explained by the fact that among them philosophic doubts and social disabilities have not much weight, and by the advancement in education and social position which Christianity offers. In the case of the aboriginal tribes of Chota Nagpur the movement toward Christianity has been largely influenced by practical considerations. "They look to missionaries for help in their disputes with their landlords, and they see in Christianity a means of escape from the payment of fines imposed on witches and on those who are supposed to have neglected the demons, and from the persecution to which they would be subjected if unwilling to meet the demands of the *Bhuts* (spirits) and their earthly servants." In many provinces the results of famine have been to fill orphanages with waifs and deserted children, who are brought up as Christians. Thus in the Central Provinces the number of converts belonging to Protestant Missions has risen, since 1891, from 1,000 to 10,000; in Bombay from 5,000 to 33,000; and in Baroda, where there were only 41 converts in 1891, there are now over 7,000.

A curious sidelight is thrown on the missionary question by comparing the number of natives who have been converted to Christianity with the number who have been taught English. I omit provinces like Madras in which Christianity has become hereditary, and taking only those in which the conversions date mainly from the last two generations, Assam, Bengal, United Provinces, Punjab, Bombay, I find that the census records 727,000 people as English literates. Unfortunately it did not distinguish the English and Europeans who learn English instinctively, at home, as a mother tongue, from the natives who learn it educationally, at school, as a foreign language; but the previous census did make this distinction, and the number of natives was then found to be three-quarters of the whole. Assuming the same proportion to exist now, the number of English literates among the native population of the provinces I have named is 550,000. The number of native Christians in the same provinces is 487,000, which is not much less. When we consider the nature of the influences engaged in either case—on the one hand, the zeal of the missionaries, isolated individuals for the most part, with no official position, and very exiguous funds; on the other hand, the efforts of the education officers, with large supplies of money and the prestige of Government behind them; on the one hand, the sacrifice of family ties and old associations which conversion entails, on the other hand, the prospect of Government service or at least of well-paid and comfortable employment which an English education promises—it is wonderful to find that the successes of the Gospel come so close, numerically, to those of the Government department.

Before leaving this branch of my subject, I cannot refrain from quoting an interesting passage in Mr. Rose's report on the Punjab census, which gives an account of a sect called the Chet Ramis, after one Chet Ram, who died about thirty-five years ago. He was a man of little education, the son of a moneylender in the Lahore district, and he began his mission when about twenty-five years of age. The chief basis of his teaching was implicit confi-

dence in Christ as the only God. A copy of the Bible was to be worn by each of his disciples round his neck, and they were to carry a long rod with a cross at its head, with the following inscription:—"Help, O Jesus Christ, Holy Ghost, God. Read the Bible and the Gospels for salvation." The sect has largely increased in numbers since the census of 1891, when it was little known, and was supposed to be purely atheistic. This story is remarkable as one of many proofs that the doctrines of Christianity have sunk deeper into the conscience of the people of India than the mere numbers of conversions indicate.

I turn now from those parts of the Census Report which deal with the movement of the population—the dynamic portion—to those which depict its actual condition—the static part—but I have only time to touch, and that too briefly, on the three chapters on language, marriage, and caste. These are the most valuable part of the report from the scientific point of view, and they are written by the two men who are the greatest living experts on these subjects—Dr. Grierson and Mr. Risley. Dr. Grierson has for the last eight or nine years been employed by the Government of India on a linguistic survey, or exploration, of the languages spoken in the northern and central parts of India, and his task is, I believe, nearly finished. He divides the 147 vernacular tongues enumerated in the census into three main families—the Dravidian, spoken by the aboriginal population; the Indo-Chinese, spoken by invaders from the N.E.; and the Indo-European by invaders from the N.W. The complexity and elaborateness of many of the Dravidian and Indo-Chinese tongues is hardly conceivable. For instance, in the Santhali language, the conjugation of the verb "to strike" occupies 100 pages of Mr. Skrefrud's grammar. In some languages the verb has no passive voice, only an affirmative and negative voice. No Tibeto-Burman language has a verb at all; for "I go" they say "my going." In some cases we find agglutinative tongues beginning to isolate their monosyllables—in some, phonetic attrition is turning dissyllables into monosyllables, and so the process of endless change continues. Dr. Grierson writes:—

There are languages whose phonetic rules prohibit the existence of more than a few hundred words, which cannot express what to us are the commonest and most simple ideas; and there are others with opulent vocabularies, rivalling English in their copiousness and in their accuracy of idea-connotation. There are languages, every word of which must be a monosyllable, and others in which syllable is piled on syllable till the word is almost a sentence by itself. There are languages which know neither noun nor verb, and whose only grammatical feature is syntax, and others with grammatical systems as complicated as those of Greek and Latin. . . . There are parts of India which recall the plain in the land of Shinar, where the tower of old was built, and in which almost each of the many mountains has its own language, and there are great plains, tens of thousands of miles in area, over which one language is spoken from end to end.

The main group of languages, spoken by 221 millions of India belongs to the Indo-European family. The origin of the races which compose this family has been placed in various localities; first the mountains of the Caucasus or the Hindu-Kush, then in North-Western Europe on the shores of the Baltic, then in Armenia and Northern Persia; and, lastly, Dr. Grierson seems disposed to agree in the view which locates their domicile on the borderland of Asia and Europe, the steppe-country of Southern Russia. Here, he tells us, they broke into two divisions. The first, who, in speaking of the number 100, used a word similar to the Latin word *centum*, turned westwards and became the parents of the Greek, Latin, Keltic and Teutonic races. The second, who described the same numeral by the Sanscrit word *sat*, wandered to the East, and from their speech descended the languages known as Aryan, Armenian, Phrygian and others. It is with the Aryan sub-family of the Indo-European family that we are concerned at present. Leaving the common home, they probably took their way north of the Caspian and settled in the oasis of Khiva for a time; and then dividing again, one branch went westward to Merv and Persia, one crossed the Hindu-Kush and entered India by way of Cabul, and settled in the Punjab. But this settlement did not take place all at once, but gradually, and Dr. Grierson holds that that there was a distinct and important later invasion which penetrated like a wedge into the country already occupied by the first immigrants, forcing them outward and backward in the north, south, and west directions, and pressing on itself into the "middle land" of Aryan tradition, the Valley of the Ganges and Jumna.

We have all been brought up to believe in this doctrine of the Aryan invasion from the North-West, and we have often, no doubt, found it hard to realise how such

an immigration was carried across deserts and mountains which even a Russian army with railways and transport organisation would find it hard to traverse; especially if we are to believe they did succeed in bringing their women with them, so as not to be reduced to the necessity of capturing Dravidian brides. Mr. Risley's solution of these questions is an ingenious one. He produces evidence from history and physical geography that the desert plains of South-Eastern Persia and the dreary steppes of Central Asia were once a fertile, populous and well-cultivated tract; but in process of time the climate changed, the forests were cut down, rainfall diminished, the level alluvial tracts lapsed into desert, and the population, as they began to press on their own means of subsistence, or were pushed forward by incursions from the West, moved by tribes or families as an organised society and occupied the valley of the Indus. This movement must have lasted over many centuries, and when the process was completed and the country behind was turned into a waterless desert, haunted by robbers, later invaders could only enter by force of arms, bringing hardly any women with them. Then the second Aryan invasion, traced by Dr. Grierson's linguistic researches, pushed on through the country occupied by the first Indo-Aryans into the valley of the Ganges and Jumna, where they came in contact with the Dravidians and produced the Aryo-Dravidian race which is now established there. "Here from the stress of this contact, caste was evolved; here the Vedas was composed, and the whole fantastic structure of orthodox ritual and usage was built up."

Mr. Risley's researches into the origin and characteristics of caste have been largely helped by the ethnographic survey which he started tentatively in 1890, and which is now being carried out on a comprehensive scheme under Lord Curzon's order. The measurements taken are those of the length and breadth of the skull, the height and breadth of the nose, and the stature, these being accepted as the most persistent indications of difference in blood and race. India, with its strict rules as to marriage, is a peculiarly favourable field for this method of investigation. In a society putting an extravagant value on pride of blood and the idea of ceremonial purity, difference of physical type, however produced in the first instance, may be expected to manifest a high degree of persistence. Mr. Risley tells us that the longest heads, the tallest stature, and the highest noses, are found in the Punjab, and there is a progressive decline in height and increase in breadth of head and nose down the valley of the Ganges to Bengal, and to the south.

He adds that the relations of the nasal index to the social position of the caste are remarkable. If we take a series of castes in Bengal, Bihar, the United Provinces of Agra and Oudh, or Madras, and arrange them in the order of the average nasal index, so that the caste with the finest nose shall be at the top, and that with the coarsest at the bottom of the list, it will be found that this order substantially corresponds with the accepted order of social precedence.

When the census officer attempts to lay down a scheme for the classification and enumeration of castes, he is met by great and unexpected difficulties. Mr. Risley defines caste as a collection of families bearing a common name which is usually associated with a specific occupation, claiming common descent from a mythical ancestor, and forming a single homogeneous community. No member of a caste can marry outside his caste; and it usually contains a number of smaller circles within which marriage is confined. It is the marriage law which forms the essential distinction of caste; the rules regarding food and drink naturally come first to the notice of the superficial observer, and have been held to be the special peculiarity of caste-observance; but they are comparatively fluid and transitory, whereas the marriage-regulations are permanent.

But while this definition of caste seems to confer on it an iron-bound, immutable character, it is, in fact, an institution in a state of continual flux and variation, subject to the influences of rise and fall of social condition and subdivision of occupation. Tribes have been and are still being converted into castes; changes of occupation bring about the formation of separate sub-castes; religious sects when they become numerous re-organise themselves on the lines of a regular caste, and create for themselves rules for the restriction of marriage limits; new castes are formed from the offspring of irregular sexual relations, and from the migration of a party from the headquarters of their caste to a distant place, which subjects them to the suspicion of having departed from the original strictness of regulations, and tends

to break the *jus connubii*, and so separates them from the parent stock. Many interesting and curious examples are given in the report of these processes which are constantly going on under the eyes of our Indian administrators, but space will only allow of quoting one of them. Referring to the way in which aboriginal tribes, having risen in the world and become landed proprietors, get themselves enrolled, by some mythical assumption, generally connected with a miracle, in one of the more distinguished castes, Mr. Risley writes:—

"The most picturesque instance of the class of legend to which I refer is that associated with the family of the Maharajas of Chota Nagpur, who call themselves Nagbansi Rajputs, and on the strength of this mythical pedigree have succeeded in obtaining wives of reputed Rajput blood. The story itself is a variant of the well-known Lohengrin legend. It tells how a king of the Nagas, or Snakes — the strange prehistoric race which figures so largely in Indian mythology—took upon himself human form and married a beautiful Brahman girl of Benares. His incarnation, however, was in two respects incomplete, for he could not get rid of his forked tongue and evil-smelling breath. In order to conceal these disagreeable peculiarities he always slept with his back to his wife. His precautions, however, were unsuccessful, for she discovered what he sought to conceal, and her curiosity was greatly inflamed. But the Snake King, being bound by the same conditions as his Teutonic prototype, could only disclose his origin at the cost of separation from his wife. Accordingly, he diverted her attention by proposing to take her on a pilgrimage to Juggurnath. Their route lay through Chota Nagpur, and when they reached the neighbourhood of Ranchi the wife was seized with the pains of child-birth, her curiosity revived, and she began to ask questions. By folk-lore etiquette questions asked at such a time must be answered, and her husband was compelled to explain that he was really the Takshak, King of the Snakes. Having disclosed the fatal secret, he straightway turned into a gigantic cobra, whereupon his wife was delivered of a male child and died. The poor snake made the best of the trying position in which he found himself; he spread his hood and sheltered the infant from the rays of the midday sun. While he was thus occupied some wood-cutters of the Munda tribe appeared on the scene and decided that a child discovered in such remarkable circumstances must be destined to a great future and deserved to be recognised as the Raja of the tribe. This is the family legend of the Nagbansi (or snake-child) Rajas of Chota Nagpur."

This description of the fluid and fissiparous character of the institution explains the difficulty of establishing any sound classification of castes. As Mr. Risley observes, in a country where the accident of birth determines the whole course of a man's social and domestic relations, and he must eat, drink, dress, and marry in accordance with the usages of the community into which he is born, one would suppose that the question to what caste he belongs is one which he would answer with certainty and precision. If he belongs to a well-known tribe or caste this is the case, but if he belongs to an obscure, isolated, or newly-formed caste he may give the name of a sect, a sub-caste, an exogamous sept, or may describe himself by his occupation or the tract of country from which he comes. To reconcile all these various titles and to co-ordinate them under the head to which they really belong, is impossible. The principle adopted in the recent census was to accept the names as given and to classify them according to their social precedence as established by the facts:—

"That Brahmans of high-standing will take water from certain castes, or will serve certain castes; that some castes, though not served by the best Brahmans have got Brahmans of their own; that some are not served by Brahmans at all, but have priests of their own; that the status of some castes has been raised by their taking to infant marriage, or abandoning the re-marriage of widows . . . . that some can claim the services of the village barber and some cannot; that some may not enter the courtyard of certain temples, or must not use the village well, or may draw water only with their own vessels, or must live outside the village or in a separate quarter, or must leave the road on the approach of a high caste man, or must call out to give warning of their approach."

The classification, made on this principle, was drawn up in each province in consultation with its own experts and representative men, and the names and numbers of the different castes in each province, arranged in from four to seven or eight classes, will be found in the Report by those who wish to study the subject more deeply.

The last subject on which I can touch to day is that of marriage, and there are few things more curious than the laws which govern marriage in India and the anomalies which some of these produce. It is generally known that the rules about prohibited degrees are strict: there are classes into which a man must marry and sub-classes into which he must not marry. Every Brahman must marry a Brahman, every Rajpoot a Rajpoot, and so on; but there are ten main subdivisions of Brahmans and thirty-six royal clans of Rajpoots, and no one may marry into his own subdivision

or clan. These rules seem on the whole to have sprung from wise experience; they secure community of blood and manners, while they avoid the danger of close breeding in and in.

But there is another law to which Mr. Risley claims to be the first to draw the attention of ethnologists, and which he calls the law of hypergamy. You must marry your daughter to a clan or subdivision above you; for your son you may take a daughter from a clan below you. This often leads to difficulties. Suppose the Rajpoot clans to be arranged in order of precedence from A to Z. Then it is easy to for B to give his daughter to A and to take a daughter for his son from C. But what are A and Z to do, with no one above them or below them? The custom of female infanticide among the higher classes sprang largely from this difficulty, as they would not acknowledge any clan higher than themselves.

Readers of Tod's "Rajasthan" will remember the romantic story of the Princess of Udaipur who was wooed by her only two possible suitors, Princes of Jaipur and Jodhpur, and how to save those two great clans from a destructive war she nobly devoted herself to death. A more modern effect of the same system is the custom known in Bengal as Kulinism, under which a single Brahman of very high rank marries 50 or 100 girls of a sub-caste just inferior to his own—a custom which one is glad to see the Census Report declares to be dying out.

What was the origin of this curious practice? No explanation is given of it in any vernacular works, and Mr. Risley declares that it has escaped the notice of all modern writers on the early history of marriage. The only suggestion that he can make is that it may have risen from the invasion of a conquering race who might naturally take wives or concubines from among the conquered, though they would not give their daughters to them. From this origin it might "extend itself by the operation of imitative fixtures to the connubial relations of all classes not absolutely equal in rank."

This explanation is simplicity itself compared with the difficulty of accounting for another custom, that of infant marriage, which, according to Mr. Risley, is steadily increasing, and has almost displaced adult marriage among the higher castes, insomuch that in 1901 16 per cent. of the female population or 2,000,000 girls were found to be married and below the age of ten. What, he asks, induced people already practising a rational system of adult marriage to abandon it in favour of a rigid and complicated system of infant marriage? Among lower castes it has been consciously borrowed from the higher castes by that tendency to imitation which we may almost describe as an ultimate law of the caste system. But how did the higher castes come by a custom which is without parallel, at any rate on so large a scale, elsewhere in the world, and which cannot be referred to any of those primitive instincts which have usually determined the relations of the sexes? Neither sexual passion nor the desire for companionship and service can account for a man marrying a girl when she is physically incapable of fulfilling any of the duties of a wife.

The prohibition of widow re-marriage is not so widely spread as the custom of infant marriage, and its possible origins are not so hard to find, but still it offends against natural instincts, and where the number of the female sex falls short of the males, it must create great inconvenience. Several causes are alleged in explanation, though none are fully satisfactory, and one which sets out that among the higher castes the difficulty of finding husbands for their girls is great, and would be greater if widows could compete, is a sentiment which, as Mr. Risley remarks, smacks strongly of the philosophy of Mr. Weller, senior. As long as this is the attitude of the higher castes, the lower castes will be more and more drawn to follow it, through the strong tendency to imitation. The Hindu mind has a passion for ceremonial purity, and takes a pleasure in giving up practices it delights in, if they are opposed to the ascetic rule and to the practice of Brahminical caste. Mr. Risley acutely remarks that, contrary to general expectation, the strength of the Hinduising movement has been greatly augmented by the improvement of communications. "Railways, which are sometimes represented as a solvent of caste prejudices, have enormously extended the area within which caste prejudices reign supreme." It is to be feared that the efforts of the few leaders of native society who are affected by English thought and standards will have a harder struggle than ever against the spread of prohibitions which have such a strange attraction for the people of India.

I should have liked to have added a few remarks on some of Mr. Risley's interesting speculations on the origins of religious ideas, based on his unrivalled knowledge of the pro-

cess of thought in aboriginal minds, but time does not permit, and I must close a paper which is I fear already too long.

Lord Curzon, in his speech on July 20th, last year, at the Mansion House, paid a tribute to the great administrative ability of the members of the Indian Civil Service, whom he described as the "organisers of victory." This Census Report is in a high degree evidence of these qualities. I have written in vain if this audience have failed to appreciate the organising talent shown in the planning of the census operations, the administrative ability which trained and disciplined the vast body of men employed in carrying them out, and the literary and scientific power shown in marshalling these results and drawing out the conclusions to be deduced from them. I have only gleaned a little from the fair crops of administrative wisdom, religious legend, ethnic myth, and philosophic speculation to be found in the report, but I trust I have said enough to show the immense field it covers, and the sterling value of the contributions made to our knowledge of India by Mr. Risley, Dr. Grierson, and Mr. Gait.

DISCUSSION.

Mr. J. A. BAINES, C.S.I., said that if there had been any material difference between his views on the subjects dealt with and those of the author he would be diffident in expressing it since he had the most agreeable and grateful remembrance of the way in which his tottering footsteps in census-taking were guided by Sir Charles Elliott, to whom, as first Census Commissioner, much of the success of the operations had been due. Each census was more accurate than its predecessor, but the foundations had been laid soundly at the outset. He could only deal with one or two of the many interesting points contained in the very comprehensive paper before them. In the first place, it was important to recognise, as the author had done, the two aspects in which the census should be regarded. The complications of Indian civilisation entailed a knowledge of the statical side, though he was of opinion that ethnology might be better treated by an expert once for all, and his work given as a reference by census reporters, and thus save the introduction of much discussion of "origins." As he had been himself a sinner in this respect, he would say how grateful he was for the confirmation in 1901 of views he had put forth tentatively ten years before, as to the routes and succession of the Aryan occupation of Upper India. On this, the evidence of Dr. Grierson, was, he thought, conclusive. Again, he welcomed the importance given to the desiccation of the regions bordering India to the north-west in the ethnology of that country, since, by this process, the Aryans had been cut off (in course of time) from their racial base, and left to develop their civilisation on independent and unique lines. In the dynamic aspect of the census he was inclined to include the movements of language and religion. The former, as admirably analysed by Dr. Grierson, tended to restrict the linguistic differences amongst the hill tribes, whilst the actual population was increasing. Much the same might be said of the tribal forms of religion, under Brahmanic pressure. He would call attention, in connection with this matter, to the difference in its social results of a change to one of the non-Indian religions, such as Christianity or Islam, from absorption of tribes into the Brahmanic fold, or change of sectarian doctrine inside that sphere. The latter kept the convert as he was in social position, provided only doctrine was touched, and sects of this sort were, therefore, largely recruited from the upper classes. But modification of ceremonial or social rank involved the creation of a separate community, and was favoured, accordingly mostly, if not solely, by those who had little position in society to lose or gain by the change. In conclusion, he expressed the great pleasure he felt in finding that the first Census Commissioner for India had so long retained his interest in that important subject.

Dr. G. GRIERSON, C.I.E., said he only wished to refer to the use, in the Census Report, of the word "Dravidian." When the linguistic chapter of the census was written the Linguistic Survey of India had not reached the Dravidian languages, and what was written then was written on the knowledge that was generally held by people in those days. Since then things had considerably altered. Owing to the progress made by the Linguistic Survey, the Dravidian languages had been analysed and examined, and some remarkable discoveries had been made. There were in India proper, roughly speaking, three families of languages—the Aryan in the north, the Munda in the hills of the centre, and the Dravidian in the south, and also in Baluchistan. When Mr. Risley made the most important discovery, during his ethnographical enquiries in Bengal, that the Mundas and the Dravidians had an identical ethnographic type, that was to say, they had the same nasal index and the same size of head, and so on, the fact was accepted as quite natural, because it was very generally thought that the Munda and the Dravidian languages, though very different at the present day, had a common origin; but he thought when the results of the Linguistic Survey regarding them were published no one would be able to deny that the origin of the Munda languages and the origin of the Dravidian languages must be taken as entirely separate. They were not the same, or had not been, at any rate, this side ot the Tower of Babel. They were different in phon-

ology, different in method of making up words, different in syntax, and different in every particular which is of importance for philological classification. Basing his nomenclature on the fact that both the tribes who spoke Munda languages and those who spoke Dravidian languages had the same physical type, Mr. Risley had called that type "Dravidian," and in the ethnographical portions of the Census Report the word was used in this extended sense. But the application of the name to two families of people speaking two distinct and very different languages, although having exactly the same physical characteristics, would give rise to confusion, because Mr. Risley's Dravidian physical type would, on the other hand, include many millions of people who did not speak the Linguistic Survey's Dravidian languages, while, on the other hand, the speakers of the Linguistic Survey's Dravidian languages would include the speakers of Brahmi in Baluchistan, who have not Mr. Risley's Dravidian type. He himself thought that what Mr. Risley called Dravidian should be called by some other name. It seemed an injudicious thing for a linguist to do, but he would like to make a suggestion as to how it was possible that the Dravidians of Southern India had the same ethnic type as the Mundas. He only gave it as a suggestion. They all knew how the Aryans, as they moved eastwards from the Punjab down the Ganges Valley, became more and more aboriginalised, and so in the east of Bengal there were now so-called Aryan tribes who had all the characteristics of the aborigines, flat noses, curly hair, and so on, and yet they had retained the Aryan language. That was the important point. The Aryans had retained their language, but altered their physical type. Why was not the same thing possible with the Dravidians? If they came in from the north-west, say through Baluchistan, and went down south, they would retain their language as the Aryans had done, and by mixing with the aboriginal Mundas they would naturally acquire the physical type of that ethnological family.

Mr. J. D. Rees, C.I.E., said they must all congratulate themselves on the fact that a gentleman of the author's position and ability had undertaken the task of popularising some of the results of the census which were buried in the Blue-books on the subject. Few people had undertaken the task—he had tried to do so in one of the Reviews—and it was most regrettable that a report that was so replete with interesting information should be practically closed to the British public. The author had referred to the condition of the poor, and the serious results of the last famine in decreasing the population. He thought some misunderstanding was likely to result if one looked only at the ordinary accounts of the famine, but that misunderstanding would soon be dissipated on a perusal of the Blue-book. There was a larger proportion of people in receipt of relief at the expense of the State in England in a normal year than there was in India during the height of the famine. The author had referred lightly to the question of leprosy in India. Mr. Hutchinson had been preaching that the prevalence of leprosy in India was due to the use of imperfectly cured fish; but the author pointed out that that was flatly contradicted by all the authorities who had been appointed on the subject. As to caste and the progress of Christianity, he thought it would be well to guard themselves against thinking that the large increase in actual numbers of Christians in India went to prove that caste and Hinduism were in anyway relaxing their hold upon the people. In fact, Mr. Risley himself pointed out in the Census Report that the railways, which had been spoken of as the breakers down of caste, practically led to its greater strength. He could confirm that himself from his experience as a director of the South Indian Railway. As soon as a railway was opened, the number of pilgrims to the great temples in the south enormously increased, and yet in that very room he had heard not long since a distinguished gentleman from India point out that caste was the curse of the people of India, and that it was, to his great joy, disappearing and diminishing in strength every day. They had in the Census Report an exact contradiction of that statement, upon the highest authority after the most careful and comprehensive examination.

Mr. F. H. Skrine said that he had listened to Sir Charles Elliott's story of the Indian Census with the deepest interest because, like many of his colleagues who were present, he had taken an active part in these decennial numberings of the people. In 1871 the authorities were confronted by a universal suspicion that the census was a prelude to some form of taxation. Thus the unhappy enumerators met with refusals and evasion on all sides; and many returns were evolved from their own inner consciousness. This attitude of the population at large served to explain the shortage of women in the returns. The disproportion between the sexes was, probably, no greater in India than elsewhere; but indulgence in polygamy was an outward and visible sign of wealth: and in the old Mughal days an appearance of wealth was sure to attract the attention of the tax-gatherer. The most important point made in the "dynamic" section of the paper was the light it cast on the working of Malthusian doctrines. It was clear that some, at least, of the checks on over-population enumerated by Malthus were coming into play; and that Government was powerless to protect the masses from the result of their ingrained improvidence, resting as it did on religious sanctions. Turning to the static portion of the paper, he agreed with Mr. Baines in thinking that excessive attention was given in the Census Reports to ethnological speculation. The origin and migrations of the human race were too complicated and obscure for treatment in official reports. It would baffle the eru-

dition of Dr. Grierson to explain why the Finns, Magyars, and Basques spoke an agglutinative tongue which had close affinities with the Dravidian languages of Southern India. He was at one with the author as to the vast influence of railways and steam navigation in developing the caste system and increasing religious sentiment. By enabling the poorest Indian to revive his flagging faith at the centres of pilgrimage, they had given new life to every creed. Taken as a whole, the paper was worthy of its subject, and that was saying a good deal. The evolution of the census, in the teeth of widespread apathy, ignorance, and suspicion, ranked foremost among the many triumphs of British administration in India.

Mr. MARTIN WOOD said he wished to make just one remark on what Mr. Baines had spoken of as the dynamics of the subject—the normal increase of the population, or abnormal shrinkage of its growth. This consideration was necessarily dealt with in the more serious passages of Sir Charles Elliott's valuable paper. For his part he thought that the chief means of preventing famine, or lessening its intensity, was to wage war against drought. There was not, as far as he could see, a single water-work erected in those districts which had suffered most—as mentioned in the paper, British Guzerat, Central Provinces, and the Deccan—whereas an enormous work had been designed and accepted in the east of the Punjab, a district which had not suffered much from the famine. He did not think it was right that local works which were most urgently required should be neglected.

Sir CHARLES ELLIOTT said he did not purpose at that late hour to enter into any of the questions raised in the discussion, except as to the criticism that too much had been said in the Census Report dealing with ethnology, origins of religions, &c. He thought there was a considerable amount of truth in that criticism, but he would point out that in ten years' time they might not have another Census Commissioner of the same gifts with regard to those topics as Mr. Risley. In the course of a census an officer was brought into close contact with those questions, and had time to go into them thoroughly; and if he had a strong natural turn for such subjects, it was practically impossible for him not to put them before the public in the shape of an official report.

On the motion of the CHAIRMAN, a hearty vote of thanks was accorded to the author for his exceedingly interesting paper.

Mr. BAINES writes:—Having dwelt overlong on the ethnographic side of the paper, I was prevented from commenting upon the figures quoted. There is one point, however, which, in case it was not noticed by those who spoke after I left, I should like to mention, viz., the rate of growth of the population. For the reasons given by Sir Charles Elliott, the bare totals, even when qualified by the deductions he makes, are not accurate indications of the rate of increase under really normal conditions, *i.e.*, ten years without severe famine or a continued series of unusually favourable seasons. We have to trust, therefore, to the age returns, not in their crude form, but after actuarial treatment. It appears from these that a remarkably high birth-rate, due in great measure to the universality and early age of marriage, is greatly neutralised by a high death-rate, especially amongst infants, which, in India, as in most other countries of the Old World, is the usual accompaniment of great prolificity amongst the masses. We find, moreover, that life in India is considerably shorter than in temperate regions. Thus, the average rate of increase established by the comparison of the figures of the three enumerations comes out a little below 1 per cent. per annum. With the spread of medical aid and trained midwifery this may be slightly raised, but otherwise, in the conditions of Indian industry now subsisting, and likely to continue for some time to come, the above rate is probably as high as the country can support without an economic change for the worse; because the whole burden of the increase being practically borne by the soil, a larger share of the cultivated area would have to be directly devoted to the production of the means of subsistence, instead of, as now, providing an important reserve of raw, non-food, material for foreign export, through which the ryot makes his profit, and the country at large pays for its administration.

SIR RICHARD TEMPLE writes:—I regret that I was obliged to leave the meeting at which Sir Charles Elliott drew attention to a few of the conclusions to be drawn from the Indian Census Report of 1901 before I could be called upon to speak. The point in his paper which I may be able to illustrate from my own experience is that relating to the very important —all-important I might almost say in view of possible developments owing to British administration—subject of the birth and development of caste. It fell to me to write Vol. III. of the Provincial Census Reports for 1901—the Andamans and Nicobars—and among the populations I had to deal with were the descendants of the Hindu convicts sent to Port Blair. The preservation of caste among a population so unfavourably situated for such a system much interested me, and I made all inquiry into the subject possible to me in view of the census. Practically, I found the marriage system to be the one criterion of "caste"—a conclusion arrived at by most experienced observers. Among the convicts the situation is this, male and female convicts have, ever since the foundation of the penal settlement, about fifty years ago, been allowed to marry under certain strict administrative rules. But it will be understood that though the general rule in the Hindu caste marriage customs—caste to caste,

i.e., Brahman to Brahman, Rajput to Rajput, and so on—could be carried out in these marriages, the local customs which obtain within the general castes were impossible. That is, the Bengal Brahman would have to be satisfied with a Brahmani from Madras, a Rajput from Kachh with the daughter of a Rajput from the Himalayas. In all such cases the *jus connubii* would in India be held to have been broken, just as it has been broken all over India by migrations of colonies from the headquarters of castes. Therefore, in all such cases, the children would not be recognised as fellow castemen in India by the castes to which they claimed to belong. The interesting and ethnologically valuable question then is: How do the descendants of such marriages behave in the circumstances? Have they degenerated from the parent castes? Or are they preparing to maintain the caste system? The answer was quite clear on enquiry; the caste system will be maintained among these people in all its integrity locally, just as it has been maintained locally by emigrants cut off from the parent stock. This question being so answered, the next and most informing question is: How are they managing it? The great difficulty was the supply of brides of equal caste. For the handing on of absolute purity of blood it proved insuperable. There were not in the second generation locally procurable Brahman girls for all the Brahman boys, or what is perhaps of more consequence in this case, Brahman boys for all the Brahman girls at the appropriate and indeed obligatory time for marriage, and so on for all castes. This hard knot was cut thus. It was held that what really mattered was the caste of the father, that the mother (or bride) became merged in her husband's caste on marriage, and that all children were of the caste of the father. In this way, sisters became on marriage to be actually of separate castes, and first cousins to belong to different castes. The great point, however, was that locally the castes were retained in their fulness of distinction, however little it was possible to retain purity of blood in the initial stages. The next point to be noticed was that though frequently obliged to maintain caste in this irregular way, by pressure of environment, there was a never relaxed attempt as the time for children's marriage came on, to adhere to the principle of caste to caste. As this population increases, and it must rapidly do in a land where nearly all the children born are reared, no doubt this principle will gradually override that of ignoring the bride's caste, adopted as it has been, of necessity and obviously not of choice. The Census Reports of the future will show. In my report, I collected all the information and statistics available, but I was too close to the "birth" of a new caste system to collect details in sufficient quantity to prove the tendency noted. Of course, in India the Port Blair castes will not be recognised, but that is of no practical consequence as all recognition of caste is a local affair.

TWELFTH ORDINARY MEETING.

Wednesday, March 1, 1905; SIR EDWARD POYNTER, Bart., P.R.A., in the chair.

The following candidates were proposed for election as members of the Society:—

Aldwyncle, H. J., P.O. Box 5596, Howard-buildings, Johannesburg, Transvaal, South Africa.
Biliotti, Frank, 8, John-street, Adelphi, W.C.
Bracher, Mrs. L. E., Hamilton, Waikato, New Zealand.
Cooper, William James, A.M.I.Mech.E., A.M.I.E.E., 15A, Turnpike-lane, Hornsey, N.
Crawford, William, J.P., Mount Randal, Belfast, Ireland.
Dawson, David Stewart, 20, Hatton-garden, W.C., and Hotel Cecil, Strand, W.C.
De Landero, Carlos F., Apartado 3, Pachuca, Mexico.
Denny, Harry S., P.O. Box 4181, Johannesburg, Transvaal, South Africa.
Fawcett, Francis Thomas, 135, Nag's Head-road, Ponder's End, Middlesex.
Flannery, Sir J. Fortescue, Bart., M.P., 9, Fenchurch-street, E.C.
Hadaway, William Snelling, Penrhyn-cottage, Bushey, Herts.
Hughes, F. G., Salisbury, Rhodesia, South Africa.
Hutson, Alfred Robert, 123, Darnley-road, Gravesend.
Mitchell, W. F., 26, Craven-hill-gardens, W.
Samuel, S., 11, Portland-place, W.
Smith, W. Ramsay, D.Sc., M.B., Winchester-street, East Adelaide, South Australia.
Sumner, Orlando, Dalry-house, Ashton-on-Ribble, Lancs.

The following candidates were ballotted for and duly elected members of the Society.—

Barratt, Reginald, A.R.W.S., Arts Club, 40, Dover-street, Piccadilly, W.
Beckett, Henry Barron, Mailla, The Green, Wimbledon.
Bertram, Henry, 1*a*, Cooks-road, Stratford, E.
Bonnett, Charles, Messrs. F. and C. Osler, Hornby-road, Bombay, India.
Brincker, John Augustus Herman, M.B., B.S., M.R.C.S., the Borough Hospital, Croydon,
Buck, Edward Clarke, Assistant City Engineer, Pretoria, Transvaal, South Africa.
Casey, Mark Patrick, Municipal Engineer, Lucknow, India.
Crosse, L. Arthur, J.P., R.M. Office, Nqutu, Zululand, Natal, South Africa.
Densham, Sidney Charles, 152, Adelaide-road, N.W.
Johnson, Charles Grove, F.R.I.B.A., Apartado 610, Mexico City, Mexico.
Lisbôa, Miguel Arrojado Ribeiro, M.Am.I M.E., Rua Costa Gama, Villa Japurá, Petropolis, Rio de Janeiro, Brazil, South America.

Perry, George A., 13, Carlton-road, New Southgate, N.
Redwood, Iltyd I., Bantry-house, Belvedere, Kent.
Sparrow, Reginald George, Lenton-avenue, The Park, Nottingham.
Vidyasagar, Panjabbhudana Pandit Bulakirama Sastri, M.R.A.S., Mayo College, Ajmer, Rajputâna, India.

The paper read was—

THE BRITISH ART SECTION OF THE ST. LOUIS EXHIBITION.

By Isidore Spielmann, F.S.A.

It is my intention this evening to endeavour to undertake the extremely difficult task of presenting to you in a brief space of time a description of the British Art Section of the St. Louis Exhibition which closed in December last. I want also to say a word or two upon the objects and advantages of Art Sections at International Exhibitions; I want to tell you how Art exhibitions are promoted, and I want to say something also about the work they involve, the results they achieve, and the lessons they teach.

I should perhaps preface my remarks by stating that although I helped to organise this section as a member and honorary secretary of the Art Committee, I did not go to St. Louis; but from my acquaintance with the work on this side and the abundance of material and the numerous illustrations I have collected, I am, I think, in a position to bring this section vividly before you.

The section devoted to Art is invariably regarded as one of the chief features of attraction in every International Exhibition. Without it an exhibition would be incomplete, and would be as dull and uninviting to the great majority of people, as would be a landscape without trees or water. "While manufacture is the work of hands only," said Ruskin, "Art is the work of the whole spirit of man." Art adds refinement and adornment to an exhibition, and, by the immense pleasure it affords, has not infrequently been able to turn the scale from failure to success. We should place great faith in the educational possibilities of exhibitions generally, because to many persons the knowledge derived from them is more easily, usefully, and more rapidly acquired than by reading, for the obvious reason that it is usually possible to receive it at exhibitions in a more attractive, striking and inviting form.

Exhibitions would perhaps be better understood and more fully appreciated if the public only knew how much labour, time and trouble are devoted to their organisation, and what difficulties must be overcome in their successful promotion. "How an exhibition is promoted," would in itself provide an excellent subject for a separate paper. From start to finish the subject bristles with difficulties, and difficulties we know are never absent from the formation of an Art Section. These difficulties can only be realised by those who have attempted the task. They commence with the formation of the art committee, and the efforts made to safeguard the many interests in Art representation, for every school or group of painters nowadays wishes to be specially recognised as a factor in the Art of the time.

The difficulties are met with in the attempt to draw up the right lists of artists, and to secure the right exhibits that will do honour to the country, in obtaining the works specially required by the committee from the artists, or in persuading private owners to part with their treasures, and remain content with vacant spaces in their dining-rooms for a time; or in tracing the whereabouts of pictures or sculpture that have passed through a variety of ownerships, sometimes to be met with refusal in the end. And when a good display is eventually secured, other difficulties are often present in the endeavour to obtain adequate space in which to show it, and the right location of that space. But when with plodding perseverance and unlimited patience these difficulties are eventually overcome, and the exhibition is opened, the pride with which one regards the ultimate result—only those who have taken part in such work can appreciate its pleasures.

You will readily understand that the success of an Art Section largely depends upon the willingness of artists and of private owners to place their works at the disposal of the organising committee.

There was a time—not so many years ago—when any work of art was considered good enough to send to an international exhibition with which to represent this country. I am old enough to remember, as a schoolboy, watching groups of foreign visitors to a British Art Section laughing at the works there exhibited with every justification for their merriment; but things have fortunately changed, and in recent years very searching selections are made not only of the artists to be represented, but also of the works they actually send, so that the British school in its various branches may be presented at its best and by the most

representative art only, that can possibly be procured.

As a result, the collection of British works sent to Paris in 1889 was good, that sent to Chicago in 1894 was better, but that sent to the Brussels International Exhibition in 1897, was by far the best collection of modern British Art that had ever been sent out of the country. After Paris and Chicago foreigners ceased to regard England as a barren and stony land in which the arts cannot grow; but the undoubted success of our Art display at Brussels came as a revelation to all those who were not previously acquainted with our Art, for it was in many respects the most admirable feature of the whole exhibition; not only to Belgium did this come as a revelation, but the same idea was echoed throughout Europe. As a consequence foreigners no longer express surprise when they find Englishmen who can paint and model. But the knowledge they acquired is a plant of slow growth, and it will not grow at all unless advantage is taken of each opportunity that presents itself. The British Art display at Paris in 1900 was again very good, and was generally regarded as the best of the Foreign Art Sections.

That at St. Louis—the one under consideration—I had better describe in the words of Mr. Humphry Ward, who wrote of it thus:—"The result is that, although the committee have exercised a somewhat severe method of selection, they can justly point to the British contribution in the Department of Fine Art as among the best, largest, and most important that has ever been sent from our shores. It is equal, or superior, to the display made at Chicago, better than that made at Paris in 1900, and not inferior, in the opinion of good judges, to the remarkable collection sent to Brussels in 1897."

Having succeeded, therefore, in forming a strong Art Section, the least we could expect was that it would be well housed both as regards adequate and well-situated space. At St. Louis it was unfortunately neither adequate nor well situated as compared with the positions allotted to our neighbours. The reason of this is not difficult to explain, and constitutes a disadvantage to which this country has to submit at so many international exhibitions. I have spoken of it for years past, even to Government officials, and I would like to repeat it here.

It may be fairly assumed that Great Britain is invited to participate in foreign international exhibitions at the same time as other countries, but, unlike other countries, we have no permanent and special department by which such enterprises can be organised. In France and in Germany there exist permanent Government Departments which are always ready at short notice to begin the work associated with their participation in international exhibitions. It is not so with Great Britain. Here upon the receipt by the Foreign Office of an invitation to take part in an international exhibition that Department confers with others—with the Treasury, which furnishes the funds that may be necessary, with the Board of Trade, and in the event of a Royal Commission being appointed, with the Home Office also. After considerable delay which these negotiations occasion, influential gentlemen renowned in politics, commerce, literature, science, and art, are invited to join the Commission. The time occupied by these preliminary arrangements results in Great Britain getting to work considerably later than either France or Germany, who usually have a start of us by many months, during which time they have sent representatives to visit the site of the exhibition, and to see the officials of the exhibition administration, and have in all probability secured the best positions as regards spaces in all the Sections. When Great Britain is ready to move we find to our cost that we have to take the spaces in various sections which France and Germany, and perhaps other countries also, have refused to accept—or at least, have left for us to take.

But it is not only in regard to insufficient and badly situated space that we are often at a disadvantage; the time left in which to organise a display that should be creditable to the nation, is often so short that the work has to be rushed to make up for time lost. The industrial sections as well as the Art Section are therefore often handicapped, and the art committee cannot be set to work until its constitution is settled, and the amount of its grant determined by the executive committee.

When you consider that the time required to organise an exhibition is considerably greater than it takes the exhibition to run, and that the winding-up process is an operation equally long, the time between the closing scenes of the one and the opening scenes of the next is often very short, so that a permanent department, if one were established, would not long remain idle. It might even be utilised for other purposes in between.

If it can once for all be decided that it is beneficial to this country to participate, or should I perhaps say that if we decide that our country cannot afford to be the only country to hold aloof from great international exhibitions, then we should hope to see such a department established either at the Board of Trade or at one of the other Government offices, for only then, and not till then, will Great Britain start fair at these exhibitions in competition with other countries.

If at the St. Louis Exhibition Great Britain has done well it is due to sheer hard work and not to method, or rather want of method; and I am glad to find that my friend, Mr. Walter Reid, who contributed an admirable paper to this Society a short time back on the British Industrial Sections, has come to the same conclusion.

At an early meeting of the Executive Committee of the Royal Commission for the St. Louis Exhibition it was decided to place a grant, not exceeding £12,000, at the disposal of the Art Committee, such grant to include an Arts and Craft Section.

The Art Committee was composed of the Presidents of the Royal Academy, the Royal Institute of British Architects, the Royal Society of Painters in Water Colours, the Royal Hibernian Academy, the Royal Society of Painter-Etchers, of the Royal Institute of Painters in Water Colours, the Royal Society of British Artists, the President of the Society of Oil Painters, the Honorary Secretary of the New Englsh Art Club, and the President of the Arts and Crafts Exhibition Society, together with gentlemen representing the interests of sculpture and other branches of Art.

Mr. Reginald Hunt was appointed as representative of the committee at St. Louis for the Fine Arts, and Mr. Alfred Longden for the Applied Art Section. The Committee held twenty-three meetings; many of them protracted sittings of nearly four hours, at which they considered the selection of exhibits, and here I may say that for St. Louis a new departure was tried. Instead of inviting artists to participate, it was decided as a principle to select works from those which were considered the best that had been produced during the last ten years, in oil and water colour painting, sculpture, architecture, etchings and engravings. This system of selecting works in place of artists was strictly observed, it was excellent in theory but very difficult to work in practice; it greatly increased the work, and necessitated our going through the catalogues of every exhibition that had been held during the last ten years, and of visiting all the exhibitions held during the year. It was determined that no art society would be invited to co-operate as a body, but that all works would be invited and accepted as the work of individuals and not as representing any institution, and that all exhibits should come under the head of "Great Britain and Ireland." In the case of artists applying to exhibit, it was decided that such claims to representation should be based upon their past work and reputation. And as at international exhibitions space is almost invariably restricted, it cannot at such times be regarded as suitable that the younger artists can reasonably expect to make their professional *début*. In addition to the specially invited works, many were selected by the full committee from a very large number submitted to them.

The details connected with the formation of an Art Section are numerous. Insurance for a very large sum had to be completed at an early stage before the insurance market was adversely affected, and in this connection I would state that insurance premium is one of the largest items of our expenditure. Thus, an owner is invited to lend a work, and he consents on condition that it is insured against all risks for the sum of £5,000. If you wish to have the work you must comply with the condition. The pictures sent to St. Louis were insured against all risks, namely, fire, water, theft, damage or loss, at rates ranging from 30s. to 50s. per cent. This was considered moderate, except in the case of sculpture, always a difficult class of exhibit to deal with, and which could not be insured at a lower rate than £3 3s. per cent. for bronzes, and £5 5s. per cent. for marble; plaster we did not send. It is gratifying to note that little damage occurred, the chief claims upon the insurance companies being for broken picture glasses and injured frames, and these latter are rectified before the pictures are returned to their owners.

The other business part of the arrangement includes:—Collecting the works from all parts of the country, packing them in zinc-lined cases, and their transport from London right into the Art Palace at St. Louis, the decoration of the rooms, the installation of the section, the preparation of the catalogue, all this requires a vast amount of time and thought.

Having now told you something of the work of the Art Committee, I will describe in outline

—necessarily in a somewhat faint outline—the Art Palace wherein our Art exhibit was installed.

You are no doubt aware that the vast enterprise which has just closed was devised with the intention of eclipsing all the great international Exhibitions that had preceded it. In this ambitious intention its promoters fully succeeded.

The Philadelphia Exhibition covered an area of 236 acres, Chicago 633 acres, the Paris Exhibition of 1900 336 acres, the St. Louis Exhibition of 1904, 1,240 acres, or as large an acreage as all three combined. The approximate area of the buildings alone at the St. Louis Exhibition was close upon 200 acres. The actual cost of the entire Exhibition, exclusive of the large cost for maintenance, is said to have exceeded £5,000,000 sterling.

The space allotted to the display of Art by the United States and the twenty-three foreign countries participating was on a much larger scale than at any previous exhibition, the actual area of the galleries equalling nine acres, and the cost of the four Art Palaces was about a quarter of a million sterling.

Art Palace.

Three of these buildings faced the Exhibition grounds, and had a frontage of 836 feet. Mr. Cass Gilbert, of New York, was the architect. The central building is of a permanent character and was devoted exclusively to the work of American artists. The wings or side pavilions each covered an area of 420 feet by 200 feet, and were allotted to foreign countries—the Latin races chiefly occupying the right Pavilion and the Teutonic races the left. A fourth building at the back contained large sculpture exhibits from foreign countries. This group of buildings is designed in graceful well proportioned Ionic style, accentuated at the main entrance of the central building by a Corinthian portico of majestic proportions. The architect, of course, avoided the use of window openings in order to impart to the building the accepted characteristic of an Art Palace.

The British Art Section was situated in the left Pavilion. The disadvantageous position of our rooms will be the more apparent when I explain that on the east side, a terrace separates the Pavilion from a park, and as the ground slopes rapidly from north to south, this terrace rises to a considerable height, making it and the south main entrance inaccessible from that direction. A main road with a good entrance would naturally have brought many visitors from that side, especially as the railway passes this point.

Owing to the repeated representations of our Chairman, ably supported by Colonel Watson, our Commissioner-General at St. Louis, this serious drawback was at a later date somewhat remedied by the exhibition authorities constructing a flight of steps from the lower level to our terrace as had been originally promised. On the west, our section could be entered by one doorway leading from the gardens into galleries J and K.

To reach our galleries from the grand entrance at the north side it was necessary to pass through those allotted to Germany and Holland, and it is obvious that the great majority of visitors came to our rooms after having already seen many other pictures, and possibly with appetites too jaded to be ready for further artistic enjoyment.

A glance at the plan on the screen will show that to Germany was accorded not only the best position in this wing, as France was accorded in the corresponding wing, but also a larger amount of space than was allotted to Great Britain.

On the day of the official opening of the Exhibition our Art Section was complete in almost every detail, whilst those of our neighbours, including America herself, were unfinished and consequently closed to the public. As the south entrance was not accessible, only a small percentage of the public found its way to our galleries through the unfinished German and Dutch Sections, whilst those of France in the other wing, which showed a portion of her exhibits, were thronged.

Our galleries, with the exception of K and J, devoted to architectural drawings, were lighted from the top, but it was necessary to diffuse the light by means of a velarium of unbleached muslin, and before the summer months every room was properly shaded.

Decoration.

The walls of our galleries devoted to pictures and drawings were hung with a silky-red burlap; those devoted to the Applied Art exhibits with a biscuit-coloured burlap; the dados and doorways were painted white, and this crimson and white decoration gave a gay effect to our section and distinguished it not unpleasantly from those of other nations, in all of which the colouring was subdued and neutral. Our floor covering, a linoleum of a neutral green shade, harmonised effectively with the surrounding decoration. The effect

of our frieze was decidedly good. It was designed, and for the most part, painted by Mr. Walter Crane, President of the Arts and Crafts Exhibition Society, and a member of the Art Committee. The scheme consisted of a series of shields connected by scrolls of foliage. Inscriptions on the scrolls refer to the contents of the various galleries, those in the Applied Art Section refer to the aims of the arts and crafts movement—the unity of design and handicraft in adaptation, material, and use. In the frieze-panels appear the shields of H.R.H. the Prince of Wales, President of the Royal Commission, the Royal Shield, and about a dozen other shields connected with a design of decorative foliage. You will be able to see the many variations of the frieze presently in the illustrations on the screen.

Mr. E. J. Gregory, R.A., P.R.I., and Mr. Alfred Parsons, A.R.A., were kind enough to proceed to St. Louis to hang the pictures and place the sculpture. They reported that the number of doorways seemed excessive, and they obtained considerable wall space by closing some of them. As I have said, the space given to Great Britain and Ireland was smaller, in proportion to the size of our exhibit, than that provided for most of the other countries, and our pictures had to be hung more closely than would have otherwise been the case. But in the matter of oil paintings and water-colour drawings it was found possible to leave a narrow space between each. A great effort was made to secure Gallery No. 69, but without success, although we understood that it had originally been promised to us.

Messrs. Gregory and Parsons considered that Gallery 81 assigned to water-colour drawings was not large enough for the very representative collection sent over, and they therefore had to utilise three walls in Room 80, reserving the fourth wall for pastels and for small oil paintings. With few exceptions they were able to show to equal advantage the pictures of all schools of British art, and of every class at least one work of each artist represented was placed on the line. In hardly any case was it found necessary to hang more than two lines of pictures, and every picture accepted by the committee was placed in a position where it could be well seen.

Results and Comparisons.

I have prepared a Table showing the number of works sent by Great Britain to the last five international exhibitions. You will note that we contributed to St. Louis nearly 300 oil paintings, about 150 water-colour drawings, 90 pieces of sculpture, nearly 300 engravings, etchings, and drawings, and nearly 200 architectural drawings; in all 1,025 works representing 550 artists and architects. (Table I.)

TABLE I.—Showing number of British Works of Art at the last Five International Exhibitions.

	Oils.	Water Colours.	Pieces Sculpture.	Black and White Drawings.	Architectural Drawings.	Total.	Artists Represented.	Exhibits per Exhibitor.
Paris, 1889......	172	124	40	123	93	552	300	1·84
Chicago, 1894 ..	461	204	53	266	146	1,130	515	2·19
Brussels, 1897 ..	205	109	24	222	54	614	259	2·33
Paris, 1900......	166	89	54	114	47	470	282	1·67
St. Louis, 1904 ..	293	158	90	294	190	1,025	554	1·85

I have prepared a second Table showing how we compared with foreign countries in the number of works we sent, and it will no doubt strike you that both our section and that of France were very large in comparison with that of the United States. (Table II.)

In the Applied Art Section we also exhibited very largely in comparison with other countries. I will return to this section presently.

To complete our comparisons I have prepared a statement of expenditure of the British Art Sections at the last five international exhibitions. We had at St. Louis, 554 exhibitors in the Fine Art Section, and 152 exhibitors in the Applied Art Section, making a total of 706 exhibitors. The Royal Commission made a grant of £12,000 for the entire Art Section, which is equivalent to £17 a head as against £19 at Paris, and £22 at Chicago. (Table III.)

As I have said, the entire British Art Section was completed in time for the official opening

on April 31, 1904, and was the only one which had its catalogue on sale to the public. For a considerable time after the opening ours was the only catalogue obtainable in the Art Palace. Not even was the American catalogue ready. It appeared only in June or July I think. This was the case also in all the other sections of the Exhibition, where the British Industrial Catalogues were, I believe, the only ones to be had for many weeks. We may pride ourselves on the fact that this was the case also at Brussels, 1897, and at Paris in 1900.

In studying the collections as well as the decoration of the galleries of the various nations, a distinct and characteristic expression of individuality of style is readily noticeable. I would like to show you one or two illustrations of the galleries of other countries so that you may, by comparison, be able to fo m a better judgment of our own.

The illustration on the screen is of one of the rooms in the American Section. It is from a block print, and is not very good.

The central portrait on the north wall is that of the Empress of China, by Miss Carl, a citizen of the United States, and the following reference to it from our representative at St. Louis is rather amusing:—"It is," he says, "The only portrait that has been painted of the Empress, and represents her seated on a throne in Eastern costume. Miss Carl was not allowed to paint the portrait in the way she wished, and had to follow the instructions of the Empress. When the picture was finished and removed from the precincts of the sacred city, it was considered to be in some sense a part of the Empress herself, and it was thought necessary to clean up the streets and decorate the passages from the palace to the river where it was shipped. The cost of repaving the streets and generally decorating the route is said to have exceeded £2,000. The portrait

arrived at St. Louis in charge of an escort of eleven Chinese, headed by Prince Lung. It was in a huge case, and occupied a tremendous time to unpack, and the men were only allowed to handle it with their hands covered with silk. The picture itself was wrapped round and round in silk, and was contained in a specially sealed case. The portrait had to be held constantly in an upright position out of respect to the Empress. It is a gift from the Empress to the American Government.

The walls of the United States Galleries were decorated with red or pale green jute, while the friezes by Charles S. Holloway, representing seated female figures with garlands of flowers containing the names of the prominent American artists, harmonised with the decoration of the walls.

The French Section contained the largest collection of pictures and sculpture that has ever been sent from that country, and was fairly representative, although it appeared that many of the most distinguished artists were not represented by their best works.

The scheme of colouring dominating their section was a neutral red, and the frieze was from a design by Besnard. It consisted of a conventional figure closely repeated; the colours employed being a deep golden brown, blues, and red.

The large space allotted to Germany was chiefly occupied with enormous historical canvases from the public galleries that had been painted by Imperial order. They are said to have been interesting historically, but from the artistic standpoint of less importance than many works that might have been included with greater advantage.

The chief gallery assigned to German art exhibits, as in Paris, was decorated with a somewhat monumental treatment of the walls, but the general effect is said to have been dignified and serious.

Holland sent a good collection of works by her best artists, and the decoration of her section was made up of broken greens and greys, with a frieze in which dull purple and dark green harmonised well with the walls.

The scheme of colouring in the rooms of the Belgian Section was of russet and gold, and in their frieze the names of the great masters of the Flemish school were introduced. Belgium's art exhibit, I understand, was stronger in sculpture than in painting.

The Italian Section was again disappointing. It is unfortunate that Italy has failed to make a favourable impression in modern art at recent international exhibitions. The decoration of their walls and their frieze, however, were good and original, and were embroidered in harmonious colours.

Japan had a large exhibit of noted examples of their old school of art, as well as paintings by younger artists in the European style. She also sent a large collection of sculpture in ivory, wood, and bronze, which greatly enhanced the success of her section. The decoration of the Japanese rooms consisted of a general scheme of colours of positive tints, green and blue predominating, and the frieze was by Japanese artists, who worked it direct on to the walls.

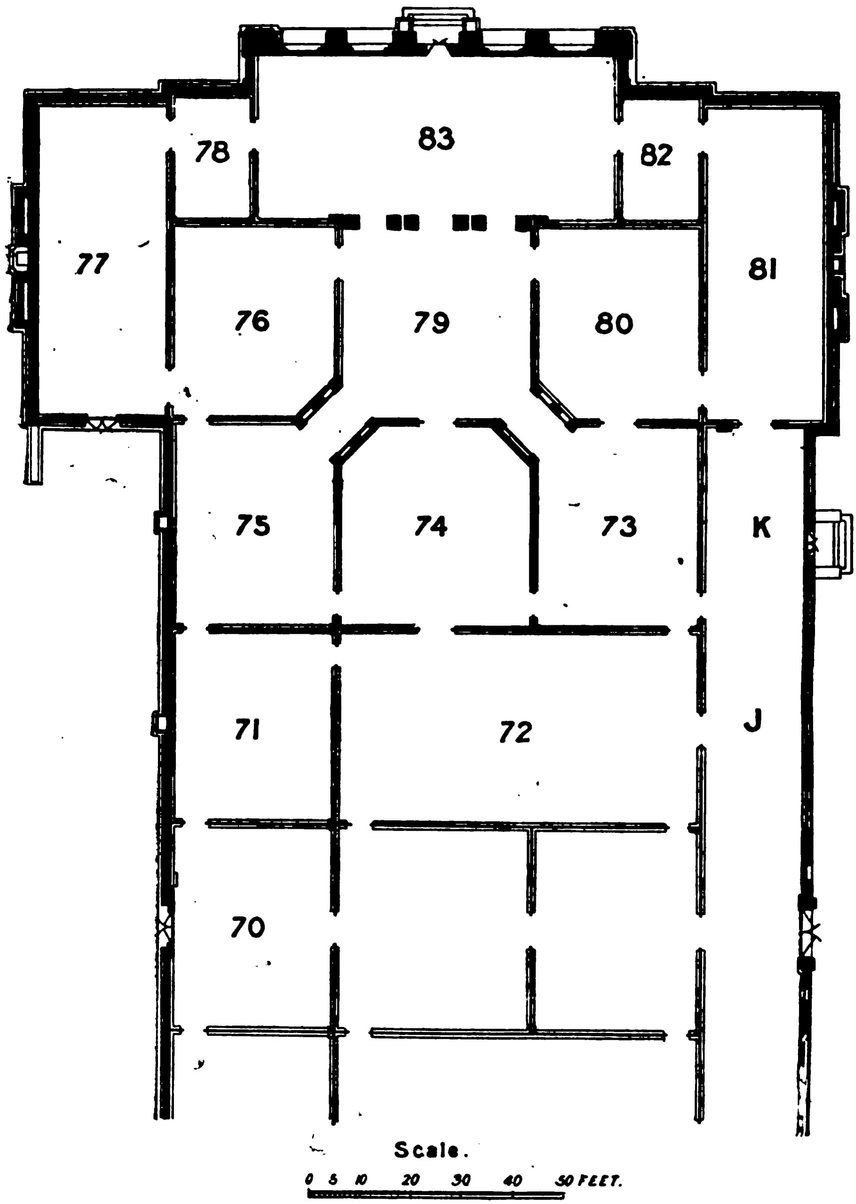
And now I will ask you to accompany me through our galleries, following them in their order on the plan. To save time, I propose showing but one general view of each gallery, and then a few special works contained in each. It is manifestly impossible to show you all of them.

To make a selection at all is extremely invidious, and it has therefore occurred to me that it would be interesting to place before you some amongst those works which appear by general consensus of opinion to have most impressed local critics and visitors. This seems to afford the only basis on which I can make a selection—quite apart from the question of the excellence of photographs available. Besides, it is always interesting to know the impression that is made upon others than ourselves. And I must invite you to accompany me round the galleries as your "guide" who has learnt his way, and not as a critic.

The first room approached from the German Section is No. 70, which was devoted exclusively to black and white work; drawings in pen, pencil and chalk, etchings and engravings, too many I fear to show to advantage in the limited space; but we were anxious to have the collection as complete as possible, and few, if any, of our most important men were absent. Not only were our etchings both good and representative, but we had no reason to be ashamed of the examples of our characteristically English art of mezzotint displayed. Here we were able to show upwards of twenty very fine drawings by Burne-Jones, a dozen by Leighton, and several by Sir Seymour Haden; and ninety other eminent artists exhibited in this section.

Room 71 is the first of those devoted to oil paintings. Here in the centre is Orchardson's

portrait of "Sir David Stewart, late Provost of Aberdeen." Without in any way criticising the work I ought to tell you that this superb picture produced an immense impression at St. On the left—(1) "Wet Sands," by William McTaggart, R.S.A.; (2) "Portrait of Admiral Fisher," by A. S. Cope, A.R.A.; and (3) Ernest Parton's, "In the Tangled Wild Wood."



Plan of British Art Galleries.

Louis. On the right are—(1) "The Pilot," by Napier Hemy, A.R.A.; (2) "The Portrait of Professor Kennedy," by Hugh Riviere," and (3) "Evening's Twilight," by J. E. Grace, R.B.A. Above is John Lorimer's "Idyll Autumn." Above is Fred. Appleyard's "Easter Time." The room contained many other well-known pictures: "Brown Autumn," by Alfred Parsons, A.R.A. The picture was painted on the upper Thames above the point where

its junction with the Severn Canal makes the river navigable for barges. "God rest ye merry gentlemen," by Seymour Lucas, R.A., one of those delightful Christmas carols of the 17th century; "Portrait of Mrs. Reynolds and Daughter," by Luke Fildes, R.A.; "The Flowing Tide," by Moffat Lindner, N.E.A.C.; "The Storm," by Julius Olsson; "The Fracture," by William Orpen, N.E A.C. A point of great interest in this picture is that the room represented is that in which Thackeray lived in Soho and wrote "The Newcomes." The artist's intention is an exercise in the rendering of light. "La Belle Dame sans Merci," by Frank Dicksee, R.A. The idea is taken from Keats' ballad, and depicts the passage—

"I set her on my pacing steed,
And nothing else saw all day long,
For sidelong would she bend and sing
A faery's song."

La Belle Dame, in a gown of rose-colour and silver, her red floating hair shadows the knight as she bends over him. He is held by the magic of her thrall, an ecstasy of wonder and devotion possesses him. Under this spell he is taken to her grotto to be lulled asleep, to dream dreams and to meet the fate awaiting him.

Room 72 contained a large number of important works, many by Scottish artists. In the centre was Sir John Millais' "Chill October," one of his best-known and finest works, lent by Lord Armstrong, which you will see again presently; above it, "On the Threshold," by Ernest Normand. On the right — (1) Millais' "Portrait of Cardinal Newman;" (2) the President's picture, "The Catapult;" (3) "The Lilypond," by G. D. Leslie, R.A.; (4) "Scene from Enoch Arden," by J. Sant, R.A. On the left — (1) Sir John Millais' "Portrait of Sir James Paget;" (2) the President's "Greek Dance;" (3) A sea-piece by J, C. Hook, R.A. In this room were also Lord Leighton's "Perseus and Pegasus with the head of Medusa;" "Portrait of Cardinal Manning," by W. Ouless, R.A.; "The Dream of Launcelot," by Burne-Jones; "Portrait of Lord Charles Beresford," by Charles Furse, A.R.A.; and pictures by Peter Graham, R.A.; W. F. Yeames, R.A.; Briton Riviere, R.A.; the late Val Prinsep, R.A.; Ogilvie Reid, R.S.A.; Byam Shaw, and T. B. Kennington; and the "Portrait of Sir Walter Gilbey," and "The Borgia," by W. Q. Orchardson, R.A.

"Chill October," by the late Sir J. E. Millais, R.A. Pasted on the stretcher at the back of this picture is a sheet of paper, on which the painter has written the following note:—

"'Chill October' was painted from a backwater of the Tay just below Kinfauns, near Perth. The scene, simple as it is, had impressed me years before I painted it. The traveller between Perth and Dundee passes the spot where I stood. Danger on either side—the tide which once carried away my platform, and the trains which threatened to blow my work into the river. I chose the subject for the sentiment it always conveyed to my mind, and I am happy to think that the transcript touched the public in a like manner, although many of my friends at the time were at a loss to understand what I saw to paint in such a a scene. I made no sketch for it, but painted every touch from nature, on the canvas itself, under irritating trials of wind and rain."

"Fantasie en Folie," by Robert Brough, A.R.S.A., the able young artist whose life was so sadly cut off by the terrible accident which recently occurred on the Midland Railway. This picture attracted great attention when it was exhibited at the Royal Academy, and still more at St. Louis. It represents a lady in black, seated in profile, contemplating a Chinese idol.

"The Portrait of J. C. Hook, R.A.," by Sir John Millais, is generally considered, with the possible exception of his "Sir Gilbert Greenall," the finest and most brilliant portrait he ever painted of a man.

One can hardly look at a fine portrait like this without recalling Ruskin's famous saying that, "The highest thing that art can do is to set before you the true image of the presence of a noble human being. It has never done more than this and it might not do less."

"The Avenue," by D. Y. Cameron. This picture was greatly appreciated at St. Louis, quite as much as at the Brussels Exhibition, and was considered a good typical example of the Scottish school. The prevailing notes of colour are rich olive, brown, gold and rose.

"The Auld House," by J. Macaulay Stevenson, is a picture which in feeling, of course, reminds one of Corot. The house is really a very inconsiderable item. The lake and its reflections of trees with undergrowth and atmosphere charged with moisture, are characteristic of the painter's work.

"Portrait of W. W. Robertson, Esq., Master of the Merchant Company of Edinburgh," is considered an excellent specimen of the work

of Sir George Reid, late President of the Royal Scottish Academy. Sir George also sent a "Portrait of Tom Morris," the celebrated golfer.

"The Borgia," by W. Q. Orchardson, R.A. Cæsar Borgia is best remembered for the remorselessness with which he rid himself of those who stood in his way. He generally did so by inviting his intended victim to a banquet, at which he would challenge him to drink wine, served to the doomed man in a poisoned cup, the other guests stealing away, for "to drink with the Borgia" was an honour which became synonymous with death.

Mr. Orchardson's other works at St. Louis were his portraits of Sir Walter Gilbey and Sir David Stewart.

In Room 72, "The Image Finder," Bronze statue by W. R. Colton, A.R.A. A work of much originality and strength, and interesting in motive.

"A Wounded Leopard"—in bronze, by J. M. Swan, A.R.A. This bronze is a fine specimen of casting by the *cire perdué* process. It represents an East-African Leopard pierced through the shoulder and fore-arm by an arrow; the head of the arrow is bitten off and fallen, and the animal is biting and tearing at the remainder It is a life-size work about three feet square at base and three feet high, and was begun and executed for Mr. George Jay Gould of New York, by whom it was lent. The finished bronze has never been exhibited here, only an early sketch of the work in plaster.

Room 73 contained:—Mouat Loudon's "Alas, that Spring should vanish with the rose;" David Murray's "Braes of Yarrow;" J. Young Hunter's "Forest Lovers;" Sir Wyke Bayliss' "The Sanctuary in the Certosa, Pavia;" Leighton's "Clytemnestra;" W. Hatherell's "River Picnic;" Perugini's "The World Forgetting."

On the opposite walls were, amongst others, Solomon J. Solomon's "Portrait of Mr. J H. Levy;" Marcus Stone's "Soldier's Return;" John Collier's "Prodigal Daughter;" Arthur Hacker's "Leaf Drift;" and H. von Herkomer's well-known and widely exhibited picture, "Makers of My House," which represents his father and his two uncles.

"The Doll's House," by William Rothenstein, N.E.A.C When I asked the artist to describe this picture he replied that he had wanted to paint a man and a woman suggesting something of a mystery which underlies all life, and something of the dramatic possibilities of every situation. The title was only thought of when the picture was first exhibited in Paris. It was suggested partly by the room and partly because there seemed to be something akin to the lack of finality in Ibsen's semi-tragic plays. The only pieces of sculpture in this room were:—"Robert Burns," a statuette, by W. Hampton, and "Cock and Snake," bronze group, by J. H. Furse.

In Room 74 was Leighton's "Perseus and Andromeda;" Henry Moore, R.A., the greatest marine painter of his day, "Storm Brewing" and "St. Alban's Race;" Arthur Nowell's "Portraits of his Sons;" "The Sawing Horse," and "Tucking the Rick," by H. H. La Thangue, A.R.A.; J. E. Christie's "Pied Piper of Hamlin;" "The Duck Pond," by Fred Hall.

In the same room were—"Washing the Beggars' Feet," by Sir James Linton, R.I., and works by Edward Stott and George Haité, and three by Sir Lawrence Alma-Tadema, R.A.

The well-known "Shrine of Venus" is one of the three Sir Lawrence sent to St. Louis. It represents a hairdresser's shop, classically imagined. The shop is in the middle plan, through which the clients have to pass. On entering the inner room they deposit a small offering, lay the usual marigold or a rose on the table before the Shrine, in which is a statue of Venus.

This picture now finds a home in America, where so many works by this artist now are. It changed hands during the Exhibition, and I am able to let you see it once more, by the courtesy of the Berlin Photographic Company.

"The Rainbow," by P. Wilson Steer, N.E.A.C., was painted at Bridgnorth, near the town through which the River Severn flows. It was the object of the artist, like so often that of Constable, to give the sparkle on foliage while a shower is falling, the effect being late afternoon towards autumn.

"Cave of the Storm Nymphs," by Sir E. J. Poynter, P.R.A. The picture is intended to suggest the indifference of nature to destruction, and the worthlessness of the prizes of life in the face of the elements. In the presence of the artist it could hardly be becoming in me to dilate upon its beauties.

"The Quartette," by the late Albert Moore, one of the most charming of that artist's works. It is quite remarkable for the grace of its artistic drapery and its exquisite colouring.

"Hylas and the Nymphs," by J. W. Waterhouse, R.A. The story you will recollect is that Hylas, a Greek youth who was sent to fetch water from a certain pond situated amongst some hills, was carried down by the water nymphs. This is one of Mr. Waterhouse's best pictures, and was kindly lent by the Corporation of Manchester.

"The Rick Yard," by George Clausen, A.R.A., was also in this room, but this picture, like so many others, would not photograph well.

In Room 75 the centres were occupied by—(1) "The End of a Glorious Reign: The Funeral of Queen Victoria," by John Charlton; (2) "The Homage-giving, Westminster Abbey: Coronation of Edward VII.," by J. H. Bacon, A.R.A.; (3) "Washington's Farewell to the Army," by A. C. Gow, R.A. We also had in this room:—"The Dream Princess," by Mrs. Stanhope Forbes, A.R.W.S.; "Bolton Abbey," by David Murray, R.A.; "Alpine Scenery," by J. MacWhirter, R.A.; "A Sea Maiden," by Herbert Draper; and "Warkworth Castle," by Sir Ernest Waterlow, R.A., is the ancient stronghold of the Percys in Northumberland. It is picturesquely situated two miles from the sea, and is painted in Sir Ernest's happiest and most dignified manner.

Room 76.—Here we had: "Shrimpers," by R. McGregor, R.S.A.; "A Higland Solitude," by A. K. Brown, A.R.S.A. "Portrait of Tom Morris, the Golf Player," by Sir George Reid, R.S.A.; "Drowsie Cronies," by R. Alexander, R.S.A.; "In the Highlands," by Peter Graham, R.A.; "Serena Found of Savages," by T. B. Kennington; "Across the Snow they Travel," by Joseph Farquharson, A.R.A. On the other wall, "British Wild Cattle," by H. W. B. Davis, R.A., and a "Portrait of Mrs. Denny," by W. W. Ouless, R.A. I regret that a few of these and many others besides did not photograph sufficiently well to allow of slides being made of them.

"Boulter's Lock," by E. J. Gregory, R.A. This picture represents the most characteristically crowded part of the Londoner's playground. The time is about five o'clock on a Sunday afternoon, rather late in the season, when the deep lock with its struggling occupants is full to the brim of shadow, but still girt by a sunlit landscape, into which they strive to emerge. The artist is himself afloat, in two different boats. When this picture was shown at the Brussels Exhibition, there was, in the French Section, another rendering of the same subject; it was curious how Mr. Gregory's version seemed to wipe the Frenchman's out of artistic existence.

Room 76.—"King Edward I.," bronze equestrian statue, by Hamo Thornycroft, R.A. It represents the great Monarch and law-giver mounted on horseback, with a Plantagenet shield slung at his back, and holding in his right hand the famous Statute of Winchester. This was originally designed for the great competition for the decoration of Blackfriars-bridge, 20 years ago. Having got this fine model from Mr. Thornycroft, the Sewers' Committee of the City of London took fright, and decided not to venture any further action—beyond the consideration of its sewers. At least, nothing has since been done.

"Castles in the Air," a statuette and pedestal in metals, marble and inlays, by W. Reynold-Stephens. This is an attempt to embody a child's profound realisation of a wonder story. A little girl of about two years leans back in a chair of enchantment, which stands upon a pedestal, the design of which is based upon fairy-castle forms. Flowers of fancy decorate the chair which is capped by a wonder-castle in mother of pearl.

Here in Room 77 we had "Surrey's Pleasant Hills," by B. W. Leader, R.A.; "The Return from the Ride," by the late Charles Furse, A.R.A., N.E.A.C. The portraits are of Mr. and Mrs. Aubrey Waterfield—then Miss Lena Duff Gordon. This was one of the most noted pictures in the Royal Academy in 1903, and was praised by all the critics as being finely designed, ably drawn, good and original in colour, and altogether a strong and remarkable achievement. Unhappily, as you know, Charles Furse died last year.

"Shrimpers off the Coast of Brittany," by R. McGregor, R.S.A. The exquisite golden tone of the sun-burnt faces and hands against the silvery grey of the sea and sky were the artist's chief motive in painting this picture. On the opposite wall were:—"Portrait of Lady Hickman," by A. S. Cope, A.R.A.; John R. Reid's "Rival Grandfathers," an old picture; the late M. Ridley Corbet's "Sunrise."

"The Cider Press," by Frank Brangwyn, A.R.A., in which we have one of those compositions, founded apparently on a simple natural scene, which yet contains so much more than we ever realise at one time. Though the "Cider Press" gives the title to the picture, we feel that the artist's mind has been occupied with the enduring conditions of natural

human labour, perhaps even more with the perennial beauty of sunlight, and, above all, of noble design.

"Venus and Anchises," by Sir William Richmond, R.A., deals with a theme as old as human nature,—the association of love with the renewed life in springtime. This is one of Sir William's most successful pictures, and was lent by the Walker Art Gallery at Liverpool.

"The Edge of the Somme," by Alfred East, A.R.A., is a decorative picture. Its colour scheme consists of a series of yellow greys and ivory white. The sentiment it expresses is the quiet of an early morning. It was painted in London from sketches and studies made in the beautiful valley of Amiens. In the immediate foreground, the cool white colour of the swans forms a pleasing note in relation to the warm white of the sky.

Room 80.—This room was devoted to small oil paintings and to water-colour drawings, but they are on too small a scale for you to see much of them. Here were:—

"The Wavelet," bronze statue by W. R. Colton, A.R.A., representing a girl playing with the water that trickles over the rock. It attracted great admiration among the visitors.

"The Habit does not Make the Monk," a small oil painting by the late G. F. Watts, R.A., is one of that playful character which Mr. Watts affected more and more as age came upon him.

The "May Morning on Magdalen Tower, Oxford," by W. Holman Hunt, is the finished study for the large picture. On the First of May at sunrise, for many generations, the choristers of St. Mary Magdalen College, Oxford, ascend with a band of music to the top of the tower belonging to their seminary and sing the Hymnus Eucharisticus.

"St. Theophilus and the Angel" is an important water colour by the late Sir E. Burne-Jones. After the death of Dorothea, as St. Theophilus was returning to the Courts of Law, there met him on the threshold an angel bearing a basket of fruit and flowers, who, saying, "My sister Dorothea sends these to thee from the place where she now is," vanished. Theophilus, pondering all this, came at last to the true belief, and in it died.

"The Prioress' Tale," also by Sir E. Burne-Jones. This, as you will remember, was the last work completed by the artist.

We now come to the water colours. To them Room 81 was devoted exclusively. This collection came under close observation and criticism, in view of our claim that water-colour painting is our national art. I now show you a few examples that were here exhibited.

"The Battle of the Standard," by the late Sir John Gilbert. P.R.W.S., so-called after the remarkable standard which was set up by the English at Northallerton during the war between King Stephen and King David I. of Scotland in 1138, an exceedingly powerful drawing.

"Cumberland Moors," by the late Tom Collier, R.I., is an excellent example of his admirable work. Tom Collier was essentially a water-colour painter of the first rank, and by his untimely death in 1891 English landscape art lost an artist whose work rivalled that of David Cox in quality.

"The Battle of Flowers," by R. Anning Bell, R.W.S., shows a silvery grey hall, in which a vigorous battle is going on between two parties of girls in loose flowing garments. Everything is in movement, for movement is the *motif* of the drawing; the wide loose dresses swirling out from the girls, or here and there pressed close to their form, as the action varies.

In "Andromeda," by Arthur Rackham, A.R.W.S., the subject chosen is the moment when the great sea-monster is approaching to devour his victim. He is grey-scaled and slimy like a fish, with webbed feet, and comes from the gloom of a cavern, crawling over the rock at the foot of which is Andromeda chained. The colour is rather grey and subdued; the drawing of the monster, wonderful. Mr. Rackham is a specialist in dragons!

"Melisande," by Mrs. Adrian Stokes. Melisande is seated on a rock in a weird forest, gazing dreamily in the water where her crown lies. The story does not tell what crown it is, or where Melisande came from; but she hates the crown and does not wish ever to touch it again. There is no other note in the picture than red, black, or white. "The Thorny Path of Knowledge," by J. Walter West, R.W.S.—a dainty little picture of a young Quaker mother teaching her child to read—is a typical work by one of the most brilliant of the younger Associates of the R.W.S. "A Valkyrie," by Edward R. Hughes, R.W.S. This Valkyrie leaves her Valhalla, and is soaring above a city formerly the scene of strife and heroism, but now at rest from warfare and asleep in the moonlight. The artist intends her to seem peering into the depths from the back of her winged war-horse, as though she had a great longing to live with

mortals in their beautiful city, through whose heart flows for ever a life-giving river. Sir Francis Powell, P.R S.W., John Fulleylove, R.I., the late Charles Green, R.I., Dudley Hardy, R.I., and Yeend King, V.P.R.I., as well as the Presidents of the Water-colour Societies, were all represented in this room.

The sculpture exhibited here included:—"Hymn to Demeter," in bronze, by Horace Montford, representing a girl marching in procession as she sings her hymn. She fits her steps to the music, the measure ever varying, her body bending and swaying to the same rhythm.

"Love and the Mermaid," a bronze group by Charles J. Allen, is supposed to represent Cupid, love-god of the earth and air, who has wandered on to an outlying ledge of rock, and encountered a rival power in the witchery and charms of a Mermaid instinct with love and the sea. He stands bewildered and fascinated, and likely to fall a half-willing prey to the wiles of the fair captor.

"Boy with Top," a bronze by E. Roscoe Mullins, is a fine rendering of nature.

Gallery J and K was devoted to Architecture. Here 200 works represented 70 of our leading architects. It is impossible to read so long a list of names, but I think I can safely say that very few eminent men in that profession were unrepresented. British architecture, as is universally admitted, has made great headway of late, and the carefully selected works sent to America for this section must have convinced the public that we have able architects as well as painters and sculptors.

The works on the left screen should, strictly speaking, have been exhibited with sculpture. They are magnificent photographs of the model of Mr. Brock's Memorial to the late Queen Victoria. The top one is a single photograph and is seven feet long by five feet in height; this will give an idea of the length of the gallery.

Room 79 connected the Fine Art with the Arts and Crafts Section, which you see through the columns. The pictures here:—"The Brook," by Leslie Thomson, R.I.; "Saving the Colours by the Guards at Inkermann," by Robert Gibb, R.S.A.

Room 79A.—The main collection of sculpture, although small, was representative, only one or two eminent sculptors being absent. Many of the busts and groups were placed round the walls of Gallery 79, where they showed to great advantage and added largely to the general effect. Some of the smaller bronzes, as you have seen, were grouped upon pedestals in Gallery 72 and round the Water-colour Gallery 81.

The short passage leading from Gallery 79 to Galleries 73 and 75 was well lighted from the side, and afforded good positions for a few bas-reliefs.

The following were among the chief sculpture exhibits:—

"Eve," a bronze statuette by Thomas Brock, R.A., represents the Universal Mother standing with her head bent forward, her left hand on her breast, and her long hair falling down her back and over her shoulders, the serpent coils round the base, which is circular in general form on a square plinth.

"The Sluggard," a masterpiece, if not the masterpiece, in sculpture by the late Lord Leighton is too well known and appreciated to need praise. The sluggard presses a laurel wreath under the heel of his right foot, a touch of morality, unlike Leighton's usual practice, being introduced.

"Teucer," in bronze, by Hamo Thornycroft, R.A., was, you will remember, the Homeric bowman famous at the Siege of Troy.

"The Kiss," by A. G. Walker, is a work which was carved direct in the marble, no preliminary clay model having been made, but merely a shaded drawing on the marble slab.

"Snowdrift," by the late E. Onslow Ford, R.A., is a recumbent female nude figure in white marble on a plinth of Mexican onyx. This charming work is one of the artist's last works, and was exhibited in the Royal Academy in 1902. It is about four feet long.

"Mother and Child," the beautiful bronze bust by George Frampton, R.A., includes the portraits of Mrs. Frampton and the artist's son; the group is life-size.

"The Spirit of Contemplation," a life-size bronze figure of a girl reclining in a neo-classic seat decorated with small figures of Courage, Philosophy, Life, Love, and teh like. The work is by Albert Toft.

"Psyche," bronze ideal head, by F. Lynn Jenkins. In it the sculptor, who is perhaps best known as a decorative worker, has aimed not merely at reproducing beautiful form from Nature but also at expressing the less tangible beauty of the soul underlying.

"Age of Innocence," bronze bust by Alfred Drury, A.R.A. An ideal bust of a child in which the sculptor endeavoured to portray the

innocence, simplicity, and *naiveté*, and above all, the young flesh of childhood.

"The Breton Peasant," by Professor Lantéri. The original of this bust in bronze is at the Musée de Luxembourg, and also at the Tate Gallery (each claims to have it!) It was modelled as a practical demonstration before some French sculpture students in the north of France.

"The Last Song," by H. Pegram, A.R.A. The idea is that of an old soldier dying, to whom a maiden comes and sings of his past deeds and future reward.

Room 83, with the two small rooms, 78 and 82, contained our Arts and Crafts exhibits, or, as the Americans termed them, original objects of art workmanship.

For the first time in the history of international exhibitions, these were shown on a large scale side by side with the fine arts. A similar course was attempted at Chicago, but the response was then but meagre. Our American friends decided that at St. Louis the line which has hitherto separated applied art from the fine arts should be obliterated, and that, under the broader classification, any work, whether on canvas, or in marble, plaster, wood, metal, glass, or in textiles, is equally deserving of recognition from the standpoint of conception and technique. The unity of art, therefore, which lay at the root of William Morris' teaching, was fully recognised at St. Louis.

As you are probably aware, these artists, or groups of artists, work co-operatively, and both design and execute the works they produce. The United States exhibited nearly 1,000 original objects of art workmanship. Great Britain came next with over 400—the largest collection of its kind we have ever contributed to any exhibition. France followed with nearly 200 objects, and the other countries were far behind.

In the selection of their exhibits, the Arts and Crafts Sub-committee, presided over by Mr. Walter Crane, R.W.S., had a completely free hand, and Mr. Halsey Ricardo went to St. Louis to arrange them.

Room 83A.—Testimony should here be borne to the very great beauty of the bookbindings that were sent, besides the artistic pottery, dainty and elegant glass, refined jewellery, brilliant enamels and illuminations, which completed this intereting collection, and I am only sorry that time does not permit of my selecting individual objects for your closer inspection.

These were some of the chief features of this display of British Art which has now been dispersed: but I must repeat that amongst the remainder which you have not seen were numerous works of equal interest. Some of them I hope to include in the Illustrated Souvenir which I am preparing for the Royal Commission. They may also be seen by reference to our catalogue, of which a few hundred copies remain, and can be obtained on application to the offices of the Royal Commission for the St. Louis Exhibition, 47, Victoria-street. It is a useful book, and contains, besides the catalogue of the Fine Arts and Applied Arts Section, a condensed "Who's Who" of over 550 eminent British artists and architects.

It is a matter of some interest that our section was the first to be dismantled and packed up, and that we were the first to get away. In this we were not assisted by the United States Customs and other Administrations, and we found that it is even more difficult to get things out of the country than into it. They evidently parted with us with great reluctance.

The United States duty upon paintings in oil and water-colour is 20 per cent. *ad valorem*, upon black and white drawings it is 25 per cent. *ad valorem*, whilst the duty upon pictures imported into the United States from France, Germany, Italy, &c., is but 15 per cent. It is difficult to suggest a reason for this preferential tariff in favour of non-British countries, but the cause is probably to be sought in the fact that they are able to offer some corresponding advantage to the United States. The artists of Great Britain are selected as the victims—though not the only victims of the open door which Great Britain throws wide to all comers—and they are consequently compelled to pay considerably higher duty than their foreign rivals. The duty upon bronzes is 45 per cent. A picture, as I have said, has to pay 20 per cent. of its value, but the duty upon its frame is 35 per cent. of its value, and 45 per cent.—if covered with gold leaf. The duty upon groups made from composite materials may be anything from 20 per cent. to 60 per cent., according to the predominating material of which it is composed, and this is left to the Customs' officials to determine. All these are restrictions to business, but it is nevertheless gratifying to note that the sales from the British Art Section were considerably larger than those effected in any other foreign section. This, no doubt, was entirely due to the excellence of our

section, and had it not been for the heavy duty a larger number of sales might have been completed. It is to be hoped that the claims of British artists to fair treatment will not be overlooked, if, as is alleged, modifications in the United States tariff are now in contemplation.

With reference to sales, there is something I would like to say with respect to the amounts which some of our artists ask for their works in comparison with those asked by artists competing in the other sections. From my experience gained at several international exhibitions, I cannot help thinking that many of them stand in their own light by fixing prices which are unlikely to encourage purchasers. Foreign artists of the first rank fix the values of their pictures at these exhibitions at prices which more readily command sales. Their failure at St. Louis is quite an exceptional experience for them. Following the example of France, we also withheld our Art Section from competition for awards, and in this decision we had the hearty support of the Arts and Crafts Committee. I may add that other sections of the Royal Commission, notably the Education Section, also withheld their exhibits from competition.

A loss to the British Art Section was the absence of the works of many eminent artists who were prevented from exhibiting with this country by virtue of their American nationality, and many of them sent their works to the American Section. The list includes John S. Sargent, R.A.; E. A. Abbey, R.A.; the late G. H. Boughton, R.A.; J. J. Shannon, A.R.A.; George Wetherbee, R.S.; J. McClure Hamilton; Daniel Wehrschmidt; Mark Fisher; F. Derwent Wood; W. J. Hennessey; and F. D. Millet.

The question is often asked whether these vast international exhibitions can really be successful, and whether the results they achieve are commensurate with the vast expenditure of time and money which they entail, and whether they are even appreciated as they should be. To those who ask whether the St. Louis Exhibition has been successful, I would reply that you cannot gauge the success of any exhibition merely by the amount of money taken at the turnstiles. Its success can only be measured later, if at all. The new reputations made, the number of orders booked, the fresh business opened up, the money brought into the country, and, above all, the new seed that has been sown, and the lessons that have been taught and learnt—all these are factors that have to be taken into account.

There are many reasons why British artists should participate in these international exhibitions, quite apart from the question of the sale of their works. International exhibitions are international competitions. It is a matter of country versus country. The success of any one section adds prestige to the country it represents, and this is why every patriotic Englishman should endeavour to assist in scoring a success at such exhibitions for the honour of his country. Apart from this, the names of artists who elect to be represented are kept alive, whilst those whose names are not to be found in the catalogue, place themselves at a disadvantage in the public recollection and in the record of history.

The impression produced by our section was distinctly favourable, and the Press, both of this country and of the United States, was alike cordial and just in its appreciation of it.

In a still more official manner was our success brought to the notice of the public by the letter of our Ambassador to the United States, Sir Mortimer Durand, who thus wrote to the Foreign Office from Washington on the 18th November:—

"The British Art Section is generally regarded as containing the best collection of pictures in the Exposition."

For this satisfactory result thanks are due to the 135 private owners, societies, and provincial corporations, who came forward and lent their valuable works for the honour of the nation. The co-operation of our artists must be included in our tribute, for their zeal did much to ensure our success.

Our work will have served its purpose if it has raised the prestige of British Art abroad, and helped to encourage our artists at home.

DISCUSSION.

Mr. WALTER CRANE expressed his pleasure at being present to hear Mr. Spielmann's admirable paper, which was practically a personally conducted tour through the Exhibition. The account given from different points of view, financial, artistic, and organisation, was so complete as to make him feel that he might have saved himself the trouble of going to St. Louis. The series of pictures shown gave an admirable idea of the plan and arrangement of the buildings and their general effect, minus the colour, the absence of which one always allowed for in photographs. He

had been particularly struck with the fine way in which the large gallery in the German Room was set up, and thought English artists might take some valuable hints from their German friends in regard to the decorative or scenic effects produced by the arrangement of their galleries. They adhered to the principle, as far as possible, of hanging only one line of pictures, and the eye line was the ideal line from which to inspect pictures. The numerous works in the British Section no doubt made that impossible, but he did not hesitate to say the effect produced was far finer if there was only one line of pictures. The same principle was adopted in the annual exhibitions at Munich, and the arrangement of the colour in the rooms to suit the pictures was far in advance of what was generally thought necessary in this country. Mr. Spielmann seemed to think that the English Section was not altogether advantageously situated in its position in the Arts Gallery. He did not know whether that was due to the usual Govermental action in such matters. England was not usually first in the field, and he believed that Germany and France sent representatives over to St. Louis and secured the best places long before England did; but if the people of this country only decided late in the day to take an important part in the Exhibition, they could not be surprised if the best places had been already allotted. That was too often the case with English authorities, and it was notorious that it was a very hard matter to screw anything out of the Government for the benefit of the representation of the national art in other countries.

Mr. JOSEPH PENNELL said that as the official representative of the St. Louis Exhibition for Art in this country he could confirm Mr. Crane's statement that it was owing to the dilatory action of the English Government that Great Britain lost the best positions, although the place subsequently allotted was not anything like so bad as the author supposed; in fact, it was an excellent position. As to the staircase, the architect forgot the exit at the back of the building was not thirty inches from the ground, as he was given to understand, but thirty feet, which produced an exciting effect, as Mr. Pennell was told many people fell down it though none dared climb it. Mr. Spielmann had stated that England had placed her Art Section *hors concours*. It was impossible for any country to place itself *hors concours*. As a matter of fact, England refused to compete; and he had an official communication in his pocket stating that not only American artists, but the artists of the whole world, extremely regretted that England did not take part in the competition, especially, as in this particular instance, she had sent abroad the best show which had ever been sent out of the country. The British Section was a splendid exhibit for Great Britain, and as popular and as well patronised as any section of any country which exhibited in the Exhibition. The refusal, therefore, to enter the competition for awards—in this Section of the British exhibits only—produced a most unfavourable effect on the international jury.

The CHAIRMAN, in proposing a vote of thanks to the author for his admirable paper, stated that Mr. Spielmann referred to the plodding perseverance and unlimited patience with which the difficulties connected with the Exhibition were overcome. Mr. Spielmann was so modest that he had made no reference to himself in the whole of the paper, but those particular qualities Mr. Spielmann had shown in the most remarkable manner, and the success of the Fine Art Section was due almost entirely to his labours. It was not the first time Mr. Spielmann had acted in connection with international exhibitions, the first time he (the Chairman) had the pleasure of being associated with him was at the Brussels Exhibition, when the English Section for the first time was very prominent. As Mr. Spielmann had stated was the fact at the St. Louis Exhibition, the English Section at the Brussels Exhibition was the only section ready on the day of opening, and the same remark applied to the Paris Exhibition. For that they had to thank almost entirely Mr. Spielmann's wonderful perseverance and patience in carrying out the details. He also ought to state that Mr. Spielmann received absolutely no remuneration for his admirable work as honorary secretary in connection with the Brussels Exhibition, in fact, he was obliged to give up the post he occupied at the time to devote his energies to the purpose. At the Paris Exhibition he accepted the post of secretary, at a very inadequate remuneration; and with regard to the St. Louis Exhibition, he had worked like a Trojan from beginning to end with absolutely no pay or salary of any kind. He therefore thought the thanks of the country were due to Mr. Spielmann for the work he had done on its behalf.

The resolution of thanks having been carried, Mr. Spielmann briefly acknowledged the compliment, and the meeting terminated.

In reply to Mr. Pennell's remarks, Mr. SPIELMANN writes:—The question of competing for awards by artists is one which furnishes sufficient material for a special paper. Something may be said in its favour, but very much, in my opinion, can be said against it. Scientists and artists, literary men, and members of the professions generally, can hardly compete for awards in the same way as manufacturers of machinery or makers of pickles. It must be remembered, too, that our artists are not only invited to compete with foreigners, but amongst themselves, surely not a very dignified proceeding. I believe the majority of artists recognise this, and consider that they ceased to compete for prizes and medals when they left school, and that they no longer attach any importance or value to them. Medals may have an attraction for art students, but artists of

more mature years prefer to abstain than to have to compete for them. Why should eminent artists who have already received the highest honours that the art world can confer be obliged to submit their works to the uncertainties of an unwieldly international jury, the members of which may, for the most part, be ignorant of the artists, and of their achievements? Apart from these considerations, the constitution of the jury and its methods of procedure should determine the question of competition for awards. When either of these are unsatisfactory, or when the rules or regulations are unpublished, it is better to abstain. The composition of international juries is often most unsatisfactory. It may number from 50 to 75 representatives, amongst whom Great Britain may be entitled to, say, three members only. In such a case they would have a hard struggle, if they succeeded at all, in obtaining adequate recognition. Distant countries are frequently represented by jurors appointed on their behalf by the local exhibition officials, and sometimes the jurors so appointed are neither artists nor have any knowledge of Art. There are two methods of awarding medals. When they are unlimited in number they are frequently scrambled for by the jurors in the most unseemly manner, quite apart from the question of merit. When the number is restricted it is equally unsatisfactory. The jurors may determine to apportion to Great Britain, say, twelve gold medals and twenty-four silver medals. In a collection of high average excellence this is particularly unfair. Instead of twelve pictures of the highest merit there may be twenty. To say that twelve of them should have gold medals, and the remaining eight of equal merit nothing at all, solely because there are no more medals to have, is manifestly absurd. Under such conditions it is better and more dignified to withhold the entire Art Section from competition. These remarks do not refer in any way to St. Louis, but to the methods adopted at international exhibitions generally, and apply specially to the Art Section.

THE PROGRESS OF ORTHOCHROMATIC PHOTOGRAPHY.*

Dr. Koenig, whose name will be readily recognised as the discoverer of the isocyanine dyes, which are now so much to the fore, contributes a useful article to the *Deutscher Camera-Almanach*, of which the following is an extract.

Every photographer and amateur, who knows anything at all of photography, understands what is meant by orthochromatic photography and orthochromatic plates, but it is not every one that rightly understands the subject, for some use orthochromatic plates and a yellow screen, while others see no advantage in the same. The real truth lies probably between the two, and it is only actual experience that enables one to appreciate the practical results of this scientific advance.

It is well known that, notwithstanding the correctness of the drawing and perspective given by photography, it has two great faults, the one the exaggerated difference between light and shade, and the other that it does not render colours in the same gradation or brightness as seen by the human eye. This false rendering of colour is particularly noticeable with yellows, or bright reds and blues; to our eyes yellows and red appear bright, and blues dark; by photography blue is rendered very light and yellow and red quite dark, because the gelatino-bromide is only sensitive to blue and violet and not for red, yellow, and green.

The Discovery of Orthochromatism.—In 1873, H. W. Vogel discovered that many dyes possessed the property of making silver bromide sensitive to red, yellow, and green, or, as is usually called, "sensitised" for these rays. The first observation was made with collodio-bromide of silver, but other experimenters soon proved that gelatino-bromide of silver behaved in the same way, and now a very large number of dyes are known which sensitise gelatino-bromide of silver for the different regions of the spectrum. All these dyes also stain silver bromide direct, in the absence of gelatine, but it is a remarkable fact that not all dyes which stain silver bromide also sensitise. Whilst it has not yet been satisfactorily explained why only certain dyes possess sensitising properties, yet there is a certain connection between the absorption spectrum of the dye and the band of sensitiveness. The maximum of the sensitising lies at about the same place as the maximum absorption band of the dye solution; thus generally sensitisers for green and greenish yellow are red, and sensitisers for yellow and red are violet or blue.

The most important sensitisers for green and yellow belong to the phthaleins, the best sensitisers for red are the cyanines. To the first-class belong eosine (tetrabromofluorescine), di-iodofluorescine, and erythrosine (tetraiodofluorescine). The maximum of sensitising lies with eosine in the green, and does not reach the Fraunhofer line D; with erythrosine the sensitiveness extends to beyond D; di-iodo-fluorescine lies between the two. Erythrosine must be considered as the strongest and best sensitiser for practical work.

The various dyes may be used in one of two ways: they may be either added to the emulsion before coating or ordinary dry plates may be bathed in very dilute solutions of the dye. The amount of dye to be used must be very minute, too much dye lowers considerably the general sensitiveness of the plate, as the deeply-dyed film prevents the penetration of the light. With all dyes the best results are obtained by bathing the plates.

The Yellow Screen.—If a colour chart is photographed with an erythrosine-bathed plate chrome yellow will appear almost as bright as ultramarine; red, on the other hand, appears absolutely black. If

* From the *British Journal of Photography*.

it is desired to drive the orthochromatic action further, and to render yellow considerably brighter than blue, a yellow colour filter must be used, which damps the blue. The action of the colour screen does not seem to be thoroughly understood. If we realise that the so-called orthochromatic plates are always pre-eminently sensitive to blue, and that while on account of the proportion of blue rays in it must always exert the strongest photographic action, we shall easily understand that by the insertion of a yellow screen, which partially absorbs the blue rays, the exposure must be prolonged in order to obtain the same density in the whites. If two exposures are made on orthochromatic plates, one without a filter, the other with a bright yellow filter, and the second exposure twice as long, so that white has equal density in both, the blues will appear much weaker on the second plate than on the first; yellow, on the other hand, will appear much the stronger on the second than the first. By the increased exposure the yellow rays, which are not absorbed by the yellow screen, have acted more strongly on the yellow sensitive film.

It is obvious, therefore, without further explanation, that a plate which is only slightly sensitive for yellow requires a darker yellow screen (and therefore a longer exposure) for correct colour rendering than a plate which is strongly sensitive to yellow.

Commercially, as a rule, plates sensitive to greenish yellow, and which are usually sensitised with erythrosine, are called "orthochromatic," although they are not sensitive to red. Most of these plates only give a satisfactory orthochromatic action with a dark yellow screen. The idea has been adopted for some plates of placing the yellow screen in the sensitive film, and the plates thus prepared permit of good colour rendering without a yellow screen.

The Cyanines.—We have mentioned above the second group of sensitisers—the cyanines. To this class belongs cyanine, a beautiful blue dye, which is an excellent sensitiser for yellow, orange, and red. Unfortunately this dye does not give reliable results, as the plates sensitised with it does not keep, and are prone to spots and fog. More important and more valuable from a practical point of view are the violet isocyanines, which are derived from chinaldin, because they not only possess the property of sensitising silver bromide for red, orange, and yellow, but make it also sensitive to green. The isocyanines combine therefore to some extent the properties of erythrosine with those of cyanine. With ethyl red, which was introduced by Professor Miethe, the nearly complete band of sensitiveness extends from the blue to the orange to just beyond the D line, the band of orthochrome T extends further into the red, and that of pinachrome extends even, with a short exposure, to beyond the C line in the red. Practically this means that plates sensitised with pinachrome are much more sensitive to orange and red than orthochrome plates, and more so still than ethyl red plates. Pinachrome must be considered as the best sensitiser known up to the present.

With these dyes the bathed plates are considerably more sensitive to colour than those coated with dyed emulsion.

With the aid of the said isocyanines or of mixture of dyes which supplement their sensitising properties, plates can be prepared which are sensitive to all the colours of the spectrum, even if not to quite the same degree. These "panchromatic" plates have also their maximum sensitiveness in the blue. The principal use of such plates is for colour photography, but their use is absolutely indispensable when orange and red have to be reproduced; for such work the inter-position of an orange filter, to damp the blue and green, is always essential. It may be mentioned that up to the present no plate exists which is even approximately as sensitive for red as for blue.

The Use of Orthochromatic Plates.—Very different opinions as to the use of orthocromatic plates are held generally. Undoubtedly ortho-plates in conjunction with a colour filter are useful in innumerable cases, and frequently absolutely essential. It does not appear, however, correct to the author to recommend the universal use of ortho-plates for all landscape, and especially for mountain work, for it makes the photographer think that it is actually possible to take ordinary landscapes with an ordinary plate. When yellow and yellowish-green tones predominate, as in autumn or spring, or evening scenes, the ortho-plate can always be used with advantage, and in portraiture their use saves much retouching. Ortho-plates are absolutely essential in the reproduction of all coloured objects. The frequently-described great advantages of the orthochromatic process in the taking of summer-green landscapes, of mountain peaks and distance, the author denies, although he is convinced that this heretical opinion will be frequently disputed.

As regards landscapes in summer, we ought not to forget that every kind of plate is very little sensitive to the dark green of summer leaves, and further that in a bright light, and much more in sunshine, it is the white light reflected from the leaves much more than the green that produces the photographic image. As a matter of fact, the author has never succeeded in confirming a difference between orthochromatic and ordinary plates for ordinary landscape work.

It is just the same with mountains and distant scenery; with these the yellow screen and ortho-plates should work wonders. The author certainly believes that many amateurs obtain better results with the aid of these two, but the pictures are only better because the true exposure is mostly involuntarily rendered shorter by the yellow screen, or, what comes to the same thing, the ortho-plates are frequently less sensitive than the ordinary. If the ordinary plate is only exposed for a sufficiently short time the cloudless blue sky will also appear darker in the print than the snow peaks glistening in the sun; and if the sky during the exposure is whitish, so that the mountain is visually almost impossible to detect, then no orthochromatic plate and no yellow screen is of any avail to obtain a difference.

It may be argued that the use of orthochromatic plates can at least do no harm. Opposed to this are the facts that ortho-plates are mostly dearer than ordinary, and frequently are inferior as regards keeping properties and sensitiveness, though, as we have already seen, this last may be an advantage under certain conditions. Finally, the exposure is considerably lengthened by the yellow screen which must generally be used.

The photographer will do well to consider in every case whether the use of ortho-plates appears advantageous or not. As a guide to this point a few short rules may be useful, which embody what we have said.

When to Use Ortho-Plates.—1. According to the prevailing method of speaking we differentiate between orthochromatic and panchromatic plates. The former are only sensitive for yellow and yellow-green; the latter are also sensitive to orange and red.

2. The commercial orthochromatic plates only permit of an absolutely correct colour rendering, as regards yellow and blue, when used with a yellow screen of more or less dark shade.

3. The use of orthochromatic plates is above all things necessary when the reproduction of yellow and yellow-green is in question. For bluish green and dark green the plates, even with a yellow screen, are very slightly sensitive, so that for ordinary landscape work, further for mountain and distant scenery, the ortho-plates offer no important advantages.

4. Panchromatic plates are certainly necessary when orange and red are to be reproduced, and in this case the use of colour filters is absolutely essential.

5. Bathed plates are always more sensitive than plates dyed in the emulsion.

Formulæ for Bathing.—Always use perfectly clean working plates, and bathe them in the dark, keeping the solution continuously on the rock After bathing, the plates should be washed in running or frequently changed water for two or three minutes, and dried in a well-ventilated place free from dust.

Erythrosine Bath.

Water	100 ccm
Ammonia	2 ccm.
Erythrosine solution (1 : 1,000)	6-8 ccm.

Bathe for 2-3 minutes.

Pinachrome Bath.

Water	100 ccm.
Ammonia	1 ccm.
Pinachrome solution (1 : 1,000 alcohol)	2 ccm.

Bathe for 3-4 minutes.

Ethyl red and orthochrome plates are prepared in exactly the same way as the pinachrome plates.

GENERAL NOTES.

UNITED STATES RAILWAY SPEEDS.—Reporting on the railways of the United States (No. 627, Miscellaneous Series), the Hon. Robert Collier says that, "with certain exceptions," they are "not particularly fast." But the exceptions are noteworthy. The best speeds appear to be found between Philadelphia and the sea-side resorts of Atlantic City and Cape May, where in summer there are a certain number of very fast trains. From Atlantic City to Camden (a suburb of Philadelphia) *viâ* the Philadelphia and Reading line, one train last summer was for a time given only 49 minutes, start to stop, for the 55½ miles, while between Camden and Cape May, on the Pennsylvanian Railway, there is a train which covers the 72·2 miles from Camden to Angelsea Junction in 73 minutes, start to stop. On the New York Central route, between New York and Chicago, the "20th Century Limited," covers the whole 980 miles in 20 hours in either direction. There are a considerable number of trains making start to stop runs at over 50 miles an hour, and the "Empire State Express" even performs two runs at 57 miles an hour. Further west the trains get slower and less frequent. While electricity is almost exclusively used as the motive power of the very numerous tramways in every part of the country, on railways it is used to a very limited extent only. The overhead workings of New York and Chicago are the most conspicuous instances. For working trains through tunnels where the traffic is intense, and for tubular work in general it is probable that electricity will be more and more used as the motive power, but the prospect of anything like a revolution in the direction of its being employed to work long distance railway traffic seems remote.

IRELAND AND POTATOES.—With a steadily dwindling population it is not surprising that the area under potatoes in Ireland is much smaller than it used to be, but they remain the staple crop, and the "Champion" variety continues to be the m st popular. In 1883 the total area under potatoes was 806,467 acres, in 1904 it had fallen to 618,540 acres, a decrease of over 23 per cent. In 1883 the proportion of the entire crop under "Champion" was 78·5, in 1904 it had fallen to 61·3; so that even now only 38·7 per cent. of the area under the potato crop is left for all other varieties. The "Champion" potato was first introduced in quantity into Ireland in the year 1880, after the failure of the potato crop in 1879. Since that year it has constituted the main potato crop of the country, but, as shown above, it is gradually losing its hold upon the cultivator. The acreage under each of the principal varieties of potatoes planted in 1904, other than the "Champion," was as follows:—Up-to-date 9·6 per cent., Beauty of Bute 7·0, Flounders 6·8, Sutton's Abundance 4·5, Irish Whites 3·0, Skerry Blues 2·9.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock :—

MARCH 8.—"Ethics of Japanese Society." By BARON SUYEMATSU. The RIGHT HON. LORD REDESDALE will preside.

MARCH 15.—"Methods of Design in Mohammedan Art." By E. H. HANKIN. SIR GEORGE BIRDWOOD, K.C.I.E., C.S.I., Vice-President of the Society, in the chair.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock :—

MARCH 16.—"Manipur and its Tribes." By T. C. HODSON (late I.C.S.).

COLONIAL SECTION.

Tuesday afternoons at 4.30 o'clock :—

MARCH 28.—The Manufactures of Greater Britain. —II. Australasia." By the HON. WALTER HARTWELL JAMES, K.C., Agent-General for and late Premier of Western Australia.

APPLIED ART SECTION.

Tuesdays, at 4.30 or 8 o'clock :—

MARCH 21, 8 p.m.—"West Country Screens and Rood Lofts." By F. BLIGH BOND, F.R.I.B.A. G. F. BODLEY, R.A., will preside.

CANTOR LECTURES.

Monday evenings, at 8 o'clock :—

DUGALD CLERK, M.Inst.C.E., "Internal Combustion Engines." Four Lectures.

LECTURE IV.—MARCH 6.—*Future Developments*—Suction producers—Blast furnace gas—Producer gas in power-stations—Marine gas and oil engines—Line of advance.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MARCH 6...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Mr. Dugald Clerk, "Internal Combustion Engines." (Lecture IV.)

Royal Institution, Albemarle-street, W., 5 p.m. General Monthly Meeting.

Engineers, in the Theatre of the United Service Institution, Whitehall, S.W., 7½ p.m. Mr. Benjamin H. Thwaite, "The Transport possibilities of our Inland Navigable Waterways."

Chemical Industry (London Section), Burlington-house, W., 8 p.m. 1. Prof. H. E. Armstrong, "Mechanics of Fire." 2. Dr. George McGowan, and Mr. R. B. Floris, "The Estimation of Arsenic Fuels—A shortened method."

Faraday Society, 92, Victoria-street, S.W., 8½ p.m. Mr. F. W. Harbord, "Recent Developments in Electric Smelting in Connection with Iron and Steel."

British Architects, 9, Conduit-street, W., 8 p.m.

Camera Club, Charing-cross-road, W.C., 8½ p.m.

Medical, 11, Chandos-street, W., 5 p.m. Annual Meeting.

Victoria Institute, 8, Adelphi-terrace, W.C., 4½ p.m. Mr. Charles B. Warring, "Geological Exterminations."

TUESDAY, MARCH 7...Royal Institution, Albemarle-street, W., 5 p.m. Prof. Pearson, "Some Recent Biometric Studies." (Lecture II.)

Alpine Club, 23, Savile-row, W., 8½ p.m. Lecture by Captain Scott.

Designers, R.I.B.A. Galleries, Suffolk-street, Pall-mall, S.W., 8 p.m. Mr. Strange, "Ornament for Old English Rood Screens."

Civil Engineers, 25, Great George-street, S.W., Discussion on Mr. Richard William Allen's paper, "Surface-Condensing Plants, and the Value of the Vacuum Produced."

Pathological, 20, Hanover-square, W., 8½ p.m.

Zoological, 3, Hanover-square, W., 8½ p.m.

Pharmaceutical, 17, Bloomsbury-square, W.C., 8 p.m.

WEDNESDAY, MARCH 8...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Baron Suyematsu, "Ethics of Japanese Society."

Biblical Archæology, 37, Great Russell-street, W.C., 4½ p.m.

Geological, Burlington-house, W., 8 p.m.

Japan Society, 20, Hanover-square, W., 8½ p.m. Prof. J. H. Longford, "England's Record in Japan."

Royal Literary Fund, 7, Adelphi-terrace, W.C., 3 p.m. Annual Meeting.

THURSDAY, MARCH 9...Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

Royal Institution, Albemarle-street, W., 5 p.m. Prof. H. H. Turner, "Recent Astronomical Progress." (Lecture II.)

Electrical Engineers, 25, Great George-street, S.W., 8 p.m. 1. Report on Experiments carried out at the National Physical Laboratory. 2. Dr. R. T. Glazebrook, "The effect of Heat on the Electrical and Mechanical Properties of Dielectrics," and 3, "The Temperature Distribution in the Interior of Field Coils." 4. Mr. R. Goldschmidt, "Temperature Curves and the Rating of Electrical Machinery."

Mathematical, 22, Albemarle-street, W., 5½ p.m.

Camera Club, Charing-cross-road, W.C., 8½ p.m.

FRIDAY, MARCH 10...Royal Institution, Albemarle-street, W., 8 p.m. Weekly Meeting. 9 p.m. Professor J. J. Thomson, "The Structure of the Atom."

Civil Engineers, 25, Great George-street, S.W., 8 p.m. (Students' Meeting.) 1. Mr. F. G. Helsby, "The Purification of Sewage." 2. Mr. F. O. Kirby, "The Purification of Sewage by Hydrolysis and Oxidation."

Astronomical, Burlington-house, W., 8 p.m.

Architectural Association, 18, Tufton-street, S.W., 7½ p.m. Mr. H. V. Lancaster, "Law Courts."

Clinical, 20, Hanover-square, W., 8½ p.m.

Royal College of Science, Exhibition-road, South Kensington, S.W., 8 p.m. Dr. C. Chree, "The Stresses in the Earth's Crust before and after the sinking of a Bore-hole." 2. Mr. J. Morrow, "The Lateral Vibration of Bars of Uniform and Varying Sectional Area." 3. Mr. A. Campbell, "Direct Reading Resistance-Thermometers, with an Appendix on Composite Thermocouples."

SATURDAY, MARCH 11...Royal Institution, Albemarle-street, W., 3 p.m. Prof. J. J. Thomson, "Electrical Properties of Radio Active Substances." (Lecture I.)

Journal of the Society of Arts.

No. 2,729. VOL. LIII.

FRIDAY, MARCH 10, 1905.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

NOTICES.

NEXT WEEK.

MONDAY, MARCH 13, 8 p.m. (Cantor Lecture.) HERBERT LAWS WEBB, "Telephony," Lecture I.

WEDNESDAY, MARCH 15, 8 p.m. (Ordinary Meeting.) E. H. HANKIN, "Methods of Design in Mohammedan Art."

THURSDAY, MARCH 16, 4.30 p.m. (Indian Section.) T. C. HODSON, "Manipur and its Tribes."

Further details of the Society's meetings will be found at the end of this number.

CANTOR LECTURES.

On Monday evening, March 6, Mr. DUGALD CLERK, M.Inst.C.E., delivered the fourth and last lecture of his course on "Internal Combustion Engines."

The CHAIRMAN (Professor W. G. Adams, F.R.S.) proposed a vote of thanks to the lecturer for his interesting and important course of lectures, which was carried unanimously.

The lectures will be published in the *Journal* during the summer recess.

COVERS FOR JOURNAL.

For the convenience of members wishing to bind their volumes of the *Journal*, cloth covers will be supplied, post free, for 1s. 6d. each, on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

APPLIED ART SECTION.

Tuesday, February 21st; JOHN BELCHER, A.R.A., Pres.R.I.B.A., in the chair.

The paper read was—

THE QUEEN VICTORIA MEMORIAL AS COMPARED WITH OTHER ROYAL MEMORIALS ABROAD.

By MARION H. SPIELMANN, F.S.A.

On the morrow of the death of Queen Victoria, it was the universal feeling that some monument, some visible memorial of her greatness and her goodness, and of the enduring love and respect of her mourning subjects, should be set up here in the metropolis of her Empire.

If ever sovereign could say, in the words of Horace, *Exegi monumentum ære perennius*—"I have reared a memorial of myself more enduring than bronze"—that sovereign, we knew, was Queen Victoria; but it was not solely for her honour, but for our own satisfaction and delight, that the propriety, the exigency, of such a memorial forced itself upon us as a duty and a pride. It is, of course, true that those who deserve a statue do not need one; but the memorial is the consolation of the survivors, and, if rightly conceived, is as noble a tribute to their own unselfish gratitude as it is to the glory and greatness of the man or woman whom we design to honour.

If this much is conceded, is it not a severe commentary on, a tacit condemnation of, the utilitarian habit among us, which so often seeks to make capital out of the loss of some great sovereign or statesman or philanthropist, and to turn the kindly emotions of the public into cash for the purpose of some public work

or charitable institution? These are most excellent undertakings, of course, deserving of all our enthusiasm; but surely it is not quite worthy to make use of the passing of the dead for the best concrete advantage of the living. If a hospital wing, or a soup kitchen, or national theatre, or public library, or village clock are needed, they may be erected by the public-spirited and the charitable without the pretence of seizing on the memory of a great and famous one just dead and feeding our needs on that. I am told that when the Prince Consort died, a small southern county town, in bad sanitary condition, actually evolved the idea of a public subscription for what was to be called an "Albert Memorial Sewer." Could anything be more revolting? And yet is there one of us here present who, after the death of Queen Victoria, did not receive many such appeals as I have mentioned, for the maintenance of worthy institutions, or the restoration of churches, hospitals, and the like? If it is answered that this use of the lever is the only way of getting things done, and it must be done, let it be openly recognised, without any of the evasion which Molière's "Alceste" would have openly called hypocrisy, that these works are not so much for the glory of the departed as for the better use of man, and that the practical spirit of affairs has been allowed to overlay the more generous and unselfish sentiments involved in a public statue or kindred national memorial.

It was, therefore, a happy inspiration that directed the form of the Queen Victoria Memorial—a great work, and a monument not devoted to the interests of any particular section of the public, but open to the enjoyment of the whole world who chose to come and gaze and remember; a work whose only use is beauty, and only purpose glorification—not only for our present satisfaction, but for a symbol to future centuries, when our hospital buildings, our soup kitchens, and our clocks of to-day, will be torn down and cast aside.

A heavy responsibility lay upon the distinguished committee appointed to determine the exact form the memorial was to take, but there was a general confidence that the demands and requirements would be fully appreciated. Examples abounded; examples that might be followed, and examples that must be shunned. For there exist—as I shall presently show—a few noble monuments to great rulers departed, and many failures—monstrous, effete, ridiculous, vulgar, in turn—which seem to have served less to warn the public against the false in sentiment and the bad in art, than to accustom and reconcile them to the sight of what is poor, pompous, and meretricious. It is for this reason that the nation expects that the memorial to Queen Victoria shall be the finest expression of national feeling and of national art to which the race can give utterance. The case, it is felt, demands the combination of forces of the best of our sculptors and architects available, who are at once artists in imagination and execution. As for the sculptor, on whoever the choice might fall, he was to be a man capable of understanding two things. He must appreciate beauty and dignity in sculpture in their highest and noblest form, and recognise the border-line that exists between the dramatic and the truly sculpturesque in plastic art, or the result, it was felt, would certainly be a failure; and he must feel, and so be able to appreciate and translate, the double sentiment to be expressed in this monument—the true greatness of the Queen, and the sentiments of her people.

The committee consisted of:—Viscount Esher, Lord Windsor, Lord Redesdale, Sir Edward Poynter, Sir William Emerson, Sir Lawrence Alma Tadema, Mr. Sydney Colvin, and General Sir Arthur Ellis—a committee which commanded the confidence alike of artists and public.
